EYE HOSPITAL, BRISTOL.—The Duchess of Beaufort on Oct. 21st opened the new Eye Hospital in Lower Maudlin-street, Bristol, which has been erected at a cost of £55,000. The old premises next door are being altered to provide accommodation for the nursing and resident staff. The sum of £23,000 is still required.

HÆMOCHROMATOSIS AND HEREDITY

BY R. D. LAWRENCE, M.D. Aberd., F.R.C.P. Lond.

ASSISTANT PHYSICIAN TO KING'S COLLEGE HOSPITAL, LONDON

BRONZED diabetes (hæmochromatosis) is a very rare disease, most probably due to an inborn error of metabolism, mainly of iron. Sheldon's¹ recent publications provide the most complete survey of the disease, and he points out how a familial or hereditary incidence is to be expected in a presumably congenital type of disease. Only 5 certain familial cases in brothers are admitted by him and only 3 hereditary cases, not entirely proven, in succeeding generations. I therefore think it important to present evidence of definite familial and perhaps hereditary incidence in one family under my observation. Admittedly the clinical evidence is incomplete and the history doubtful in some members, but from the death of many of the family and some of their doctors, the evidence is as complete as it is ever likely to be.

The majority of cases of hæmochromatosis are diagnosed from the appearance of diabetic symptoms, and in this way I first came in touch with this family. I recognised the affected member as a case of hæmochromatosis, and the family history showed that several other relations were known to have passed sugar. Altogether the history of 116 individuals in 6 generations was obtained as regards glycosuria. But with all the necessary inaccuracies involved in such an extensive pedigree we need not be concerned, and the appended pedigree is confined to the three relevant generations. It is worth describing the numbered members in what detail is possible. It should be remembered that the four classical signs of hæmochromatosis—pigmentation, cirrhosis of the liver, diabetes, and sexual hypoplasia—may not be found in every case, and that two and even one such symptom of the complete syndrome in such a family may have significance. Much of the evidence has been obtained by correspondence, and I am as critical of its value as any reader.

THE FAMILY PEDIGREE

The accompanying pedigree is arranged according to age. There are no intermarriages in the family.

M F
 ■ = HÆMOCHROMATOSIS
 ☐ ☉ = SIGNS OF HÆMOCHROMATOSIS
 □ ○ = UNAFFECTED

The first generation is not known to have had diabetes, glycosuria, or pigmentation. In the second generation only II 2 was known to have diabetes for a number of years, and died aged 70. She was slightly jaundiced and had a large liver (three fingers-breadth). Severe anaemia was present and the differential diagnosis made shortly before death in 1916 was "pernicious anaemia or malignant disease." No note was made of any special pigmentation

except slight jaundice and a lemon-yellow tint, nor of the consistency of the liver.

The third generation merits fuller description. Unfortunately many details are missing and cannot be ascertained owing to the death of some of their doctors and the absence or destruction of notes. One of the recorded members—a doctor—has given much useful detail.

No. 1, the eldest, a female, aged 70, has pernicious anaemia. Glycosuria is absent, and she is not known to have a large liver or pigmentation.

No. 2, male, died aged 64, from what was tentatively diagnosed as "neoplasm of the liver, secondary to ? stomach." A large mass including the liver and ? spleen was present in upper abdomen; this was especially hard, irregular, and tender at the right flank. Ascites and jaundice were present at the end, but there is no mention in the short notes available of glycosuria or pigmentation. Wassermann reaction negative. His brother doubted the diagnosis of carcinoma because cachexia was absent and because the abdominal swelling had been present too long to be a carcinoma. "For several years he made his tailor alter the cut of his clothes to conceal the prominence of the upper abdomen."

No. 3, female, in good health.

No. 4, male, aged 62, in good health, has slight glycosuria, no enlarged liver, some brownish patches of pigmentation on face only.

No. 5, male, died aged 58, of some intercurrent obscure febrile illness. He was a typical case of hæmochromatosis with a very large liver and insulin had been required for 2½ years to control the diabetes.

No. 6, female, good health, no abnormality.

No. 7, male, good health, no signs of hæmochromatosis, but a slight trace of sugar has been found in his urine.

No. 8, male, a typical case of hæmochromatosis. Known to have large liver and diabetes since age of 48. Now aged 55, and keeps well and leads an active life with 40-50 units of insulin a day.

No. 9, male, lives in America and said to have good health.

Of the next generation none of the 13 sibs are known to pass sugar. They are mostly under thirty years of age.

Summary of above pedigree and discussion.—Of the 6 males, only 2 present the complete syndrome; 1 other died with a very large liver, 1 has glycosuria and slight pigmentation, 1 has slight glycosuria only. The sixth has no known abnormality. Of the females, only the mother showed any symptoms of hæmochromatosis—i.e., diabetes and hepatomegaly. The three sisters have not a single suggestive symptom.

If we accept only the 2 proven cases the pedigree is interesting enough to merit publication. But if we accept other members of the family who show one or a few symptoms as having hæmochromatosis, this pedigree becomes extremely interesting and suggestive.

HEREDITY AND THE NATURE OF HÆMOCHROMATOSIS

The most widely accepted view of hæmochromatosis is that it is a congenital disease, an inborn error of iron metabolism, a deposition of iron pigments in various tissues which has been going on from birth but only accumulates sufficiently to cause disease in middle age. If so, one would expect to find cases with a hereditary influence, and Sheldon has collected such evidence in 5 cases.

A striking feature of the disease is an overwhelming preponderance in males, a few females only being affected. This has never been explained, but in view of my recorded pedigree it is tempting to suggest that the disease is *hereditarily sex-linked* and is comparable with hæmophilia in this respect. One of Sheldon's¹ patients had a brother who died of

diabetes and whose mother and aunt had a long history of enlarged liver. Frisch's² case is still more suggestive of a sex-linked heredity. He describes a family, known locally as the "black family," in whom 7 sibs and their mother were strikingly pigmented. One brother died of hæmochromatosis; two others were pigmented and had large livers, but no glycosuria. Unfortunately the others could not be examined and even their sex is not mentioned.

The above evidence suggests that hæmochromatosis may be a sex-linked hereditary disease, like hæmophilia, transmitted by females and affecting mostly males. This hypothesis has the merit of fitting in both with the apparently congenital nature of this inborn error of metabolism and the overwhelmingly male preponderance.

It would be possible to produce arguments, genetical and otherwise, both for and against this hypothesis. This is not worth while until more evidence is accumulated from the study of pedigrees in hæmochromatosis to refute or confirm this suggestion.

SUMMARY

(1) A family of nine is described in which two brothers had proven hæmochromatosis. (2) Three other brothers and the mother, but none of the sisters, had some signs of the disease. This suggests that hæmochromatosis may be a sex-linked hereditary disease, transmitted by females and affecting mostly males.

Clinical and Laboratory Notes

DEATH AFTER INJECTION OF ATEBRIN MUSSONATE

Br P. B. FERNANDO, M.B., M.R.C.P. Lond.,
D.T.M. & H.

PHYSICIAN, GENERAL HOSPITAL, COLOMBO; AND

E. M. WIJERAMA, M.D., M.R.C.P. Lond.,
D.T.M. & H.

PATHOLOGIST TO THE HOSPITAL

ATEBRIN MUSSONATE has proved its value in the treatment of malaria; but like most other powerful drugs it must be used judiciously if toxic effects are to be avoided. Experience in the Ceylon epidemic of 1934-35 has shown that atebirin should not be given in cases of advanced hookworm disease or where there is disturbance of renal function; but unfortunately, even in cases where no contra-indications have been apparent, untoward results have occasionally followed its use.

A. B., aged 20, was admitted to hospital on July 14th, 1935, after three days' fever, with rigors, and two days' vomiting. During an attack of malaria two months previously he had two intramuscular injections of atebirin mussonate at Kurnegalle Hospital, after which he was free from fever till the beginning of the present attack.

On admission he seemed to be deeply jaundiced (skin, conjunctiva, sclerotics, &c.) and appeared very ill. His mind was clear and he talked coherently but with difficulty; he had a queer expression on his face, lying in bed with the minimum of movement and staring into space. The heart was within normal limits and there were no adventitious sounds; the pulse-rate was 130 and the

blood pressure 120/50. The temperature was 99°F. and the respiration-rate 20. Nothing abnormal was detected in the lungs. The liver was not palpable or enlarged; there was tenderness over its lower border but no rigidity. The spleen was palpable three fingers below the costal margin. No malarial parasites were found in the blood. A van den Bergh test showed: direct, immediate positive; indirect, positive. No albumin, sugar, bile, or atebirin was found in the urine.

In view of the yellow staining, associated with absence of bile in the urine, the case was diagnosed as one of atebirin poisoning. The absence of atebirin in the urine was attributed to failure of the kidneys to excrete it.

Progress and treatment.—The patient was put on quinine *grs.* 7 t.d.s., with *tinct. digitalis* m10 t.d.s. Glucose and sodium bicarbonate in normal saline were given freely by mouth; also an ounce of concentrated mag. sulph. solution. Next day he was gradually getting worse, the pulse being very rapid and weak. Digitalin injections were given in addition to other stimulants. On the following day (July 16th) he died.

Post-mortem findings (July 17th).—The subcutaneous tissues were bright yellow, of a colour quite unlike that seen in jaundice. The brain (2½ lb.) was yellowish and the ependymal lining of the ventricles, the choroid plexus, and the fluid contents of the ventricles were stained yellow. A "crush" preparation did not show either parasites or pigment in the capillaries, and histological sections revealed no microscopic changes. The surface of the tongue, the mucous lining of the pharynx, œsophagus, trachea, bronchi, and their secretions were all yellow-stained. Each pleural cavity contained about 3 oz. of brownish-yellow fluid which on chemical examination for atebirin gave a positive reaction. The lungs were yellow and œdematous, and the pericardium contained about an ounce of yellowish fluid which also gave a positive chemical reaction for atebirin. The epicardial fat had the characteristic yellow colour; the myocardium and the valves showed no naked-eye changes. No free fluid was found in the peritoneal cavity. The liver was moderately enlarged and was congested. Histologically there was accumulation of malarial pigment in the interstitial tissue and in Kupffer cells; there was also an increase of interstitial tissue. The spleen was enlarged and slaty in colour. A stained smear showed malarial pigment but no parasites; the pigment was irregularly distributed throughout the organ within reticulum cells. Secondary follicles of the malpighian bodies showed fatty degeneration, the splenic pulp contained a certain amount of blood and also some areas of hæmopoietic tissue. The kidneys were coloured yellow, but no other macroscopic change was seen. Microscopically there was proliferation of the cells lining Bowman's capsule, forming several layers of cells. The glomeruli showed no marked lobulation; there was fatty infiltration of the tubular epithelium. No malarial pigment was seen. The contents of the urinary bladder contained no atebirin or bile.

Test for atebirin.—The method adopted for the demonstration of atebirin was as follows. Ten cubic centimetres of the fluid, if not already alkaline, is alkalinised by adding potassium carbonate. Amyl alcohol (2 c.cm.) is then shaken up with the alkaline fluid, and the presence of atebirin is recognised by the green fluorescence of the alcoholic extract when held against a black background.

The high concentration of atebirin in the tissues and tissue fluids as found at autopsy is in striking contrast with the absence of even a trace of atebirin in the urine either before or after death. It is hard to explain why it was that this drug failed to pass the renal filter, especially as examination of the kidneys reveals no very advanced lesions.

It seems difficult to be certain beforehand whether a patient will react badly to atebirin, and also difficult to increase its excretion once a full therapeutic dose has been injected. These are serious disadvantages to the extensive use of atebirin by injection.

We acknowledge with thanks our indebtedness to Prof. E. K. Wolff, of the Ceylon Medical College, for his post-mortem notes and his report on the microscopical sections.

UNUSUAL SUBCUTANEOUS RHEUMATIC NODULES

By GEORGE DAVISON, M.D. Durh.

MEDICAL REGISTRAR, ROYAL VICTORIA INFIRMARY,
NEWCASTLE-ON-TYNE

It is many years since the subcutaneous rheumatic nodule was first described, and its nature and significance are widely appreciated. The typical rheumatic nodule varies in size from "a pin's head to an almond"; it is seen over bony prominences and tendons; it is not attached to the skin, and may or may not be fixed to the underlying bone—this probably depending on whether it is situated in a tendon sheath or aponeurosis, or whether it is subperiosteal.

Once thought to be a fibrous structure, the nodule is now known to be a focus of low-grade inflammatory change. Histologically, it shows a structureless background, generally believed to be composed of fibrin; this is invaded by granulation tissue, and is widely infiltrated with cells, chiefly macrophages, plasma cells, and lymphocytes. The structure is thus similar to that of the Aschoff nodes seen in the myocardium. Findlay¹ considers that there is also oedema of the tissues composing the nodule; this would account for the ease with which it can be palpated below the skin as contrasted with the difficulty experienced in dissecting it out at post-mortem or biopsy. The presence of nodules usually indicates active carditis and seriously affects the prognosis. This, of course, is readily understood when the nature of the nodules is considered; they are manifestations in the subcutaneous tissue of the same inflammatory process as is occurring in the heart. The following case is recorded because of the unusual nature of some of the nodules present.

A boy, aged 8 years, was admitted to the Hospital for Sick Children, Great Ormond-street, under the care of Dr. W. J. Pearson on Dec. 15th, 1934. In the previous June he had had tonsillitis and swelling of his hands and ankles. In July he had had scarlet fever. Since then there had been some swelling of his ankles, elbows, and knees, with pain on movement; he had tired easily and become breathless on exertion; twitching of his arms and legs had been noticed,

FIG. 1.—Occipital nodules.

and small nodules seen on his hands and feet. There was no previous history of rheumatic fever. On admission he was seen to be a fairly nourished but rather pale child. Typical rheumatic nodules of the type described were present over the occiput, right acromion, elbows, knees, and the extensor tendons of both hands and feet. Some of the occipital nodules were large (Fig. 1); some were freely movable, others attached

to the skull. The temperature was 101° F. and the pulse-rate 135. His heart showed evidence of an old-standing mitral lesion; the apex-beat was half an inch outside the nipple line, and a loud blowing systolic and short diastolic murmur could be heard in the mitral area.

The temperature fell to normal in a week, and in a fortnight the pulse-rate had fallen to a range of from

FIG. 2.—Two nodules over the posterior-superior iliac spines and one in the midline. The patient is seated with his back to the camera.

90 to 110. The boy's general condition improved, but the nodules increased slightly in size. The improvement continued for a month, but on Jan. 14th, 1935, slight choreiform movements of the left arm were noticed, lasting for a few days. The temperature rose to 100° F. for two days, and the pulse range to from 100 to 140 for a week, after which it settled to from 90 to 100. On Jan. 24th three large nodules of unusual type were noticed, appearing suddenly and reaching their full size in a few days; they were symmetrically placed over the lower part of the back, one over each posterior superior iliac spine and one in the midline over the lower part of the sacrum (Fig. 2). They were about one inch in diameter and were firmly fixed to the underlying bone, though the skin over them was freely movable. These nodules remained unchanged for about three weeks and then gradually receded, while the other rheumatic nodules became smaller and less numerous.

A series of estimations of the erythrocyte sedimentation-rate was made by Dr. W. W. Payne. On admission it was raised to 44 mm. per hour (Payne's micro method); it fell to 19 on Jan. 9th, but had again risen to 36 on the 14th, at which time the temperature and pulse-rate also were raised and the choreiform movements noticed. It then slowly fell, being 9 on Feb. 4th, after which it rose slowly to reach 21 at the beginning of March.

The special feature of this case is the presence of the three large nodules over the sacrum. Nodules of this type must be exceedingly rare, but it is interesting to note that, in an illustration to a paper by Cheadle in 1889,² three large nodules are depicted in exactly the same situation as those described above. Unfortunately no special reference is made to them in the text. Cheadle states, however, that large nodules are sometimes seen, but that they appear gradually and have an existence of months. The rapidity of formation of the nodules in the present case was striking. It can most readily be understood if one accepts Findlay's view on the presence of oedema. Like all rheumatic nodules, these swellings were painless; this is rather surprising in view of their rapid formation, especially considering their subperiosteal situation, which their fixity to the underlying bone would argue. It is interesting to correlate the time-relationships of the nodules to the other evidences of activity. Their appearance

was preceded by a phase of activity as evidenced by a rise of temperature, pulse-rate, and sedimentation-rate. When the nodules were first seen, however, this activity was already settling down; the temperature was normal, the pulse-rate had settled, and the sedimentation-rate had fallen almost to normal.

I am indebted to Dr. Pearson for permission to publish the case, to Dr. Payne for the estimations of the sedimentation-rate, and to Mr. Martin who took the photographs.

A CASE OF FATAL MENSTRUATION

By E. M. R. FRAZER, M.D. Edin.

ON Jan. 6th, 1935, I was summoned about midday to see a domestic servant who had collapsed when at work for no apparent reason.

Aged 25, she had never had medical attention and was said to have had no illnesses beyond a vague reference to anæmia. Menstruation had begun at 16–17 years of age, and the periods had been regular but scanty. In the summer of 1934 she had no periods for three months, but they subsequently recurred and were regular at monthly intervals till December, 1934. The last had commenced on Dec. 27th, and she had gone about her work as usual, without pain or even discomfort. On the evening of Jan. 5th she felt very tired, but got up and went on with her usual work on the 6th. Just before midday she fainted and her employer sent her to bed.

When I saw her it was at once obvious that she had lost a great deal of blood; she was very white and restless. The temperature was normal, the pulse 110 and thready; there was no pain. The hymen was intact, and after removal of a small vaginal clot the os admitted the tip of one finger, with difficulty. The uterus was small, and there were no signs of pregnancy. Treatment for the moment consisted in packing the vagina, raising the bed foot, injecting pituitrin, and taking general measures against shock. Her hæmoglobin was 40 per cent., but to my later regret I did not do a blood count.

At 8 P.M. the general condition was much as at midday, but there had been further loss of blood about 7 P.M., and she was taken into hospital. Without anaesthesia the cervix was dilated; the uterine mucosa was normal in appearance. The cavity was packed and intravenous saline administered. At 10 A.M. next day she became very restless, and after sudden unconsciousness the jugular veins were much distended. She died about 11 A.M. with signs of cerebral thrombosis.

Post-mortem examination showed a uterus without any pathological changes, and thrombosis of the lateral sinus.

I have not been able to find any similar case on record in this country, but in 1925 van Vugt¹ described one in which a girl of nearly 16 died a week after the beginning of her second period.

After slight injuries, her skin was often covered with blue spots; she suffered from nose-bleeding, and she had been treated for congenital syphilis. There was a deficiency of blood-platelets and coagulation was delayed. The uterus was normal and the liver and spleen not palpable; autopsy was refused. Van Vugt rejects the diagnosis of hæmophilia because, even if its existence in women is admitted, there are too many contrary findings—e.g., the deficiency of platelets. Moreover the stepmother distinctly stated that clots were present. He suggests thrombopenic purpura as a likely cause, although the patient's syphilis should not be forgotten.

In my own case the patient had menstruated for about nine years regularly. She had had no previous illnesses and had always been able to work. The uterus was obviously virgin, and although she had missed three periods last year she had not been incapacitated from work by the fourth—i.e., there had been no abortion. She had had no occasion to seek advice about her "anæmia," which was apparently manifest only in scanty periods and occasional lassitude and breathlessness. Although the percentage of hæmoglobin was low, and no cell count was taken, it is difficult to believe that she could have had any severe anæmia and yet be able to perform her normal work.

Burton-on-Trent.

MEDICAL SOCIETIES

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF OBSTETRICS

A MEETING of this section was held in the Royal College of Physicians on Oct. 18th, Dr. J. S. QUIN presiding.

Carcinoma of the Uterus

Dr. BETHEL SOLOMONS showed three specimens of carcinoma of the uterus, all operated on between August and September, 1935.

CASE 1.—Miss A., aged 52, unmarried, never had trouble with her menstrual periods until four years previous to admission when irregularity might be reasonably expected. For the past year the hæmorrhage had become more severe. She had no other gynaecological trouble. Examination revealed a slightly enlarged uterus, and a diagnosis of carcinoma was made and hysterectomy was done. Dr. Bourke reported on the specimen that the uterine cavity was distended by a cauliflower-like mass; microscopically the growth showed adenomatous polypi which in places suggested a malignant change. The condition was a carcinoma of the body of the uterus of an adenomatous type.

CASE 2.—Mrs. B., aged 57; married 17 years; nullipara. She had had two large ovarian tumours, believed to be

malignant, removed in the country in October, 1932 and 1933. Her only complaint was of a discharge. On examination the uterus was found to be lying back and apparently fixed; the curettings were macroscopically and microscopically malignant. Total hysterectomy revealed a uterus which when freed from adherent small intestine was the size of an eight weeks' pregnancy. The patient did well for eight days and then jumped out of bed when unobserved for a few moments. That evening the wound burst open and about 4 inches of small intestine extruded. The abdomen was closed and drained and she did very well after a stormy convalescence. The report on the specimen was that of a typical adenocarcinoma of the body of the uterus, infiltrating the muscle wall, and proliferating into the cavity of the uterus, and extending down towards the cervix.

CASE 3.—Mrs. C., aged 59; married 32 years; six children. Complained of a yellow discharge (three months), later blood-stained, and pain in the side. There was no loss of weight. Bimanual examination showed a much enlarged boggy body of the uterus with a normal cervix. Total hysterectomy revealed an endocervical carcinoma, the pathological report suggesting that the solid carcinoma in the uterine cavity was probably an extension from the cervix.

Dr. Solomons raised the question whether a diagnostic curettage should be done in suspected carcinoma of the body of the uterus. In his view this

should be avoided unless the diagnosis was doubtful. He commented also on certain points in the technique of total hysterectomy for carcinoma of the body of the uterus. The vagina was plugged with gauze soaked in 3 per cent. picric acid, and if it was known that the uterus was septic or malignant the cervix was sewn up. During the operation no cutting or forked instrument of the volsellum type should be placed in the uterus. Usually clamps placed on the broad ligaments acted as effective tractors, but in Case 2 these would not hold owing to the previous removal of the adnexa. He had sometimes used Bonney's myomectomy clamp to avoid spill. In Case 3 if this endocervical condition had been apparent Wertheim's operation would have been done, but the body of the uterus was much enlarged and corporeal carcinoma seemed to be the correct diagnosis. The enlargement of the body proved to be due to a pyometra. Deep X ray would now be used in this case.

The PRESIDENT said that in Dublin they were very fortunate in having a very low percentage of malignancy in the uterus compared to other centres. He was inclined to agree that the prognosis in the first case described was excellent. As to the second case, two of his own patients had been given prophylactic deep X rays after a total hysterectomy, and had now survived one for three years and the other for four years. Dr. Wilfred Shaw had said that in cases of ovarian malignancy he very seldom found a spread of the disease to the uterus.

Dr. F. S. BOURKE said the first case had not at first looked malignant, but sections revealed a definite adenocarcinoma. The third case was probably a spread from the cervix.

Dr. D. J. CANNON objected on general principles to a curettage in malignant cases. In doubtful cases he had no hesitation in doing a hysterectomy and making a diagnosis afterwards. It was important in operations for so-called functional uterine bleedings to split the uterus and see that carcinoma was not present. If in doubt he did a complete hysterectomy and removed the ovaries from both sides before closing the abdomen. It was only lately that radium was supposed to be indicated in cancer of the body of the uterus.

Dr. G. C. DOCKERAY said that a section from the endometrium in the third case suggested to him a typical squamous carcinoma spreading upwards.

Dr. R. M. CORBET said that it was not possible always to make a diagnosis of carcinoma from a naked-eye specimen, and if a diagnostic curettage was not done, it would be necessary to do a total hysterectomy in every doubtful case.

Dr. BETHEL SOLOMONS, in reply, said that he believed that the small number of cases of carcinoma of the cervix in the Irish Free State was due to good midwifery and the practice of performing trachelorrhaphies and amputations of the cervix. He did not believe in the necessity for deep X ray therapy after hysterectomy for carcinoma of the uterine body, unless there was a suspicion that the whole trouble had not been eradicated. In malignant disease of the ovary there was no need to remove the uterus or the other ovary unless either was involved. He did not agree that diagnostic curettage could be dispensed with, but if the diagnosis of the corporeal carcinoma could be made with certainty, curettage should not be done, as it might cause implantation metastasis. He preferred hysterectomy to radium for cancer of the body unless the woman was suffering from grave constitutional disease.

Removal of Very Large Fibroids

Dr. CANNON showed a very large cervical fibroid which he had removed by abdominal section. The tumour was quite the size of a seven months' pregnancy, and it had a small fundus of the uterus on its upper pole. It was encapsulated, the capsule containing very many large veins. It was found possible to get inside the capsule and enucleate the tumour. Hysterectomy was then performed. Dr. Cannon also showed a large submucous fibroid, removed per vaginam by morcellation because it was sloughing and highly infected.

The PRESIDENT congratulated Dr. Cannon; specimens such as those were usually only seen as post-mortem specimens.

Dr. O'DONEL BROWN said that in a case of a sloughing submucous fibroid he thought there might be danger in removing the fibroid through the abdomen.

Dr. CANNON, in reply, said that the advantage of a small hospital like the one in Kildare to which he was attached was that there was no need to hurry patients away in order to make room for others. The patient from whom the second specimen was taken would certainly not have stood the operation unless she had had some preliminary treatment.

Dr. R. M. CORBET read a communication on

Surgery in the Pregnant

This was based on nine recent patients who had required operation during pregnancy and had all carried to term. The chances of abortion following operation were much less than was popularly believed. He stressed the necessity for early diagnosis and close co-operation between the surgeon and the obstetrician. The percentage of abortion following operation was little higher than the average incidence of abortion, except in operations on the uterus and adnexæ. The maternal mortality of operations undertaken in the early months of pregnancy was no worse than the mortality in the non-pregnant state, but the mortality in the last three months was increased by the difficulties of diagnosis, the technical difficulties of abdominal surgery, and the ease with which peritonitis spread. In his view the best results would be obtained by immediate operation in acute conditions irrespective of the period of pregnancy.

The PRESIDENT said that the view that it was fatal to operate on a pregnant woman died very hard. This and the view that a patient could not travel because she was ill were responsible for a great number of deaths. The danger of appendicitis in women who were approaching full term was peritonitis, and this was due to the fact that it was very hard to get anything like full drainage. He personally thought that a pregnant woman probably had more resistance than a non-pregnant one. Mr. Maunsell had operated in 1925 for cancer of the rectum during pregnancy. Some of the basal anaesthetics should be very satisfactory in these cases, since they had no effect on the foetus.

Dr. T. M. HEALY said that his own experience of surgery in pregnant women had been slight but fortunate. The only fatality he had seen had occurred in the puerperium due to appendicitis. Of six cases of appendicectomy in the early months of pregnancy none had aborted, nor had a case of perineorrhaphy done during pregnancy. He thought there was a great deal of nonsense talked about the danger of anaesthetics to the child.

Dr. R. W. SHAW did not think it mattered much

what anaesthetic was given to a patient provided she was in good condition; if she was not, gas-and-oxygen with some preliminary premedication, preferably morphia, was indicated. It was ridiculous to think that a pregnant woman with a bad tooth could not have it out for fear of an anaesthetic. Gynaecological, even more than surgical, cases required efficient preparation. The shorter the anaesthetic the better for mother and child in cases of Caesarean section. The anaesthetic should not be started until everything was absolutely ready for carrying out the operation, and should be discontinued at the earliest possible moment.

Dr. O'DONEL BROWN mentioned a case in which the corpus luteum had been removed in early pregnancy.

Dr. BETHEL SOLOMONS wished Dr. Corbet had dealt with more cases of late pregnancy. In the early months operation should be done; if appendicitis was diagnosed in the eighth or ninth months operation should be performed, but if there was

any reasonable doubt and it could be postponed with safety until after the birth this would be advisable. Caesarean section should be performed immediately the patient was anaesthetised; too much anaesthetic killed the baby, and he had seen foetal death following delay on the part of the obstetrician.

Dr. CORBET, in reply, said that the paper was not really on surgery in the pregnant but on the attitude of the obstetrician when faced with a surgical complication. He did not think that an anaesthetic had any ill-effect on the baby in utero, but bad effects might be produced in Caesarean section by removing a deeply anaesthetised baby from the uterus. The size of the uterus at term prevented proper drainage, opened up a large area for peritonitis, and by its movements prevented any effective walling off of infection. The real problem was making up one's mind to call in the surgeon. Where the diagnosis of acute appendicitis could not be excluded, he was satisfied that it was safer to submit the patient to operation whatever the period of pregnancy.

REVIEWS AND NOTICES OF BOOKS

Principles and Practice of Medicine

Twelfth edition. By the late Sir WILLIAM OSLER, Bart., M.D., F.R.S. Revision by the late THOMAS McCRAE, M.D., F.R.C.P., Professor of Medicine, Jefferson Medical College, Philadelphia. London and New York: D. Appleton-Century Company, Inc. 1935. Pp. 1196. 30s.

Osler in his life-time made his cherished text-book a classic, and the late Dr. McCrae, taking it over from him, tried always to preserve in it what was characteristic of Osler. In the main he has succeeded. Osler's medicine was essentially bedside medicine, built out of long and rich experience, based on morbid anatomy, and described succinctly with this great man's rare combination of enthusiasm and precision. Dr. McCrae's last preface begs us not to destroy the sweep and the unity of medicine by cultivating it too much in discrete specialties, and warns us against trusting in instruments and laboratory procedures to the neglect of bedside study. That is in the Osler tradition, which the text-book undoubtedly carries on, even though in the newer sections, of which this edition has a goodly number, the authentic Osler style must be lacking. The additions and alterations bring it fairly well abreast of current established opinion. There have been small changes in the general arrangement, but there is still no separate section for the virus diseases; psittacosis and vaccinia appear in the contents as infectious diseases of doubtful or unknown aetiology, although in the text their causation by filtrable viruses is explained. The chief lack in the book is the absence of references, either to the authorities so frequently quoted by name in support or illustration of statements, or to recent comprehensive monographs and papers to which the student may turn when he is specially interested in any disease. Given in small type these would not add too much to the size of the book, which has been kept almost unchanged, in spite of added material and thicker paper, by the use of a slightly smaller, yet bolder and more easily read type. But these are small matters; it is to be hoped that "Osler" will long continue as a favourite on the student's bookshelf, and that the student will not cease to appreciate the principles and practice of a medicine in which the patient is more important than the disease.

Traitement des fractures et luxations des membres

Second edition. By JACQUES LEVEUR, Professeur agrégé à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Bretonneau; and CHARLES GIRON and RAOUL-CHARLES MONOD, Chirurgiens des Hôpitaux de Paris. Paris: Masson et Cie. 1935. Pp. 442. Fr.50.

This text-book on fractures is the outcome of a practical course of instruction which was started by the authors in 1922 in Paris, while they were working under Prof. Pierre Delbet, who contributes a preface. He testifies to the great success of the course, which has since become a regular feature. The book is very well arranged, written, and illustrated. As might be expected, many of Delbet's special methods are incorporated, and in particular it is satisfactory to have a full account of the use of his method of plaster splinting of lower leg fractures. A modification of the method of fixation by the use of moulded plaster-of-Paris splints is described. Pieces of starched muslin are cut to the desired size and soaked in a plaster-of-Paris cream ("bouillie plâtrée"). Excess of plaster is scraped off with the edge of the hand, and the muslin impregnated with the paste is applied around the limb, and moulded on and held in position by bandages. A feature of the book unusual in recent text-books is the attention devoted to operative reduction and fixation of fractures. Though the modern tendency is to use open methods of treatment only as a last resort, it is convenient to find in regard to almost every fracture a description of the operative treatment. Much useful information is contained in the sections devoted to internal fixation, plating, and osteosynthesis. To the surgeon who has to perform these operations, the instruments described and illustrated will be of especial interest. The forceps described as Lambotte's are particularly ingenious. Throughout the work stress is laid on the principles to be kept in mind when each form of fixation is being used.

The non-operative methods of treatment recommended all seem sound and practical; the methods of fixation of the clavicle illustrated on pages 92 and 93 will repay study. In the reduction of dislocations of the shoulder-joint, the method of Kocher is still matised as a "brutal and dangerous procedure,

which ought to be explicitly forbidden." Prof. Delbet's method of reduction by continuous traction followed by slight rotation and pressure over the humeral head is described in detail. The section on first aid is rather too condensed. The volume as a whole is well produced.

Sedgwick's Principles of Sanitary Science and Public Health

Rewritten and enlarged by SAMUEL C. PRESCOTT, Sc.D., Dean of Science, and Head, Department of Biology and Public Health; and MURRAY P. HORWOOD, Ph.D., Associate Professor of Biology and Public Health. Both of the Massachusetts Institute of Technology. London: Macmillan and Co., Ltd. 1935. Pp. 654. 18s.

THIRTY-FOUR years have elapsed since W. T. Sedgwick, then head of the Massachusetts Institute of Technology, published his "Principles of Sanitary Science and Public Health." The book at once made its mark. It displayed an unusual grasp of the principles upon which effective preventive action must necessarily be based, a wealth of skillfully chosen illustrations, strong common sense, and a felicitous power of expression. In America it has long been an authoritative guide to students and health officers, and is recognised as a classic in the literature of public health. In Great Britain, though less well known, it has warm admirers, and no student or practitioner in the field of public health could fail to profit from its stimulating and suggestive teaching. After Sedgwick's death a new edition was long needed, and it has now appeared under the editorship of Dr. Prescott and Dr. Horwood, who worked with Sedgwick first as pupils and later as colleagues in the Massachusetts Institute. They had no enviable task; recent advances in public health theory and practice necessitated extensive revision, and the rewriting of a book so strongly stamped with personality as Sedgwick's "Principles" might well have daunted the most intrepid editor. The work has been done with discretion and, on the whole, with success. In bringing Sedgwick's subject matter up to date the editors wisely decided to make no attempt to emulate his style of writing; they have set out their additions in their own way, and it is a way of concise and lucid exposition, which should appeal to the general as well as to the professional reader.

What is of permanent value in Sedgwick's original chapters is retained. His account of the Broad-street pump cholera outbreak, for instance, the chief features of which should be familiar to all aspirants for the D.P.H., is reproduced, and is supplemented by details of more recent outbreaks of water-borne disease; for the editors have adopted Sedgwick's method of teaching by giving actual examples of how disease has been spread or prevented. The chief stress is laid on environmental hygiene, and those who imagine that Western civilisation is nearing complete success in this field of activity will be quickly undeceived by a study of this volume. Transport developments and rapid changes in social conditions and customs have, indeed, introduced new problems of sanitation. Mosquitoes and other living carriers of disease may now be rapidly conveyed through the air, and as the editors put it: "with the airplane and ocean liner knitting even the most distant and unfrequented areas of the earth closely together, the price of safety against yellow fever and other tropical diseases must be eternal vigilance." The spread of swimming pools, which in the United States increased from 540 in

1913 to over 5000 in 1929, and of holiday camps; the development of air conditioning, cold storage, and refrigeration; and the increase of noise in modern life are only a few of the factors which have added to the problems that a health officer must now be prepared to tackle. On these and other new problems this book affords sound guidance, and though many of its facts are drawn from American experience and have to some extent a special relation to American conditions, the principles they illustrate are of general application. Indeed, the information the book affords on public health work in the United States enhances its value to workers in this country; for in some departments—e.g., the protection of the food-supply and especially milk control—we have much to learn from what is being done on the other side of the Atlantic.

The book may be commended to all who desire up-to-date information on the conditions that threaten the health of modern communities and the means by which such conditions may be successfully attacked.

Preventive Medicine and Hygiene

Sixth edition. By MILTON J. ROSENAU, M.D., Professor of Preventive Medicine and Hygiene, Harvard Medical School. London: D. Appleton-Century Company. 1935. Pp. 1481. 42s.

Rosenau, which has now reached its sixth edition, has become a standard text-book in public health. It has never been allowed to show signs of obsolescence. In preparing the new edition the author, with many of his colleagues, has brought each part up to date, and careful reading shows that very little recent work of interest to public health workers has been missed. New subject matter has been introduced in relation to contraception, maternal mortality, heart disease, diabetes, ringworm, snake poisoning, psittacosis, periodic health examinations, and hospitals. Other parts have been extensively rewritten. As in most American books, the control of communicable disease and modern fields of public health work occupy the earlier pages, environmental hygiene following, but the latter subject receives very full consideration in several sections. An admirable feature is the list—sometimes long—of references at the end of each chapter, which include work done in other countries besides America. Medical officers of health and teachers of public health will find the new edition invaluable.

The Extra Pharmacopœia

Twentieth edition. Vol. II. Published by direction of the Council of the Pharmaceutical Society of Great Britain. London: Pharmaceutical Press and H. K. Lewis and Co., Ltd. 1935. Pp. 889. 22s. 6d.

For fifty years William Martindale, father and son, produced the "Extra Pharmacopœia," aided for a period by Dr. Westcott, and their self-sacrificing labour reduced to order and manageable compass references to outstanding original work and notable advances throughout the whole field of therapeutics. On the death of Mr. W. H. Martindale in April, 1933, the "Extra Pharmacopœia" as a personal production came to an end, and the Pharmaceutical Society decided to take over the responsibility for its continued issue. The revision was entrusted to the Codex Revision Committee, and Mr. C. E. Corfield, editor of the Codex, was appointed editor of Martindale. The "Extra Pharmacopœia" had long been divided

into two volumes, the first devoted mainly to treatment, the second to the analysis and assay of medicinal products. The twentieth edition of the first volume appeared in January, 1933, but the change in policy delayed the issue of the second volume which has only now appeared. The new editor has revised and largely rewritten the matter of this second volume, removing information no longer considered of value to medical practitioners, pharmacists, and analysts and replacing it by more useful accounts and researches into modern substances used in the treatment of disease. One cannot but regret the passing of a classic; in its new guise, however, the "Extra Pharmacopœia" will be found as indispensable as in its old.

Trattato di Anestesia

By A. M. DOGLIOTTI, Doc. di Patol. Chirug., Univers. de Torino. With preface by Prof. O. UFFREDUZZI. Torino: Unione Tipografico-epitrica torinese, 1935. Pp. 552.

This book reflects the greatly increased attention which is now given by continental writers to the theory and practice of general as opposed to local anæsthetics. About 200 pages of this work are given to general, as against about 300 to local measures, and considering the vast number of illustrations which accompany the latter this is giving an importance to general anæsthesia which is remarkable in a non-English volume of this kind. An introductory chapter contains a number of interesting portraits, including one of Henry Hill Hickman. The physiology of pain is lucidly discussed, and then the theory and physiology of the action of narcotic drugs; considerable space is devoted to the use of carbon dioxide. In the illustrations of the practice of inhalation anæsthesia the representation of a Clover's ether inhaler shows one of the old narrow-bore kind now rarely seen in practice in Clover's own country. This instrument is probably little used in Italy either; a regulating inhaler bearing the name "Dogliotti-Giordanego" pictured as well as the well-known Ombrédanne, which has long been in vogue on the continent, take the Clover's place. The most important section of this work for the British reader deals with spinal injection; here he will find described the method devised by Dogliotti himself and so enthusiastically adopted by some French authorities. This is the method of segmental peridural analgesia. Its technique is fully explained and its advantages over the usual endotheal injection are demonstrated. The author does not deny the difficulties associated with its use; he is apparently unaware of the device introduced by his French disciple in order to simplify the technique. The book is well printed and copiously illustrated.

Manual of Human Physiology

Fourth edition. By Sir LEONARD HILL, M.B., LL.D., F.R.S. London: Edward Arnold and Co. 1935. Pp. 470. 6s. 6d.

This little book does not pretend to be an authoritative work, but furnishes an excellent introduction to physiology for those who have received no special training in anatomy or the preliminary sciences. It has been brought sufficiently up to date in revision to continue to fulfil its purpose; the chapter on reproduction is a welcome addition from every point of view. There are now several semi-popular treatments of physiology available, and if asked wherein the present work differs from the rest one would cite its biological approach and its style. The first

fifty pages are devoted to a consideration of life in general, and living organisms are placed in their correct relationship to the rest of the universe. Throughout the book no pains are spared to explain the fundamental scientific basis of the processes described, and if details of the latter are sacrificed on this account the reader may consider himself rather fortunate than otherwise. The style is vivid and the text well stocked with original illustrations and analogies drawn from everyday experience. The book should appeal to a wide range of readers, and will hold their interest.

Quarterly Journal of Medicine

THE October issue (vol. iv., No. 16) contains six papers.

ROBERTSON F. OGILVIE (Edinburgh) has inquired into the contention that in the early stages of obesity there is hyperinsulinæmia with increased sugar tolerance and that this is followed in course of time by hyperinsulinæmia with decreased sugar tolerance. He finds that sugar tolerance diminishes as the duration of obesity increases; the final state may be diabetes. In about a third of 65 obese subjects there was a preliminary phase of increased tolerance. It was observed that deficient ovarian function, premature exhaustion, or destruction of the ovaries produced a definite lowering of sugar tolerance, but whether this occurs in obese subjects only has yet to be determined.

In a study of ten cases of idiopathic steatorrhœa TH. E. HESS THAYSEN (Copenhagen) demonstrates that this derangement of metabolism is characterised by (1) an abnormally high excretion of fat in the faeces; (2) a normal or sometimes slightly increased nitrogen excretion; (3) a flat blood-sugar curve; and (4) a raised rate of basal metabolism. The steatorrhœa, however, is the primary manifestation. Among other problems he considers are the relation of hypovitaminosis B to the hyperchromic anemia and the patches of pigmentation often observed in both tropical and non-tropical sprue and the variations in the possible aetiology of the flat blood-sugar curve frequently associated with these conditions.

MARJORIE GILESPIE (London) has investigated the incidence of hypochlorhydria in asthma with special reference to age-incidence. Low free acidity was found in 51 per cent. of 109 asthmatics, and low total acid in 41 per cent. In allergic subjects there seems to be a tendency for gastric acidity to increase about puberty. Sensitivity as shown by skin tests had no apparent relation to hypochlorhydria, but improvement in acidity in originally hypochlorhydric cases coincided with clinical improvement.

I. HARRIS, E. WYN JONES, and C. N. ALDRED (Liverpool) have examined the pH, lactic acid, and alkali reserve values of the blood in different types of heart disease both under resting conditions and after a standard exercise.

An investigation into the skin reactivity to glycerinated veal broth and its bearing on the specificity of the tuberculin reaction is described by JULES FREUND and P. D'ANCY HART, working in New York. The importance of knowing whether false positive reactions to ordinary doses of tuberculin as a result of sensitivity to the glycerinated veal peptone broth used as a culture medium in preparing old tuberculin was made clear; since if the incidence of the false positive reaction was significant then the use of a control became imperative. It was possible to show that the occurrence of reactions to glycerinated veal broth did not affect the significance of the positive reactions to routine doses of old tuberculin, and that the use of broth controls in routine tuberculin therapy was unnecessary.

RONALD V. CHRISTIE (Montreal) has studied certain types of respiratory neuroses. He is able to show that respiratory tracings taken with an ordinary recording spirometer are of value in the diagnosis and differential diagnosis of certain types of respiratory neuroses and that the incidence of these neuroses is much higher than was generally supposed.

An account is given of the annual meeting of the Association of Physicians held in London last June.

THE LANCET

LONDON: SATURDAY, NOVEMBER 9, 1935

MIND AND SKIN

THE work of the pioneer psychopathologists and psycho-analysts has already influenced medicine to an extent that can be estimated only by those who remember the outlook of pre-war days or are interested enough to study the text-books of those times. With the carrying out of the recommendations of the Curriculum Conference concerning the teaching of psychopathology in our medical schools, practitioners and specialists of the near future will accept as intrinsic parts of the clinical picture such factors as those described in two papers read at the summer meeting of the American Medical Association. These communications illustrate the growing influence of psychology on a form of practice with which it has at first sight little to do. In the first Dr. STOKES¹ gives a surprisingly long list of dermatoses in which a technique of "office analysis" is an important element in recovery. He believes that the type of personality rather than adventitious circumstances influences the cutaneous outbreak; thus "leaders, drivers, tyrants, and hypereffectives in general explode into the cutaneous neurogenous field under stress, excess or frustration." He describes the many signs that betray psychological tension and links these with conditions of vasomotor status and the sweat mechanism, anomalies of which may provide a background for the cutaneous mycoses. Other physiological reactions to stress occur in the sphere of gastro-intestinal function, and in turn induce allergic skin manifestations such as urticaria. But the special lesson STOKES would teach is the recognition and treatment of what he calls the neurogenic factor, and the fifteen years he has devoted to the development of technique have ripened a method of examination and treatment which he finds most helpful—though it needs "an extended and well-digested life experience," in the absence of which psychiatric effort tends to be a skeleton science of mind without flesh of human nature. He excludes from his method pronounced grades of warping of the personality, neurasthenic and psychasthenic collapse, or grades of conduct disorder demanding the use of the full psycho-analytic procedure. His findings reveal on the one hand temperamental or reaction types and on the other those conditions in the environment that seem to act as stimuli in producing symptoms. The distribution of these predisposing and exciting factors seems to vary greatly between one group of skin disorders and another, the "tension frame of mind" occur-

ring, for example, in 41 per cent. of urticaria cases and being absent in rosacea, whilst in the latter chronic worry seems to predominate.

The authors of the second paper² have paid more attention to physical reactions, and, whilst giving validity to the investigation of the "psycho-motor panel," assume the primacy of structure over function by postulating an inborn protoplasmic instability as the condition underlying all the phenomena concerned. This postulate is significant as indicating a fundamental attitude towards the age-long problem of animism versus mechanism, and Dr. STOKES's use of the word *neurogenic* where others would say *psychogenic* possesses the same significance. It is plain that the writers were, like most of us, educated in the mechanistic school but have been driven by clinical needs to study their patients as human personalities with emotional or instinctive drives and reactions; the use of a biochemical terminology does not invalidate that study.

Some apposite comments appear in the discussions that followed these papers. Dr. BECKER noted that medicine is in a state of transition in which internists, endocrinologists, and gastroenterologists are gradually focusing their attention on so-called functional diseases; the work of Dr. STOKES was welcomed as a return to the art of clinical medicine. These papers are, indeed, indicative of a general movement which, whilst progressive, promises an equivalent of what has been lamented as almost a lost advantage—the experience and intuition of the family practitioner who "knew his patient's constitution." We see specialists coming to recognise that behind the processes of disease as revealed by the laboratory there are other processes which, though incapable of being weighed or measured, must yet be earnestly studied as elements of prognosis and treatment if not of diagnosis. It no longer suffices to note that such and such a condition occurs frequently in neurotic or highly strung people; the states thus described are capable of productive investigation, for which modern psychopathology offers a systematised and informed method of approach.

ACUTE PANCREATIC NECROSIS

THE ætiology of acute hæmorrhagic necrosis of the pancreas has been much discussed since the disease was first described by FITZ in 1889. There is general agreement that the basic process is a self-digestion of the pancreas due to activation of the trypsinogen it secretes. Normally this ferment is turned into active trypsin only after the secretion has passed from the gland into the duodenum and come into contact with the enterokinase of the succus entericus; and the reason for its untimely activation in acute pancreatitis is still in doubt. Some authorities find the explanation in infection, which may reach the pancreas either by direct extension (e.g., from a peptic ulcer) or via the blood stream or lymphatics. Blood-borne infection offers the best

² van de Erve, J. M., and Becker, S. W.: Functional Studies in Patients with the Neurodermatoses, Ibid., Oct. 5th, 1935, p. 1103.

explanation of the cases in which pancreatitis complicates mumps or other acute fevers, while lymphatic extension has been held to account for the acknowledged relationship between pancreatic necrosis and disease of the biliary tract. The theory of bile retrojection depends on the fact that acute necrosis has been produced in animals by injecting normal bile into the duct during the period of digestive activity. The possibility is suggested that obstruction at the orifice of the duct, due to spasm of the sphincter of Oddi or impaction of a gall-stone, may lead to a similar state of affairs in human beings; but, as PARRY and MURRAY¹ point out, the anatomical arrangement of the ducts is seldom such as to allow regurgitation. Moreover, though it is common in cases of pancreatic necrosis to find stones in the gall-bladder, it is rare to find one in the common bile-duct; for example, HAWE² states that of 11 patients submitted to operation 7 had stones in the gall-bladder and none had stones in the duct. Another theory is that duodenal contents, containing the normal activator, enterokinase, may gain admission to the duct of Wirsung because of a lesion of the sphincter or the entry of a round-worm. Experiment certainly shows that pancreatic necrosis can be provoked by injecting duodenal contents into the duct. Trauma has sometimes been noted in the history, and the idea has been put forward that this is responsible either by leading to an effusion of blood containing activating substances, or by forcing duodenal contents into the duct. Where no other lesion can be found, vascular disturbance (thrombosis, embolism, or spasm) has been postulated as a cause. The conclusion seems to be that no one hypothesis will cover all cases. As Dr. DOBBS shows in a communication we published last week, the disease is by no means unknown in children, in whom several of the factors mentioned above can be excluded.

Brocq³ has well described the train of events started by the intraglandular conversion of trypsinogen to trypsin. The latter destroys indiscriminately acinar tissue, islets, and blood-vessels, forming a mixture of blood, free ferments, and products of proteolysis, at first confined to the gland but soon escaping into the peritoneal cavity. Absorption of the products of tryptic digestion results in severe intoxication and shock. The lipase produces those white flecks of so-called fat necrosis which are conspicuous at operation. The amylase has no local ill-effects; it is absorbed into the blood stream and appears in the urine. Destruction of insular tissue, if widespread enough, leads to disturbance of carbohydrate metabolism, with hyperglycæmia and glycosuria. At first, however, the typical case presents itself as an "acute upper abdomen" of very sudden onset. Comparing it with other abdominal emergencies TONDEUR⁴ emphasises the rapidity with which the general condition deteriorates in pancreatitis.

The patient, most commonly a woman, is usually fat and middle-aged and often gives a history of previous biliary disease, sometimes of alcoholism. The pain is epigastric, radiating to the back and sometimes to the left shoulder, and quickly grows more intense. There is vomiting and profound shock. Cyanosis is sometimes observed, and there may be bluish discoloration of the abdominal wall, due to altered blood. The abdomen is slightly distended and there is great tenderness in the epigastrium, especially just to the left of the midline. Rigidity is relatively slight, or may be absent; an indefinite mass may be felt in the epigastrium. In the less typical cases it is often impossible to differentiate between acute pancreatic necrosis and other acute intra-abdominal lesions. A high degree of leucocytosis is said to be characteristic, and certain chemical tests may assist diagnosis. According to BERNHARD⁵ about 95 per cent. of cases show a notable increase of diastase in the serum and urine; in about 10 per cent., and in every severe case, there is glycosuria, and in 50 per cent. sugar tolerance is much reduced, a dose of 50 g. of glucose by mouth sufficing to produce glycosuria if this is not already present.

By way of remedy, early laparotomy is usually advised after careful preoperative treatment of shock. The chief argument against expectant treatment is that the diagnosis may be wrong; even if adequate drainage of the pancreas is impossible—as opponents of early operation maintain—and laparotomy possibly harmful, operation at least ensures that perforated peptic ulcers, for example, shall not go untreated because unrecognised. When pancreatitis is in fact revealed some surgeons rest content with the confirmation, but most will insert a drain down to the pancreas. In the presence of biliary disease radical treatment is usually best postponed; but cholecystostomy, with a view to relief of tension, may be done if thought advisable. TONDEUR thinks that aspiration of the gall-bladder is always a wise step if no signs of biliary disease are otherwise detected, for in one of his six cases he obtained purulent bile from an apparently normal gall-bladder. In any event, should the patient recover, radical treatment should not be too long delayed. Recurrence of the pancreatic lesion is not uncommon, and whatever may be the cause of pancreatitis the frequency with which biliary disease is found in these patients justifies the belief that it has something to do with the catastrophe. Another sequel to recovery may be diabetes mellitus; BERNHARD puts the incidence at 10 per cent. of non-fatal cases.

AN INSTRUCTIVE ORGANISM

BOVINE pleuropneumonia does not attack human beings but the micro-organism which causes it is regarded with interest by workers outside purely veterinary medicine. The reason is that it is an example of a virus which is filtrable and yet (unlike other so-called filtrable viruses) capable of growing on simple artificial media. The fact

¹ Parry, J. R., and Murray, K.: *Canad. Med. Assoc. Jour.*, 1934, **xxxi**, 592.

hat it can be cultivated in this way has induced investigators to believe that its nature and mode of reproduction would be discovered relatively easily. That this belief is unjustified is amply proved by the many discordant findings published since 1898 when NOCARD and his colleagues first demonstrated the possibility of growing the virus. Indeed only now, after the lapse of nearly forty years, do we seem to be reaching the truth of the matter.

The story of the growth of our knowledge of this micro-organism deserves to be borne in mind by all who are studying viruses of unknown nature. The agent of pleuropneumonia first became known to us as an ultramicroscopic virus, which, however, was soon shown to be cultivable on artificial media. Probably as the result of successful cultivation investigators turned to the morphological examination of the virus with renewed confidence, and in 1910 two independent series of observations by BORDET and by BORREL and his colleagues showed that it was definitely visible with the microscope. The French workers described a variety of forms—star-shaped or asteroid bodies, coccal forms, and fine branching mycelial filaments—and struck by the importance of the first of these they proposed the name "*Asterococcus mycoides*" for this micro-organism. From now onwards repeated attempts were made to investigate the problem, with widely differing results. There is no need to set out the various findings which have been recorded, but putting aside those which questioned the possibility of seeing the virus, either in stained preparations or by dark-ground illumination, the striking thing has been the diverse modes of reproduction described; there seemed to be almost as many modes of reproduction as there were observers. The work of the last two years has gone a long way to clarify the situation. From a study of this organism and the closely allied one which causes agalactia in sheep and goats, LEDINGHAM¹ has given us a comprehensive picture of their modes of growth and reproduction. He relied mainly on fixed and stained preparations; in particular he studied the structure of colonies growing on solid media by means of impression preparations. He was able to identify almost all the forms seen by previous workers and showed that these were merely different forms of multiplication of a highly pleomorphic organism, which in his opinion has fungal affinities and should no longer be grouped with the viruses. He considers that the micro-organisms of bovine pleuropneumonia and agalactia belong to the family actinomycetaceæ.

Since LEDINGHAM's findings appeared three more papers on the subject have been published. One of these, by MERLING-EISENBERG,² does not support his views, for EISENBERG concludes that the essential forms presented by the organism are elementary bodies and discs from which further elementary bodies arise by a process of budding; he suggests that the branching mycelium described by others is an artefact. The other two papers,

one by TANG, WEI, McWHIRTER, and EDGAR³ the second and more recent by A. W. TURNER,⁴ present observations which are in substantial agreement with those of LEDINGHAM. TURNER relied almost exclusively on the study of fluid cultures by dark-ground illumination and his paper is illustrated by beautiful photomicrographs. In some of these one sees branching mycelium which has every appearance of reality, and TURNER, like LEDINGHAM, concludes that the organism of bovine pleuropneumonia is highly pleomorphic and possesses a number of methods of reproduction. He hesitates to classify it with the actinomycetaceæ, and proposes making a new order—borrelomycetales—in which to place this and the closely allied organism of agalactia. But whatever systematic rank is finally decided on for these two organisms it is clear that they can no longer remain with the filtrable viruses; it is only the fact that one or more of their growth phases is sufficiently small or plastic to pass through filters that has been responsible for this erroneous grouping in the past.

ST. BART.'S MEDICAL COLLEGE

THE PRINCE OF WALES was present on Tuesday at the annual dinner of old students of St. Bartholomew's Hospital which celebrated the opening of the new Medical College in Charterhouse-square for the teaching of pre-clinical subjects. Mr. W. Girling Ball, dean of the college, presided and there were 100 guests, including the Chancellor of London University and the Lord Mayor and Sheriffs, with more than 300 old students. The Prince recalled his visit two years ago and congratulated the dean on what had been accomplished in this time. "We take off our hats to you," he said, "for having got on with the job so quickly"; and speaking as "honorary perpetual student" of the college he welcomed the opportunities of study and research, of which he said, "neither could exist without the other." Mr. Girling Ball remarked that John Abernethy's school had gone on happily for nearly a century within the hospital walls, until the time came for an expansion for which no space could be found. It was in his second year of office that the Merchant Taylors, of which foundation he was a scholar, retired into the country, leaving the Charterhouse free. It had, he said, been a great effort, to which Bart.'s men themselves were contributing more than £55,000. In the near future the scheme was to be completed by the erection of a residential college on the site; "now," he concluded, "we are a real academic institution." The Lord Mayor, in reply to a toast, said that the Corporation of London was watching over the destiny of the school of St. Bartholomew's with a jealous care and regard, and on behalf of London University Lord Macmillan, chairman of the court, spoke of the achievement of an enterprise so full of vision. The work of research would be the great medical mission of the future; to-night, he said, we have seen another milestone passed. Lord Horder paid tribute to the drive, persistence, and indomitable pluck of the dean who had now realised one part of the vision that he had of the integration of medical education in London. Mr. Girling Ball, in reply, said it was the spirit of Abernethy which had always inspired him. On leaving Merchant Taylors to enter Bart.'s he had resolved to do something worthy of both.

ANNOTATIONS

EVOLUTION OF CILIARY ACTION

Forty years ago Sir StClair Thomson and Prof. R. T. Hewlett communicated to the Royal Medical and Chirurgical Society their observations on the fate of micro-organisms in inspired air. Although hourly thousands of bacteria must in ordinary town life pass into the nose, it is rather unusual to find any in the cavities of healthy persons. The vibrissæ of the vestibules filter off most of the bacteria, the remainder being ejected later by the action of the ciliated epithelium. Since then Sir StClair has never ceased to work at the defensive arrangements of the air-passages, and his Semon lecture delivered last week at the invitation of London University summed up what had been discovered about the local means of protection in normal health. It would be easy to conclude either from previous knowledge alone, or under the influence of Sir StClair's persuasive address, that cilia are placed in the respiratory tract primarily to expel bacteria. But this would be only part of the truth, for cilia serve many purposes in the animal economy. Ciliary action depends on protoplasmic flow into and out of a curved tube; filling causes an effective or active stroke, with straightening, while emptying, during the recovery-stroke, is an elastic recoil to the resting position. The action may continue independently of nervous impulses and may survive in a single isolated epithelial cell. The movements are conveyed directly from one cell to its neighbour, and also from cilium to cilium in individual cells. A somewhat similar movement may be observed in simple organisms such as amœbæ; the movements of the protoplasm cause temporary protrusions or pseudopodia. Cilia are permanent projections and represent a specialised mechanism for movement in many primitive aquatic animalculæ. They allow of more rapid progression than is possible with pseudopodia, as may be noticed by watching the activity of paramecium. Cilia thus function as organs of locomotion, but other duties are performed by them. In molluscs and other invertebrates they maintain circulation of water in definite streams, so designed as to collect particles of food, or to serve respiratory purposes. Coming nearer to the subject of the Semon lecture, it is found that in the olfactory organ of some fish, such as eels, circulation of water through the primitive nose depends on ciliary action. The sense of smell is served by an olfactory rosette, with inlet and outlet, but entirely unconnected with the respiratory organs or alimentary canal. Constant circulation of water is required to carry in odours and prevent blockage by mud or other debris.

There can be little doubt that corresponding olfactory necessities call for a similar mechanism in higher animals. Many mammals depend for their existence on the detection of other animals in the neighbourhood. Thus carnivores scent their prey, while herbivorous animals—feeding with their tails to the wind—are warned by their sense of smell of the approach of enemies from behind. Their eyes protect them from attack in front and on the flanks. The eyes, thus occupied, may not be used to pick out suitable food, but the nose serves this purpose, as observed by watching oxen eating grass and avoiding intermingled buttercups. To keep the nose clean and the olfactory sense ready for the perception of fresh and possibly dangerous scents, the various stale odours and any obstructing solid particles must be removed. Odours go into solution

in the nasal mucus before stimulating the olfactory nerve-endings. By means of the cilia this blanket of mucus is perpetually driven back to the nasopharynx, thus allowing new scents to be thrown into solution in fresh mucus, with stimulation of the olfactory nerve-endings. But while as a fact of evolution the nose is primarily an olfactory organ, the mechanism of ciliary movement, with constant backward flow of mucus, automatically removes from the nasal passages all solid particles, such as dust and gives protection against bacterial invasion. Mucus may inhibit bacterial action and phagocytes be ready to envelop them, but if all debris, including bacteria, are rapidly removed from the nose and conveyed through the gullet to the stomach, invasion by organisms is prevented.

The fact that the olfactory sense of man is comparatively feeble naturally diverts attention from the mechanism described, but, when considered in its true light, it opens up the question whether the nose merely looks after its own cleansing, or whether it is in addition a protector of the lower air-passages against bacterial invasion. The nasal fossæ in health are sterile, but from the nasopharynx of a healthy subject a variety of pathogenic micro-organisms may be cultivated. Many bacteria reach the lower air-passages, not only from the nasopharynx, but also drawn in through the open mouth, as during speech. The trachea and bronchi, however, have their own ciliary mechanism for removal of fluid or solid particles, including bacteria; such a mechanism is essential in air-breathing animals. In this connexion Sir StClair drew attention to the healthiness of many persons with permanent tracheostomy openings, emphasising their relative immunity from respiratory disorders. As regards the possibility of further evolutionary changes, it would be difficult to visualise a mechanism more efficient than ciliary action for scavenging immobile cavities such as the nasal fossæ, paranasal sinuses, or middle-ear cleft. The tracheobronchial tree also is efficiently served by cilia, for although its components are capable of varying degrees of closure by muscular action during expiration, yet they must be semi-rigid to prevent excessive or premature closure, with entrapment of air, as may occur in asthma.

A FATAL DISEASE OF SALMON

FURUNCULOSIS is a specific infective disease which has long caused much loss to the salmon and trout fisheries of this country. The departmental committee, appointed in July, 1929, by the Ministry of Agriculture, has just issued its final report,¹ having reached definite conclusions as to the distribution, cause, and means of spread of the disease. Two interim reports have appeared, one of which² contained a recommendation for preventing its further spread which has unfortunately not yet been acted on. The final report contains a summary of all the observations which have been made and of the experimental work done since 1929. Large numbers of fish have been examined for evidences of the disease and the presence of the *Bacillus salmonicida*, and experiments conducted in tanks and ponds have demonstrated means of transmission and the effect of external conditions especially the temperature of the water. The disease has spread considerably of late years; 31 areas of infection are

¹ Edinburgh: H.M. Stationery Office. 2s. 6d.

² THE LANCET, 1933, II., 1135.

known in England and Wales, and 28 in Scotland. The evidence points to extension being due to the importation of fish from infected fresh waters and not to the entrance into rivers of diseased fish from the sea. Infection may take place as the result of contamination of the water or of food; crowding of the fish and a water temperature of 55° to 66° F. are the chief conditions favouring an outbreak. Of interest to pathologists is the occurrence of large numbers of apparently healthy carriers in which the specific organism is localised in the kidney. In these carriers the infection may remain latent for a long time, producing acute disease if the circumstances are suitable. Yearling fish and fry are remarkably resistant to infection. It has been shown that the eggs are not infected internally and can be disinfected with acriflavine without injury. The committee's main recommendations are that the Government departments should have power to inspect fish farms and to prohibit the moving of fish from infected waters, that the occurrence of disease or undue mortality among fish should be notifiable, and that live fresh-water fish should only be imported from abroad under licence. The maintenance of a laboratory for the examination of fish would be essential. A Bill introduced into Parliament in 1934 embodied these recommendations, but did not get a third reading. Considering the heavy loss from furunculosis and its progressive spread it is to be hoped that the Bill will soon be reintroduced and become law.

DIAGNOSIS IN RECTAL HÆMORRHAGE

THE importance of thoroughly investigating a case of rectal hæmorrhage lies not only in the fact that the bleeding may arise from such a serious source as a rectal carcinoma, but also that even when the cause is traced to internal piles, long-continued loss of blood may produce a severe anæmia. E. A. Daniels,¹ of Montreal, points out that this anæmia may seem to be out of proportion to the blood loss. Some patients are apparently incapable of compensating adequately for a steady and long-continued bleeding, while in others the loss of very considerable amounts of blood may produce no grave effects.

Early and excessive loss of blood is not a symptom of any common rectal disease except hæmorrhoids; in carcinoma it occurs rather late, though when it does arise it may be a most troublesome feature. In fissure-in-ano bleeding is occasionally rather sharp, but it occurs only when the fissure is torn open by the act of defecation, and the usual history is that the blood just streaks the motions. The same tearing of the mucous surface may also cause bleeding in cases of stenosis of the anus. Fæcal impaction is another possible, though uncommon, cause of rectal bleeding. The hard, scybalous mass may damage the mucosa of the hæmorrhoidal area, and, owing to the rarity of this cause of bleeding, the findings may be wrongly interpreted, and the hard mass be mistaken for a growth filling the rectum. The symptoms of pain and pressure in the rectum, with bleeding, suggest either a growth or a fissure. Certain diseases of the colon may involve the rectum and cause bleeding from its surface. Such are familial polyposis intestini and colo-proctitis. Sigmoidoscopy will reveal the nature of the lesion and its upward extension beyond the rectum. Acute proctitis may cause such free bleeding as to block the view through the proctoscope. In acute amœbic enterocolitis,

the onset, as Daniels points out, may be sudden, in a previously healthy person, and the bleeding from the ulcerated surfaces may be entirely missed. The colicky, right-sided abdominal pain may simulate appendicitis and even lead to operation in the absence of sigmoidoscopy, which reveals œdema, hyperæmia, and mucopurulent exudation, mixed with blood. Daniels mentions another type of colo-proctitis which occurs as a terminal complication of very severe illness, such as uræmia, typhoid fever, and septicæmia, and also in certain cases of avitaminosis; adenomata and papillomata and tuberculous proctitis are rare causes of bleeding which are easily diagnosed by sigmoidoscopy or proctoscopy. Daniels describes two varieties of internal hæmorrhoids, both usually amenable to cure by injection. In one, the appearance is of a redundant ring of veins, which prolapse into the proctoscope, and may, of course, prolapse below the anal sphincter. The three main hæmorrhoids are situated in the left lateral, right anterior, and right posterior positions of the anal circumference. Owing to the looseness of the attachment of the mucosa, the position of the hæmorrhoids varies with the position in which the patient happens to be examined. The second type of hæmorrhoidal lesion is a vascular ring, bleeding easily when touched and situated at the base of the columns of Morgagni. The treatment advised by Daniels is a submucous injection of 5 per cent. carbolic acid in sweet almond oil. In the second type of lesion the injections are placed into and just above the ring of vascularity. In the commoner type of definite varices the injections are made high up in the submucosa, and the solution distributed down to the base of the hæmorrhoids: 5-10 c.cm. are used at a sitting.

In the diagnosis of the cause of rectal bleeding, the important practical points are: (1) to rule out rectal carcinoma; (2) to determine the presence or absence of an anal fissure, as considerable acute pain may be caused by the passage of the proctoscope for the treatment of piles if the fissure is not first dealt with; (3) having diagnosed the presence of piles, to decide that they are not a complication of some such condition as portal obstruction or pelvic tumour; and also to satisfy oneself that the bleeding is indeed coming from the piles and not from a lesion higher up, such as peptic ulceration. The therapeutic test, of a few injections to cure the piles, followed by a careful watch for further bleeding, may be of value in doubtful cases.

URINARY INFECTIONS

THE symposium on urinary infections in the latest volume of the St. Bartholomew's Hospital Reports (1935) includes an account of the anatomy and physiology of the kidney by Mr. A. M. Boyd, and contributions from a physician, a surgeon, an obstetrician, and a bacteriologist. The result is a clear and useful survey of a problem with which almost every department of medicine is concerned. Dr. Geoffrey Evans supports one of the two main theories of the ætiology of urinary infection when he visualises, in the normal person, a regular or frequent passage of coliform bacilli in the blood stream to the kidneys and their excretion in the urine. He subscribes to the thesis, recently stated afresh by Dr. A. L. Clark,¹ that irregular action of the large gut is responsible for the persistent presence of *B. coli* in the urine of some patients. Mr. J. Beattie, however, discussing urinary infections associated with pregnancy,

¹ Canadian Med. Assoc. Jour., September, 1935, p. 287.

¹ Amer. Jour. Surg., 1935, xxxix, 354.

expresses the belief that the organisms may reach not only the bladder but also the ureters and renal pelves by spread from below, and he brings forward statistical evidence in support of this view. There is now general agreement that, by whatever route the organisms may reach the urinary tract, they do not normally settle there except in the presence of some underlying obstructive lesion. The importance of a thorough investigation of every case of chronic urinary infection has often been stated, but no stronger argument in support of the need of complete urological examinations can be brought forward than the figures collected by Mr. W. Girling Ball. He selected 50 cases of chronic infection of the urinary tract, not in a consecutive series, but chosen either because they had been unsuccessfully treated for a long time without ever having had a complete examination, or else because symptoms of infection were the most prominent feature. Cases of urinary infection with an obvious underlying cause such as an enlarged prostate or a renal calculus were excluded. The 50 cases were thoroughly investigated for some underlying lesion which might be converting them into "carriers," and in no fewer than 38 (76 per cent.) of the cases such a lesion was found. Unilateral infection of the upper urinary passages was found in more than half (62 per cent.) of the cases, of which all but three were associated with a predisposing factor on the side of the infection. The routine investigation consisted first of a searching clinical examination, with a bacteriological analysis of the urine, and then of cystoscopy, ureteric catheterisation, and an X ray of the renal tracts (including pyelography). It might be argued that it is not justifiable to submit every patient with a mild chronic infection to so exhaustive an examination; but it is a striking fact that of the 50 cases reported by Mr. Girling Ball, 33 (66 per cent.) were completely cured by the treatment, where necessary surgical, of the discovered lesions. When it is remembered that these cases were selected for their chronicity and on account of the absence of any obvious predisposing causes, these figures represent a remarkable achievement in the treatment of an obstinate infection. Dr. Clark has suggested¹ that if patients with infected urines were placed on the ketogenic diet before such investigations as ureteric catheterisation and cystoscopy were performed, unpleasant complications such as catheter fever might be avoided, and this suggestion is well worth consideration.

The uses and limitations of urinary antiseptics were discussed at the recent B.M.A. meeting in Melbourne (see p. 1076). Dr. L. P. Garrod's contribution to the Bart.'s symposium consists of a survey of the various urinary antiseptics in common use, and a comparison of the clinical and laboratory claims made on their behalf with the result of a test devised to measure their true antiseptic value by a study of the bactericidal power of the urine excreted by patients taking the drugs. Of the urinary antiseptics tested, hexamine alone produced a truly bactericidal urine, such as is excreted by patients on the ketogenic diet. Yet, as Dr. Garrod notes, though some forty years have elapsed since hexamine was introduced into medicine, "misunderstanding and misuse have given it a chequered career." Hexamine by itself is not bactericidal and only when, in an acid medium, it decomposes to give off formaldehyde does it exert any antiseptic effect. Though acid sodium phosphate is widely used with hexamine to increase the urinary acidity, the resulting acidity is rarely measured, and in fact the necessary degree is much more readily

attained by the use of ammonium chloride. The control of urinary infections by medical treatment demands a careful supervision, not only of the patient, but of his urine. It is as illogical to hope for any effect to follow the administration of hexamine without ensuring that the urine becomes really acid, as it is to expect an acute urinary infection to respond to treatment with alkalis until the urine becomes alkaline.

UNRESTRICTED DIET FOR DIABETIC CHILDREN

SOME four years ago Stolte of Breslau recommended that diabetic children should eat whatever they like; and this recommendation is now supported by Prof. A. Lichtenstein¹ of Stockholm. Insulin, he feels, has been given too timidly, and even to-day its use is considered secondary to strict dieting, so that the child suffers all the hardships, physical and mental, of being rationed. In Friderichsen's words "from the psychological point of view, it is better to let the dosage of insulin be determined by the food than vice versa," and during the past two years Lichtenstein has let a score of diabetic children in his hospital and private practice enjoy a free diet. This is free both in kind and in quantity and the dosage of insulin is regulated in such a way that the general health is good, the gain of weight normal, and the urine is free from ketone bodies—glycosuria being permitted so long as weight increases satisfactorily. The ages of the patients ranged from 2½ to 16 years, and most of them were admitted to hospital so as to be under close supervision on passing from a restricted to an unrestricted diet. The transition proved remarkably easy, and the joy of patients and parents on the removal of all restrictions had to be seen to be believed; indeed the encouragement seemed to have a directly beneficial effect on the course of the disease. At first the children showed a voracious carbohydrate hunger which soon passed off, leaving them with an only somewhat higher carbohydrate consumption than when rationing was maintained. Thus, a 7-year-old boy who had been rationed to about 110 grammes of carbohydrate put away about 300 g. per day when allowed to eat what he liked, but later spontaneously reduced this quantity to about 200 g. So far from any ill-effects being observed, the sweeping-away of all dietetic restrictions seemed to be uniformly beneficial, to judge by an improved gain of weight and comparative freedom from intercurrent infections. The increased gain of weight probably depended not only on the increased supply of carbohydrates, but also on the total rise in the calories, children between the ages of 9 and 12 consuming 50–70 calories per kg. of body-weight. The dosage of insulin did not have to be raised correspondingly; there were cases in which it was not raised at all and some indeed in which it was actually lowered, though the carbohydrate intake had been doubled. Similarly, the excretion of sugar in the urine was surprisingly small. The frequency of the injections of insulin had to be increased from two to three a day, but on the credit side of the balance the risk of insulin overdose seemed to be diminished.

The cases in which this therapeutic revolution was accomplished were by no means slight and mild; all the patients had been in coma or had threatened coma once or oftener. Prof. Lichtenstein is accordingly persuaded of the great merits of the unrestricted diet; but he has yet to prove its real advantage over the properly regulated intake of food. Admittedly insulin has not been used with sufficient boldness

¹ Nord. med. tidskr., August 31st, 1935, p. 1329.

and every diabetic child should be given enough food and enough insulin to enable him to live a normal life, feel perfectly well, and develop normally. But if this aim can be fulfilled is there anything to be gained by giving an excess of carbohydrate? The free diet must mean occasional big rises in blood-sugar and increased glycosuria, which are theoretically objectionable and certainly (one would suppose) should not be risked within a couple of years of the onset of diabetes. The disadvantage of three daily injections is also obvious, and the regulation of dosage cannot be very easy.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

THE first decade of the London School of Hygiene and Tropical Medicine is briefly surveyed in the annual report of the board of management to the court of governors. Since its establishment in 1924 an imposing building, complete with modern laboratory and scientific equipment, has been erected; post-graduate courses of study in bacteriology and immunology, biochemistry, epidemiology and vital statistics, public health, and tropical medicine and hygiene have been established and developed under the guidance of distinguished teachers; and the separate institutions for the study of tropical medicine and tropical hygiene, founded respectively by Patrick Manson and Ronald Ross, have been incorporated in the school. The report of the dean, Prof. W. W. Jameson, for the year ended July, 1935, records the close and happy relations maintained with other scientific and professional organisations and the practical value to the staff of this association. Full advantage has been taken during the year of the policy of encouraging members of the staff to visit tropical and sub-tropical countries for the purpose of conducting special investigations or studying local problems. For example, Sir Malcolm Watson has visited Central and East Africa; Dr. Wigglesworth, Malaya, the Dutch East Indies, and Ceylon; Mr. J. J. C. Buckley, D.Sc., Assam; Dr. R. Mellanby, Uganda; Prof. P. A. Buxton, Macedonia; and Mr. H. H. Clay, India. During the year 179 students enrolled in one of the regular courses of instruction in addition to a considerable number who attended for short periods of more specialised study. The work on the isolation of a chemical substance of high immunological value from *B. aertrycke* which is being conducted by Prof. W. W. C. Topley, F.R.S., and Prof. H. Raistrick, F.R.S., has proceeded most successfully during the year. The grant which Imperial Chemical Industries Ltd. made towards the cost of this investigation came to an end on Sept. 30th, 1935, and some anxiety is felt about the money necessary to continue what is regarded as one of the most important and promising researches of recent years. Prof. G. S. Wilson has completed a very thorough study of the various methods of assessing the bacterial content of milk and his report, which should be of great practical value, is about to be published. The investigation on the lethal effects of oil on mosquito larvae is now in progress in Prof. Buxton's department; the cost of this work is being borne by three large petroleum companies. Attention is drawn by Prof. M. Greenwood, F.R.S., to the closer liaison between the division of epidemiology and vital statistics and official government departments; an inevitable result is that still more time has to be devoted by the personnel of the division to work which will either never appear in print at all, or, if published, will not be published over the names of the authors. Work of this kind is however regarded

as an essential duty, since the division enjoys the confidence of various public authorities who rely upon the staff to give them frank advice on various statistical and epidemiological matters, knowing that the confidence will be respected.

THE AIR-SWALLOWING INFANT

THOSE who live on fluid alone are almost bound to gulp in air with it, and Lereboullet and his colleagues¹ think air-swallowing a common source of trouble in infancy. Vomiting from this cause may begin, they point out, in the earliest days of life, being seen more often probably in breast-fed than in bottle-fed babies. It may be explosive or merely regurgitant, and the milk as returned may be curdled or not, according to how long it has been in the stomach. The child's appetite is likely to be excessive, but after three minutes' greedy feeding no more food is taken until relief has been obtained by an eructative vomit. In the early stages of the disturbance the general state remains good; the stools are normal and weight may be gained despite the vomiting. If the right diagnosis is made all will be well; but only too often the vomiting is attributed to dietetic error, and the baby is made to try a series of foods and formulæ, culminating perhaps in a true breakdown in digestion, with the "diarrhoea and vomiting" syndrome. Since all babies swallow air with their milk it may well be asked why they do not all suffer in consequence. Lereboullet's answer is that some swallow more and some less, and it is the greedy baby who, rapidly distending his stomach, is most likely to vomit. The degree and speed of evacuation of the air both by the upper and lower openings of the stomach also varies greatly, and the position in which the child is placed after feeding makes a difference. As part of treatment the French authors recommend that after an attempt has been made to "get up the wind" by holding the infant in the vertical position for the usual period, it should then be placed on its left side for a quarter of an hour, after which it remains on the right side till the next feed. They also advise the use of thickened feeds, or even the introduction of the milk through an œsophageal tube. For the breast-fed baby, to whom this programme is inapplicable, they suggest a teaspoonful of condensed milk or of a thick farinaceous paste immediately before feeds. Possibly, however, a drink of water would be equally effective; and there is another measure, also favoured in this country, which gets only rather grudging notice—namely, a small dose of a sedative (such as chloral) just before the feeds. In practice this problem is of real importance, for weaning is far too often carried out merely because of excessive air-swallowing by a baby who is otherwise thriving. Robert Hutchison teaches that chronic vomiting can be ignored if an infant is gaining weight, and this rule applies especially to the kind of case under discussion.

THE TEACHING OF ANÆSTHETICS

A LIVELY discussion was provoked by the presidential address of Dr. H. A. Richards to the section of anaesthetics of the Royal Society of Medicine on Nov. 1st. The points which aroused most interest centred round the teaching of anaesthetics to the student. The difficulties which confront the teacher of this subject are perhaps more formidable than those which the teacher of any other clinical subject must

¹ Lereboullet, P., Lelong, M., and Aimé, P.: Presse méd., Oct. 5th, 1935, p. 1541.

face. It is a question of what Dr. Richards aptly called the anaesthetist's "divided loyalty." If he does his best for the student he cannot at the same time do his best for the surgeon and for the patient. At a given operation it may be desirable to employ an elaborate technique and a complicated apparatus. What use is this experience to the student who in a year or two will be engaged in general practice? He is not going to possess the apparatus or have any suitable opportunity of exercising or advancing his slight acquaintance with the technique. So far as he is concerned his need is to be given competence to handle simple methods efficiently and safely. Moreover, the greater his freedom to work without supervision the better for him—but often the worse for the surgeon, who may have to wrestle with the consequences of an insufficient narcosis, from which the patient may also suffer indirectly. Some anaesthetists untie the Gordian knot by cutting it. They say in effect "I do my best for the patient and for the surgeon. The result is I rarely employ methods which can be used by the general practitioner; and there is no harm in this, for the sooner all anaesthetics are given by specialists the better, and then the student will not need to learn the technique unless he wants to take up the specialty." It was clear from the discussion which followed that the teaching anaesthetists disagree even on so fundamental a question as the relative positions of ether and chloroform as general anaesthetics. Some teachers, like Dr. H. P. Fairlie, would rule out the latter altogether; others, whose views were well expressed by Dr. Ashley Daly, argue that in general practice it is practically certain that sooner or later chloroform will be handled and therefore the student must be made familiar with the proper way of using it if its dangers are to be minimised. Dr. H. P. Crampton further complicated the issue by advancing the opinion that chloroform should be employed only by the specialist, in whose hands alone it is reasonably safe. Anaesthetics seems to be in a transition stage; some of its experienced practitioners achieve such excellent results using the same simple drugs and apparatus for all cases that it is difficult to convince them that these could be improved. On the other hand, the modern member of an operating team has an armamentarium so varied that he alters his technique for every type of case and naturally doubts the wisdom of attempting to teach it except to an aspiring specialist. It will be long, however, before the custom of mutual aid in anaesthetics, especially for minor operations, dies out among practitioners, especially in country districts, and in the public interest some way will have to be found to procure the preliminary experience necessary for such work.

VAGINITIS

VAGINAL discharges have a name for being intractable; but a fair proportion of successes may be expected from the more discriminating use of remedies which is now becoming possible. This improvement in therapeutics depends chiefly on greater accuracy in diagnosis and better knowledge of causation. For example, Cruickshank and Sharman,¹ and others, have lately demonstrated the profound influence which the ovarian follicular hormone exerts on the vaginal epithelium, and it is now recognised that the susceptibility of the mucosa to infection varies according to the physiological changes induced by

birth, puberty, marriage, childbirth, and the menopause. One result of these observations has been the attempt to utilise the ovarian follicular hormone (œstrin) in the treatment of vaginal infections, especially in the gonococcal vulvovaginitis of children, as described not long ago in our columns by Nabarro and Signy.² Reviewing the problem of diagnosis and treatment as a whole, Hubert Jacobs³ of Melbourne emphasises the importance of the patient's position during investigation and takes the view that the dorsal position is the most favourable for thorough examination and the taking of specimens. His statement that gonococcal vaginitis is extremely rare in women is in accordance with accepted ideas; on the other hand, King and Mascall⁴ have lately offered evidence that the gonococcus may persist for considerable periods in the adult vaginal fornices. In referring to gonococcal infections, Jacobs rightly demands a high standard in tests for cure; it should be pointed out, however, that reliance on examinations which do not include cultural and serological tests tends to leave a dangerous margin of error.

Vaginitis due to the flagellate *Trichomonas vaginalis* is very widespread and its diagnosis is easily confirmed by a simple microscopical test; but unfortunately many who treat these infections do not appear to realise this. Though the common practice of douching with the ordinary antiseptics is usually ineffective, there are methods of treatment which give good results, and elsewhere in our present issue Dr. Biskind describes a promising addition to those already available. Jacobs notes the occasional association of trichomonas infections and those due to the gonococcus; and recent experience in this country suggests that improved methods of gonococcal culture may prove this association to be common. Vaginal infections due to a fungus of the monilia group, termed variously aphthous vulvitis, mycotic vaginitis, or vaginal thrush, are relatively rare, but are readily recognised clinically and with the microscope. The response to treatment is usually satisfactory, but their frequent association with glycosuria should not be forgotten.

ON Thursday, Nov. 14th, at the University of Durham College of Medicine, Newcastle-upon-Tyne, Prof. Ferdinand Sauerbruch, director of the Chirurgisch Poliklinik at Berlin, will deliver the annual address to the medical society of the University on the position of modern surgery in the light of history. On Friday he will address the Newcastle and Northern Counties Medical Society at 4.15 P.M., in the Royal Victoria Infirmary, on the development of thoracic surgery.

ON Thursday, Nov. 21st, at 4 P.M., Mr. W. Sampson Handley will deliver the William Mitchell Banks lecture at the medical school of the University of Liverpool. He will speak on the prevention of cancer.

ON Tuesday, Nov. 19th, at 5 P.M., Sir Walter Langdon-Brown will deliver the fifth Victor Horsley memorial lecture at University College Hospital medical school. He will speak on the integration of the endocrine system, and Sir Gowland Hopkins, P.R.S., will take the chair. Medical practitioners will be admitted to the lecture on presentation of their visiting cards.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXVI.—PROGNOSIS IN MIDDLE-EAR SUPPURATION

MIDDLE-EAR suppuration is met with at all periods of life from earliest infancy to extreme old age. It is responsible not only for an enormous amount of discomfort and suffering, but also for serious disabilities and, in many cases, gives rise to conditions whereby life itself is endangered. It is thus foolish to regard middle-ear suppuration as a trivial ailment, as was not unusual some years ago, and it is fortunate that in recent years a careful study of the aetiology and the natural course of the disease, together with the varieties of treatment and the alterations they have been found to effect, have improved the prognosis immensely in all directions.

In the vast majority of cases the infection reaches the middle ear via the Eustachian tube, although in sucklings there is reason to believe that the infection is more often blood-borne than in adults. The spread of infection from the pharynx or nasopharynx is usually the sequela of a cold or some more severe infection such as influenza or one of the specific fevers. Any unhealthy condition of the nasopharynx, for example adenoids, predisposes to the occurrence, and it has been known to follow plugging of the nasopharynx, or even of the nose after operations, or the entrance of blood or discharges into the Eustachian tube. The entrance of unclean water when diving or swimming under water is also a source of middle-ear suppuration.

Middle-ear suppuration occurs very readily in sucklings and infants as the Eustachian tube is comparatively short, wide, and straight, and in the early months of life the mucous membranes are very prone to infection. That the pharynx is often the site of infection is evident from the frequent association of an enlarged cervical gland and middle-ear suppuration. It is important that small infants should be kept from those suffering from the common cold, as a cold in the head, usually a trivial affair in adults, may be a serious matter in infancy. It would be a counsel of perfection to suggest that all young children suffering from colds should be kept in bed for a day or two, but if this were the rule, not only would the spread of infection be prevented, but the occurrence of middle-ear suppuration would be diminished.

When infection reaches the middle ear and suppuration occurs, the products of inflammation accumulate in the first place in the lower part of the tympanic cavity, the atrium. It will be remembered that the tympanic cavity may be considered as consisting of two parts, the lower or atrium, and the upper or attic. The atrium is a simple four-sided cavity lined by a thin adherent mucosa with very little connective tissue; the Eustachian tube opens into its anterior wall and its external wall is the tympanic membrane or ear-drum. The attic, on the other hand, is a complicated cavity, containing the ossicles and their numerous ligamentous connexions. These are covered over by folds or curtains of mucous membrane which further subdivide the cavity into compartments and which hang down and help to shut off this cavity from the atrium. The posterior part of the attic is directly continuous through the aditus into the

membrane, as in the atrium, but is formed by thick bony squama.

When the middle ear becomes infected, the products of suppuration accumulate in the atrium, Eustachian tube being closed by the congestion of the mucosa and the attic cavity mainly shut off by swelling of the mucous membranous folds of Tröltsch. As the pressure increases, the wall which offers the least resistance—namely, the external wall which is formed by the tympanic membrane—begins to show signs of the trouble behind it, and the subjective symptoms become correspondingly increased. These symptoms consist chiefly of earache and fever, whilst noise in the head are often complained of and deafness becomes noticeable. The pain may be sudden and sharp and often reaches a point at which it is almost unbearable, making sleep impossible. The temperature is raised, and, in children, is often 102° F. and more. The general condition deteriorates rapidly owing to fever, pain, and sleeplessness. The ear-drum shows signs of inflammation and is usually dark in appearance. The usual landmarks are lost in general swelling, which is most marked posteriorly and appears to cover the handle of the malleus. A definite bulge of the membrane is seen, most often in the postero-superior quadrant. The light reflex is lost. It should be noted that in very young infants this loss of light reflex may be the only sign in some cases, and also that bulging of a normal membrane may occur when an infant cries, so that too much reliance should not be placed on this appearance in the very young. In the average case the accumulation of the products of inflammation behind the drum causes it to rupture, and this may occur within 24 hours after the appearance of the initial earache or may be delayed for some days. If the drum is seen before it has ruptured and is bulging it should be incised. It is important that the incision should be carried upwards through the posterior fold out towards the meatal wall. This will ensure free drainage from the upper compartment and help to prevent the further extension of inflammation. When the drum bursts or is incised there is usually immediate cessation of pain and a fall in temperature. If the pain stops quickly it is a favourable sign; it probably indicates that the suppuration is confined to the atrium as pain due to attic suppuration is much less likely to be relieved at once.

With rupture of the drum the atrium empties its contents into the external auditory meatus. If free drainage is established resolution of inflammation should occur and the prognosis should be favourable unless adverse factors are at work, such as a very virulent infecting organism or some lack of resistance on the part of the patient. Old people seem to have a peculiarly low resistance to aural infections.

AFTER-TREATMENT

The object of after-treatment is to facilitate discharge from the tympanic cavity through perforation and to ensure that it is removed from the external auditory meatus and does not lie in contact against the drum membrane. Efficient after-treatment can therefore influence the prognosis very materially. Many methods of after-treatment have been adopted—an effective one is to place a gauze w

mopping or sucking out of discharge; but I prefer the use of dry insufflations of powder, such as a 1 per cent. iodine in boric powder, or Dimol, blown into the meatus each day after a thorough cleansing. The mass of dry powder against the drum seems to attract the discharge through the perforation very efficiently and it is quite extraordinary how much discharge the powder can absorb. The powder can be changed once or twice daily. As the discharge diminishes, the congestion of the Eustachian tube subsides and this canal provides a supplementary drain for the escape of fluid from the middle ear. The prognosis with regard to ultimate recovery is good and the drum heals without an apparent scar. The outlook as regards the hearing is difficult to foretell, but is usually good, except in some of those cases in which healing of the drum is, for some reason, unduly delayed.

COMPLICATIONS

If the discharge persists for more than three weeks one may assume that the inflammation is no longer limited but has spread to the attic and, in all probability, to the mastoid antrum as well. It may be that the infection of the attic was a primary one, as in some cases the infection seems to pass through the atrium and infect the attic or even the mastoid antrum from the beginning. Be that as it may, the prognosis is now altered for the worse. We have seen that the lining mucosa of the attic hangs in folds across the cavity and this vascular connective tissue forms a suitable medium for the growth of organisms. Moreover, the opening of the aditus is comparatively large and any pus which is formed may take the line of least resistance and pass backwards into the mastoid antrum. This involvement of the mastoid occurs in about 25 per cent. of all cases of acute middle-ear suppuration and as this is dangerous, not only on account of the likelihood of chronic suppuration after the acute stage is passed, with damage to the hearing, it is most important that it should be recognised at the first possible moment. It will be remembered that, developmentally, the mastoid antrum is merely a backward extension from the upper part of the tympanic cavity and is present before any mastoid process or cells appear. It is not unusual for some tenderness over the antrum to be present in moderately severe cases of middle-ear suppuration and this usually disappears if the drainage from the middle ear is freely provided for, but if it persists or extends the implication is that the mastoid cells themselves have become infected, the prognosis is not so good, and the mastoid will require opening. Again, reappearance of the discharge after it has stopped or nearly stopped, or the persistence of a very profuse discharge with pulsation, indicates the likelihood of mastoid involvement, as does the continuance or recurrence of pain. The most characteristic sign is a sagging of the postero-superior wall in the deepest part of the meatus.

It would be beyond the scope of this short article to consider the further signs and symptoms of acute mastoiditis and it will suffice to say that, should the surgeon decide that the mastoid is involved, nothing is gained by delaying operation unduly. If the mastoid has to be opened, naturally the time of recovery is lengthened, but the prognosis with regard to ultimate repair of the middle-ear suppuration and the restoration of function should not be adversely affected.

CHRONIC SUPPURATION

It is a common experience that a certain number of cases of acute middle-ear suppuration become chronic,

and it is sometimes difficult to say why this should be so. Neglect of treatment, constant reinfection by repeated colds, and the presence of adenoids are factors which favour the occurrence, whilst cases following measles and scarlet fever often fail to clear up quickly, as do some in which influenza is the source of infection.

It will be well to consider to what extent purely conservative measures are likely to be successful in the ordinary case of chronic middle-ear suppuration, and in what percentage of cases the prognosis is a good one. If after removal of adenoids and the adoption of some general cleansing measures for the ear suppuration still continues, a careful course of conservative treatment at the hands of an otologist should result in about 50 per cent. of ears becoming dry. There are many different methods of treatment but the one which gives the most satisfactory results is a modification of the dry method that is advocated for acute cases. In the chronic case it is advisable to clean the ear thoroughly, not only the external auditory meatus, but the middle ear also by irrigating it through an intratympanic cannula; the ear is then inflated by Valsalva's method to clear the middle ear of fluid, the meatus is again dried, and iodised boric powder is then blown in. In some cases polypi or small granulations may first have to be removed, particularly if the perforation is an attic one, and in these cases the prognosis is not so good, though many heal up quite satisfactorily. Some surgeons advocate the use of zinc ionisation, but I have not been able to satisfy myself that it yields superior results to the above method, and the cases in which it seems most successful—namely, those with large central perforations—are the very ones which respond most quickly to the more simple methods. If healing does not occur in two to three months it is probable that the suppuration is being kept up by some necrosis of the structures in the attic or in the mastoid, and a successful result is not likely to be obtained without a mastoid operation. It may be that a certain proportion of cases are doomed to this from the beginning and many of the most resistant ones may have a definite anatomical basis, as Arthur Cheate suggested many years ago. He found from examination of a large series of temporal bones that in 20 per cent. of all people the mastoid process remains of the acellular type, and that when the middle-ear tract is infected under these conditions and complete resolution does not take place or other complications occur, the disease passes into a chronic stage which may continue indefinitely and be associated with more or less destruction of the tympanic structures and the formation of polypoid granulations and cholesteatoma. In these cases a mastoid operation is necessary if the cure of the middle-ear suppuration is to be effected.

WALTER HOWARTH, F.R.C.S.,

Surgeon to the Ear and Throat Department,
St. Thomas's Hospital.

WEST SUFFOLK GENERAL HOSPITAL.—This institution at Bury St. Edmunds is embarking on an extension which will cost at least £25,000. At present there is only one ward for women and some of them have to be accommodated in the children's ward and in a small auxiliary ward. It is not always possible to separate the surgical and medical cases. The provision of a new children's ward is necessary and the present one can then be converted into a second ward for women. A private ward for paying patients is another urgent requirement.

SPECIAL ARTICLES

BRITISH MEDICAL ASSOCIATION

MEETING IN MELBOURNE

SECTION OF DERMATOLOGY

Dr. S. WATSON SMITH (Bournemouth) presided at a meeting of this section when Dr. HERMAN LAWRENCE read a paper on the incidence of

Skin Diseases in Australia

He compared the order of the commoner skin diseases in England, America, and Australia, and explained the reasons for these variations. Eczema, dermatitis, and seborrhœa occupied first place in all three countries. In England the second place was taken by ringworm, pediculosis, and scabies, whereas these hardly came into the picture at all in Australia owing to the difference in social conditions. The climate of Australia favoured an out-of-door life; the poorer classes lived in separate dwellings and had greater conveniences for personal cleanliness. In Australia the second place was filled by a group consisting of rodent ulcers, keratoses, and epitheliomata. This was due to two factors: (1) the increased amount of sunlight, and (2) the relatively low humidity. Adelaide had double the amount of sunlight and nearly half the humidity of London. In central Australia the average amount of sunlight was over 3000 hours per year, and the humidity under 30 per cent. The temperature was also much higher, rising to over 115° F. in the shade. The amount of ultra-violet light reaching the skin was therefore very great. Many of the patients had marked keratoses solares of the face, hands, ears, and forearms, without any signs of malignancy developing. After a history of the patient picking at the lesion, or perhaps of the application of CO₂ snow, one of the lesions would rapidly enlarge, and a frankly malignant epithelioma would develop. Italians and aborigines were almost free from these troubles. The bathless and sun-bathing cult, whilst lessening the likelihood of parasitic disease and skin tuberculosis, was a real menace in Australia as the cause of cancerous or precancerous lesions. Dr. Lawrence then described some rarer skin diseases of interest:—

Favus.—In 1917 a plague of millions of mice appeared in Queensland and travelled 1500 miles into South Australia. Some of the mice developed skin diseases which they passed on to human contacts. Many of the lesions were due to a parasite of the ringworm order, but the most troublesome ones from the point of view of treatment were due to an achorion—the *Achorion quinckeanum*. X ray therapy was of great value, especially in lessening the pain and shortening the time required for cure. Since 1917 there had been several minor troubles of this nature, and it was recognised that cases of favus, both in human beings and in mice, were more or less continuously present.

Dermanissus avium et gallinæ.—During the past 30 years Dr. Lawrence had many times found the dermanissus to be a cause of pruritus in patients who had nothing to do with poultry yards, and in several cases he had actually traced the parasite to abandoned birds' nests near windows. He suggested

mention of it. It was often difficult to cause of the pruritus to these parasites, as nocturnal in their habits, generally hiding daytime. The nests of starlings, pigeons, sparrows were most likely to harbour them.

"Collision value."—When gamma rays in direction collided with beta rays from the same direction, their combined action was termed by Dr. Lawrence "collision value." He mentioned this action in the treatment of keratoses and ulcers. The radium was held in metal holders and earthed. A high-frequency current was applied, with the patient standing on an insulating mat. In this way there was a veritable bombardment of rays and particles up to about 1 cm. distance. The treatment was rapid and effective, but care had to be exercised lest the absorbed beta particles caused necrosis of the tissues.

Dr. W. UPTON (Adelaide) in analysing 3000 cases had obtained figures similar to those of Dr. Lawrence but in his series scabies and ringworm were common. One case in eight was in the keratinized rodent ulcer—epithelioma group. Many were elderly women leading an outdoor life and using no cosmetics. He had seen 5 cases (in 25 years) of erythematous developing after severe grain itch was a common disease in South Australia. Lip cancer occurred in non-smokers after long sunburn and cracking of the lips.

Dr. F. H. MAKIN (Adelaide) gave an analysis of 3000 patients treated at a cancer clinic. There were 1774 skin lesions, hyperkeratoses, and 456 squamous-celled carcinoma of the skin. Rodent ulcers 887—many patients had multiple lesions. In addition, there were 188 cases of carcinoma. Nearly all were proved microscopically. Multiple keratoses were best treated by curettage. Ringworm of the feet and dhobie itch were common in South Australia, and cases of scabies seemed to be increasing.

Dr. J. M. O'DONNELL (Perth) also found hyperkeratosis a common complaint, particularly in the gold-fields. Psoriasis, ringworm of the scalp, and dhobie itch were common, and scabies was increasing. An epidemic of grain itch had occurred among wharf labourers.

Dr. J. WITTON FLYNN (Sydney) had found ringworm often enough to justify its inclusion among the 15 most common skin diseases.

Dr. J. H. KELLEY (Melbourne) had also found that sunburn predisposed to lupus erythematosus. Syphilitic diseases of the skin were now quite rare.

The PRESIDENT agreed that the low humidity and the increased amount of ultra-violet light in Australia were factors predisposing to skin cancer. Favus was unknown in England but common in South Australia. Dhobie itch was frequently found in boys' schools.

Dr. J. IVAN CONNOR (Melbourne) read a paper on the treatment of

Staphylococcal Infections of the Skin

Numerous lesions, he said, were produced by staphylococci, but these tended to remain true to type, that there were probably many different strains of the organism. Cases of syphilis rarely developed.

coccal lesions suggested that none of them could be relied on to promote recovery in obstinate cases. For this reason research work had been done on the staphylococcal exotoxin. Some strains produced more than one toxin, and each of the toxins (alpha and beta) could evoke a separate antitoxin. These toxins could be differentiated by their action on the red blood corpuscles of the rabbit and sheep. The alpha toxin, which probably played the major rôle in human infection, was hæmolytic, induced dermo-necrosis, and was lethal to animals; it also had the power of destroying the white blood corpuscles, and so contained a leucocidin. By incubating virulent staphylococcal exotoxin with formalin for several days, a toxoid was produced which could increase the titre of circulating antitoxin as much as 20 times. This produced an immunity in animals and an improvement in the clinical condition in man. In the treatment by toxoid injection a small dose of 0.05 c.cm. was used, gradually increased weekly according to the patient's reaction and condition, and to the blood antihæmolytic titre. In a small percentage of cases, local, focal, and general reactions occurred after the early injections of the series. It was wise therefore to start with very small doses when beginning treatment, or on resuming injections after an intermission. Eight injections usually cured furunculosis, but sycosis barbæ often required many more. Forty had been given in one case (12 c.cm.). The toxoid lost 40 per cent. of its antigenic power in six months in the ice-chest. In a series of 23 cases of sycosis barbæ and sycosis nuclæ treated with toxoid, 12 were regarded as cured, and the rest so improved that they ceased to attend the clinic. Of 24 cases of other staphylococcal infections, mainly furunculosis, 18 were cured and the remainder much improved. Antitoxin, given in an acute infection, could be followed during convalescence by injections of toxoid to stimulate and maintain the natural antitoxin of the patient at a high titre.

Dr. F. G. MORGAN (Melbourne) described his work at the Commonwealth laboratories in producing antitoxin. At present the serum was polyvalent, but he hoped the time would come when a serum of high antigenic value for any particular type of staphylococcal infection could be produced.

Dr. JOHN C. BELISARIO (Sydney) read a paper on

Mycological Infections

Vesicular eruptions on the feet and hands, he said, were very common in Sydney. There were several clinical types: (1) superficial vesicular and (2) deeper vesicular, both these being on the fingers, toes, palms of hands, and soles of feet; (3) localised type; (4) scaling or eczematoid type; (5) intertriginous type, remaining localised to the interdigital spaces; and (6) hyperkeratoid type. Many of the vesicular manifestations represented an allergic reaction of the tissues to toxins liberated from primary foci of infection. The numerous ætiological factors—seasons, exposure, foods, orthopædic abnormalities, and so forth—might all produce their effect by altering the reaction of the sweat. Normal sweat had an acid protecting cloak, but the sweat of the hands and feet was neutral or alkaline, owing to the absence of sebaceous glands and lack of evaporation. Alkaline sweat appeared to favour mycelial growth. Working on this hypothesis, lemon juice was tried; citric acid, apart from its effect on pH, also had a buffer action. The juice was used 4-5 times a day, in conjunction with liquor plumbi sub-acetate fort. and 1 per cent. hydrarg. ammon. dil. in a solution.

Irritation was dramatically relieved following this treatment, and the vesicles rapidly resolved. In the later stages, when eczema had supervened, ichthyol and salicylic applications were employed, supplemented if necessary by fractional doses of X rays. An infective focus must be eliminated to prevent recurrence. When the fungus element had died out, and sensitisation to external irritants remained, removal of toxic foci and autogenous vaccines might help. Intravenous calcium therapy and high colon lavage were also used with success in these types.

Dr. J. WITTON FLYNN (Sydney) said that epidermophyton was very common in Sydney, many cases being symptomless and ignored by the patient. Dressing sheds and gaols were places where the infection was easily spread. To check the disease the spread from one person to another must be prevented by keeping the feet covered and dry, and by dusting with a mild acid antiseptic powder. The floors of dressing sheds must also be kept as dry as possible. Reinfection could be prevented by treating the chronically inflamed toe-nails and correcting orthopædic faults. Whitfield's ointment was, in his experience, of little value.

Dr. S. W. SHIELDS (Melbourne) thought the disease more prevalent now owing to the increased amount of sport and to the popularity of trips to the tropics; moreover diagnosis was more accurate. The borrowing of towels in schools and camps was one of the common methods of infection. He had found Whitfield's ointment fairly satisfactory.

Dr. BUTLER (N.S.W.) said that at one time 90 per cent. of the military cadets at Duntroon had "Duntroon rot" between the toes. The use of lotio potassium permanganate before and after baths and boric acid between the toes produced good results, but where the nails were involved treatment was less effective.

The PRESIDENT thought that the variable results obtained with Whitfield's ointment might be explained by variation in its composition, and by the fact that some patients did not rub it in vigorously enough. Spiritous solutions of aniline dyes were well worth trying.

SECTION OF PHARMACOLOGY, THERAPEUTICS AND ANÆSTHESIA

Prof. SYDNEY SMITH presided at this section when Sir WILLIAM WILLCOX, on the

Use and Abuse of Hypnotic Drugs

He said that the advances in the study of hypnotics since 1913 included the discovery of many new derivatives of the barbituric acid series and the introduction of drugs other than alkaloids for basal anaesthesia. Insomnia was due either to psychological or organic causes and it was essential before commencing treatment to discover the cause. Hypnotics should be used only when absolutely necessary and when treatment by the usual general measures was unsuccessful. Patients taking hypnotics were likely to lose self-reliance and form the habit. Many operative cases did not require morphia or heroin, and as a routine they should not be administered post-operatively. Deaths from suppression of urine following their too free use were not uncommon. A dose of only 1/8 to 1/12 of a grain should be given, and repeated if necessary. The perfect hypnotic had

yet to be discovered. Sir William classified hypnotics into the following groups :—

Low toxicity group—e.g., bromides, alcohol, Phenazone, Pyramidon, phenacetin, aspirin.

Chloral and its associates.—Chloral was effective, safe, and rapid in action. Other drugs useful in this group were chloralamide, butyl chloral, chloralose, Chlorotone, paraldehyde (freely diluted) and Avertin. Avertin was used extensively as a basal anæsthetic. It sometimes produced toxic liver effects.

Urea group.—Adalin was very safe and very useful. It was best administered in a dose of 10 grains combined with a similar dose of aspirin.

Sulphone group.—Sulphonal and trional were examples; they were slow in action, uncertain, and toxic. Skin rashes and toxic symptoms were not uncommon following their use.

Barbituric acid group.—This group contained a great many preparations, whose toxicity depended on the molecular weight of the molecule combined with the barbituric acid; the heavier the molecular weight the greater the toxicity. They were quickly absorbed, certain, and very good in selected cases. Idiosyncrasy was not uncommon. Thyrotoxicosis, asthma and its related diseases, affections of the kidneys, liver, and adrenals rendered patients highly susceptible to barbiturates, and these should therefore be used only after such conditions had been excluded by thorough examination. Sir William cited cases of fatal suppression of urine and heart failure following Luminal. Repeated taking of normal doses could produce curious manifestations amongst which were diplopia, squint, visual hallucinations, ataxia, and degenerative changes of the central nervous system. These were frequently attributed to cerebral tumour or other intracranial diseases. Accumulation of effects occurred, but chemically no accumulation in the tissues could be detected even after long periods of administration. Tolerance was not established to barbiturates, but the habit of taking them could be formed. They caused amnesia, and in this way could be responsible for suicide; an actress had walked out of an open window following only a small dose of a barbiturate. In big doses these drugs not infrequently caused fatal pneumonia. Overdosage should be treated by bowel and gastric lavage, caffeine as a diuretic and drainage of cerebro-spinal fluid by lumbar or cisternal puncture. To cerebro-spinal fluid drainage many good results in treatment were attributed.

Alkaloidal hypnotics.—Morphia and heroin should not be used in the presence of hepatic or renal deficiency. In selected cases free but not prolonged use should be made of them, in adequate dosage. Apomorphine hypodermically was a good hypnotic in delirium tremens. It produced nausea followed by sleep.

Basal anæsthetics.—Amytal, Nembutal (grs. 5), Evipan, and others were useful but dangerous if idiosyncrasy existed. Sir William had seen a case of pneumonia after the administration of 3 grains of nembutal. In conclusion, he said that in prescribing a hypnotic or basal anæsthetic, one (or a combination) of the less toxic drugs should be selected. If a barbiturate were to be administered, the patient should be examined for the abnormalities likely to cause idiosyncrasy.

Prof. R. D. RUDOLF (Toronto) congratulated Sir William on his fair and moderate statement. He considered insomnia to be due either to increased irritability or increased irritation of the central

nervous system. Hypnotics acted mainly by lessening this irritability, but some actually relieved pain directly. Measures to lessen noise and worry were of the utmost importance, and should be undertaken before employing hypnotics. He agreed with Sir William that aspirin combined with a barbiturate was very effective.

Dr. F. DAVIES (Melbourne) asked whether barbiturates should be used in cases of pneumonia.

Dr. N. W. MARKWELL (Brisbane) said that chloral and bromide were the best hypnotics in pneumonia, especially for the post-febrile insomnia. For post-critical delirium chloroform anæsthesia and gastric lavage were used, but he gave 1 drachm of bromide hourly until sleep ensued. One patient had been given 1 ounce in 12 hours. He asked Sir William what was the best hypnotic in this condition. He pointed out that in coronary thrombosis large doses of morphia could be safely given. In cases of threatened nervous breakdown he used barbiturates in adequate dosage and stopped their use gradually.

Dr. D. G. REXTON (Melbourne) asked if a second dose of paraldehyde was less effective than the first, and whether barbiturates ever caused excitement. He gave his own experience of amnesia for 24 hours following 12 grains of sodium amytal administered in divided doses; in his own case morphia relieved pain but did not induce sleep. He confirmed the good effects of chloral and bromide.

Dr. W. SIMMONS (Sydney) asked what hypnotic Sir William recommended for the insomnia of pregnancy.

Dr. Z. MENNELL (London) said that he could not persuade Sir William to take a barbiturate for seasickness on the voyage out from England. Hedonal (not a barbiturate) was used frequently in Russia, where it was the cause of much pneumonia. He stressed the amnesia and the dangerous toxic symptoms produced by barbiturates in hypersensitive patients. Synergism played a large part and was well exemplified by the marked effect of small doses of morphia with barbiturates. Cerebro-spinal fluid drainage was of great value in treating toxic symptoms due to the barbiturates. Morphia was preferable to heroin because the former was less depressing to the respiratory centre. Depression to respiration by heroin was very marked when it was used in conjunction with evipan. Intravenous morphia was useful but great care was necessary.

Dr. B. L. STANTON (Melbourne) said there was an accumulation of effects following small doses of the barbiturates. This was evidenced by the marked effects produced by repeated small doses in the treatment of high blood pressure. The nervous irritability of children should be treated with small doses of barbiturates. He had treated a case of veronal poisoning with apomorphine, which did not produce vomiting but sent the patient into a deeper coma. This was evidence of synergism. The combination of codeine and aspirin was a good hypnotic and analgesic.

Dr. IVAN MAXWELL (Melbourne) said that ephedrine given in cases of asthma had often caused wakefulness, so he prescribed luminal or amytal as a sedative. Idiosyncrasy to small doses of aspirin was common in asthmatics, but no sensitivity to it was demonstrable in skin tests. He inquired whether luminal or bromide was preferable in the treatment of epilepsy.

Sir WILLIAM WILLCOX said that he did not recommend the use of barbiturates in pneumonia because no other drugs were so likely to cause broncho-pneumonia, and in addition they were not sufficiently powerful. For post-critical delirium he preferred hot packs and tepid sponges to drugs, which should only be used after physical measures had failed. He thought large doses of bromide were useful but would hesitate to use as much as 1 drachm hourly. However, the proof of the pudding was in the eating. He recommended that when barbiturates were required, well-known ones like veronal and Medinal should be prescribed. He agreed that a second dose of paraldehyde was not as effective as the first. Barbiturates often caused excitement. Morphia often relieved pain without inducing sleep, and sometimes caused excitement. The effects of the barbiturates were cumulative; a patient who had received 1 grain of luminal daily for one year had developed toxic jaundice. Veronal in usual doses took 2-3 days to be excreted. The barbiturates and morphia should not be used for the insomnia of pregnancy, since the effect of the hypnotic on the child had to be considered. It was best to adopt simple physical measures, and if hypnotics were required aspirin or alcohol should be administered.

Prof. W. A. OSBORNE (Melbourne) read a paper on a
Vasoconstrictor Principle in the Skin of the Frog (*Hyla Aurea*)

He said that when experimenting on a frog he happened to rub his eyes which immediately became very painful but not blood-shot. This chance observation led him to further experiments. He made an extract of the frog's skin which on injection constricted the peripheral arterioles, completely closing them. The heart stopped beating as a result of coronary spasm, and the blood pressure remained high. The experiment had been repeated and the result confirmed. He knew of no other drug which produced complete obliterative spasm of the arterioles. The effect of the extract was only slightly reduced by boiling. He suggested that this curious principle in the skin of the frog might some day find a clinical application.

Mr. JOHN TAIT (Melbourne) opened a discussion on
Urinary Antiseptics

He said that antiseptic drug treatment of infections of the pelvis of the kidney must be ineffective because the pelvis emptied so frequently. In determining what could be expected from drug treatment the basal pathology of the various urinary tract infections had to be considered. A great many infections were blood-borne. The gall-bladder had been the origin of the infection in one of his patients who had been cured of a chronic pyelitis by cholecystectomy. The majority of the infecting organisms came from the bowel. If they were not destroyed by the normal immunity mechanism they could cause urinary tract infections. Mental exhaustion was the main cause of impairment of the normal mechanism. Chronic pyelitis was a disease of professional people. A small number of cases of chronic pyelitis gave a history of bowel infections. There was great difficulty in curing these infections by drugs. Hexamine (urotropine) was the most useful. He quoted a case of chronic pyelitis who had been kept comfortable with hexamine for years. Hexamine should be given between meals when the gastric acidity was at its lowest. Hexyl resorcinol (Caprokol) was not more

efficacious than hexamine. Alkalisating the urine in cases of *B. coli* infections was often very effective. Some other *B. coli* infections were best treated by rendering the urine acid by a ketogenic diet and the administration of acid. In many cases a weekly alternation of the reaction of the urine was of great value.

Of the antiseptic dyes Pyridium and Neotropin were good and very penetrating. Flavine and mercurochrome applied locally were often effective in concentrations of 1 in 4000, but much higher ones could be used if the state of the kidney pelvis permitted. Intravenously these two drugs were not efficacious. A combination of methylene-blue and sandalwood oil was a good sedative antiseptic. It was desirable in addition to drug treatment to control the source of the infection, to build up the immunity response, and to promote a free flow of urine.

Mr. H. MORTENSEN (Melbourne) said the antiseptic properties of drugs depended on the form in which they were excreted in the urine. Some antiseptic drugs caused a beneficial effect by their diuretic action. Secondary infection was frequently the first sign of some lesion, such as calculus, of the urinary tract. The three types of urinary antiseptics were: those derived from plants, for example, buchu which probably acted by its diuretic effect; those having a direct antiseptic action; and those which altered the reaction of the urine. Hexamine and acriflavine were probably the best. Hexamine intravenously should be more often employed as a prophylactic after operative manipulation. Hexamine in a highly acid urine was most efficacious against *B. coli*. Ammonium chloride was better for acidifying the urine than was acid sodium phosphate, but it was irritating to the alimentary canal and might produce acidosis. N.A.B. was effective against coccal infections. When it was necessary to alkalisate the urine, large doses of potass. bicarb. or potass. citrate should be used. Beta-hydroxybutyric acid was the factor which inhibited *B. coli* in patients taking a ketogenic diet. A reaction of pH 5.2 to 4.6 was required in vitro. Twelve grammes of mandelic acid and 8 grammes of ammonium chloride daily were effective.

Dr. MAXWELL said that hexamine for its antiseptic action required a concentration of pH 5 and needed to be in contact with *B. coli* for six hours to destroy it. The pH was difficult to obtain clinically and it was almost impossible in cases of acute cystitis to keep the urine in the bladder for several hours. Similarly in pyelitis, contact with the antiseptic was not sufficiently long. Hexamine in cases of retained catheter did not prevent infection.

Sir WILLIAM WILLCOX agreed with the remarks of Mr. Tait and Mr. Mortensen. Changes of antiseptics were beneficial. One drachm of potassium citrate 3-4 times daily for 3-4 days at intervals of 3-4 days was useful. Metromene (methylene-blue and hexamine) was used a lot in England apparently with good results. An autogenous vaccine was of value in treatment and also vitamins A and D in building up immunity. Hexamine salicylate (Cylotropin) intravenously was effective in acute toxæmic conditions arising from the urinary tract.

Mr. MORTENSEN, replying to Dr. Maxwell, said he preferred catheterising a patient 2-3 times daily to having an indwelling catheter. He agreed with Sir William concerning the beneficial effects of cylotropin.

MALARIA IN CEYLON

MUCH that has been written about the epidemic of malaria in Ceylon is inaccurate or misleading; but with the publication of reports¹ by Colonel C. A. Gill and Dr. Rupert Briercliffe we now have an official account of it. Dr. Briercliffe is director of medical and sanitary services in the island; Colonel Gill, formerly chief malaria medical officer and director of public health, Punjab, was appointed as expert adviser on malaria by the Ceylon Government during the epidemic. The former states that his report is concerned chiefly with facts and figures, while the latter reviews the facts and defines the policy that should be followed by the Government of Ceylon in the future. From these reports we learn that the epidemic is the greatest pestilence in the recorded history of the island. In seven months it destroyed 80,000 lives, and indirectly it caused incalculable misery and distress; for it interrupted trade and business, paralysed village life, and led to an almost complete cessation of agricultural operations for a long period with consequent dire privation and starvation.

Although there had been previous epidemics on a large scale, and although two-thirds of the island—the north, east, and south-east parts of Ceylon—once densely populated, are now so malarial that they contain only about 4 per cent. of the population, this outburst came as a bolt from the blue. In the last week of October and first week of November, it appeared as an "explosive outbreak" in an area of about 5800 square miles. The peak of the epidemic as judged by sickness was in the middle of December, 1934, and as judged by mortality in the middle of January, 1935; from then it slowly declined except for a small rise in May and June. At the height of the epidemic there were 60,000 attendances a day at the government institutions in the affected area, and by the end of April 1½ million cases. Curiously enough this epidemic area was situated between the intensely malarial area in the north, and an area in the south-west, where there is little malaria normally, and which even during this epidemic was little affected.

Part of Colonel Gill's report is occupied by a discussion of the cause of the epidemic. He considers an epidemic "was due, if not overdue." He acknowledges very properly the valuable work during the past 12 years by Mr. H. F. Carter, medical entomologist, who had incriminated *Anopheles culicifacies* as the chief, if not the only important carrier of malaria in Ceylon, and who provided him with full information on the bionomics of the 18 species of anopheles in the island. *Culicifacies* breeds in rock and sandy pools in the beds of rivers, but it is also found in many other situations, like wells, borrow pits, quarries, drains, pools, and sheets of water formed during the rains. In most years the rains flush the rivers and sweep away the larvæ, but during droughts the larvæ are undisturbed and hatch out in enormous numbers; hence the association of malaria with rivers in Ceylon which has long been recognised. Colonel Gill sounds a warning that mosquito control in the river-beds alone is not likely to be successful.

The permanently malarial north, east, and south-east parts of Ceylon receive rain from the north-east monsoon in October, November, and December; in these there is a single malaria wave with a broad

peak in January, February, and March, and a slow descent to its minimum in June. In most of this area the rainfall is below 40 in. per annum and it is called the "dry zone." The remainder of Ceylon receives an average annual rainfall of more than 100 in., in places 200 in. In this "wet zone" are areas almost free from malaria; and others which, subject to moderate malaria, suffer most from the great epidemics. In the wet zone, a malaria wave appears twice a year; in January after the north-east monsoon; and in June, July, and August, after the south-west monsoon. Yet although the wet zone is subjected to two malaria waves in the year, the spleen-rate there is from 0-10 per cent. compared with 40-60 per cent. and over in the dry zone, and 10-40 per cent. in the intermediate area which suffered most during the recent epidemic. In all parts of Ceylon, except the central mountain region, temperature and humidity even during prolonged droughts remain favourable to the transmission of malaria by the insect carrier.

Colonel Gill discusses the distribution of the malaria and the epidemiology; but despite certain correlations between rainfall and malaria, and full entomological data, "the entomological theory does not appear competent to explain the whole phenomenon presented by the epidemic and the intriguing paradox therefore remains that malaria epidemics in tropical Ceylon are determined by drought, whilst in sub-tropical India they follow excessive rainfall." An attempt is made to explain the paradox, by suggesting a periodicity of the parasite, "possibly the quality variously referred to as 'the unknown influence', the 'X factor' of Pettenkofer, 'the epidemic potential' and 'the general determining cause' of modern epidemiologists. Whatever may be its nature, the predominant attribute attaching to periodicity is the variable amplitude of its range." If other conditions are not favourable even this universal "influence" cannot produce an epidemic. And so in spite of a highly congested population containing a high percentage of susceptible children, in spite of the presence of drought, in spite of special hardships from economic conditions, and in spite of the presence of river-beds, the "influence" had little effect in the south-west area of the island, where the carrier insect, although present was not widely prevalent. Nor had the "influence" much effect on the permanently higher malarial area.

SYMPTOMS AND TREATMENT

On the clinical side the predominating parasite is reported as *Plasmodium vivax*; but there is some doubt whether the microscopic work in many hospitals was accurate. A special study of 647 cases showed that besides the common type of fever, there were cerebral cases, algid cases, diarrhoeal and dysenteric types, œdematous types, and malaria complicating pregnancy often with disastrous results. In the treatment of malaria during pregnancy Dr. G. A. W. Wickramasuriya considered that "far from being an oxytocic, quinine administered in effective therapeutic doses, by rapidly controlling the malarial infection and the high temperature, prevents premature interruptions of pregnancy and intra-uterine foetal death," and his views have been generally confirmed by other medical officers. The association of ankylostomiasis, or malnutrition, with malaria was regarded as the cause of the partial or generalised œdema which occurred in a large number of cases in the later stages of the epidemic, chiefly among children.

Atebrin and Atebrin mussonate were used in

¹ Report by Director of Medical and Sanitary Services (sessional paper XXII.), with supplement containing maps and charts; and Report by Colonel Gill (sessional paper XXIII.), Published in September, 1935, and obtainable from the Government Record Office, Colombo, at Rs.4.50 and Rs.3.0 respectively.

hospitals, but were not considered suitable for use at dispensaries and in the field owing to their toxic effects. Comparing atabrin and quinine an appendix to Dr. Brierecliffe's report states:—

"Deaths.—Among 681 patients treated with atabrin mussonate 17 or 2.5 per cent. died and among 424 treated with quinine 6 or 1.4 per cent. died. Four of the 17 deaths following atabrin mussonate were attributed to the toxic effect of the drug. If these four cases are excluded, the natural death-rate among the atabrin treated cases would have been 1.9 per cent., which is not significantly greater than the death-rate for the quinine treated series."

Discussing the toxic effects and the sudden deaths after atabrin injections, the appendix states that—

"among adults, pregnant women have been found particularly liable to collapse after injections. Convulsions due to malaria were of frequent occurrence among children in the early stages of the epidemic. Convulsions occurring a few minutes or hours after an atabrin injection and attributed by the medical officer concerned to the atabrin injection have occurred in both children and adults. They were always fatal."

PROPOSALS FOR THE FUTURE

In Part II. of his report, on the Control of Malaria in Ceylon, Colonel Gill discusses the scientific problem under the headings, the mosquito factor, the parasite factor, and the human factor, and summarises this by saying endemic malaria in Ceylon presents no novel or remarkable features. Although these epidemics have hitherto been regarded as uncontrollable, there is now reason to believe that their emergence can be prevented if measures are taken that will reduce the spleen-rate and the anopheline-rate (*A. culicifacies*) to the level of these factors in the south-west healthy area. This will take time, but can be accomplished if medical science provides the technical knowledge, Government the machinery, and public opinion the motive power. Government having decided that the population is sufficiently advanced politically to control its own internal administration, the success of the scheme will depend on the actual coöperation of the people. Colonel Gill reminds them that so far only a few antimalarial schemes had been begun in Ceylon, and had achieved only a certain measure of success—not from any fault in the schemes, but from lack of popular interest resulting in a lack of funds to complete or maintain them. The recent epidemic, however, has produced a profound change in public opinion.

No attempt is made to frame an antimalarial scheme for adoption in each individual area. Colonel Gill recommends generous provision of hospital facilities and that apothecaries and dispensers in the Government and estate hospitals and dispensaries be replaced by registered medical practitioners provided with microscopes, so that diagnosis and treatment may be more accurate; this is to control the parasite factor in man. Malaria control schemes should be undertaken in urban, rural, and estate areas; by land drainage, irrigation and development schemes, and river training operations. He deprecates colonisation schemes which involve the introduction of non-immune settlers into hyperendemic areas; and he considers antimalarial measures in such areas will not be effective unless accompanied by measures designed to promote rural betterment by increasing the food-supply and relieving economic distress.

The recommendations include establishment of a Sanitary Works Board, with the Minister of Local Government as president, and an equal number of official and unofficial members. It is also advised that an Anti-Mosquito Ordinance be passed. A proposal had been made to erect a Malaria Research

Institute in commemoration of the Jubilee; Colonel Gill recommends that a malaria department be accommodated in a wing of a main institute. He states his proposals will cost money; "good health, including freedom from malaria, is a purchasable commodity, but it is doubtful whether it is worth having as a free gift." Financially stricken as the island has been by the world depression and the great epidemic of malaria, the Government and people of Ceylon have now the anxious task of deciding how the maximum benefit is to be obtained from the minimum expenditure; which of Colonel Gill's recommendations are to be carried out now and which postponed; for Colonel Gill says "of this 'balanced scheme' that 'many parts indeed can be postponed or omitted without destroying its general structure.'"

THE CONGRESS OF DERMATOLOGY

(FROM OUR BUDAPEST CORRESPONDENT)

THE Ninth International Congress of Dermatology and Syphilology has been memorable both for its unprecedented size and for its scope. Dermatology, it was apparent, ranges widely through the whole field of medicine; and without attempting to summarise the hundreds of addresses delivered I will endeavour to convey something of the catholic outlook they revealed.

VENEREAL DISEASES

During the first few days venereal disease was considered from the international standpoint. It was accepted as a fact that syphilis and gonorrhoea could be made extinct throughout the world within a single year if all who suffer from them would have themselves fully treated. Starting from this principle the Congress proposed the application of legal penalties and the State control of treatment, together with the regulation of prostitution. From this it passed on to discuss some of the social questions arising in the practice of dermatology and venereology, including out-patient dispensaries, sick clubs, beauty specialists, barbers, masseurs, and quacks. Prof. KERL (Vienna), in an address lasting several hours, pointed out that while specialists in dermatology and venereal diseases keep strictly to their own territory, practitioners in adjacent fields press ever harder on their confines; indeed, it is often suggested that the treatment of syphilis is rather the business of the internist and the neurologist than of the venereologist! Kerl's idea is that the latter must gain exact knowledge of the borderland of his subject—even if it means adding a couple of years to his training—and that when he has such knowledge even neurosyphilitic affections should come within his province.

ALMQUIST (Stockholm) early created a sensation by proposing that the present division of syphilis into three stages should be abandoned; by means of many histological preparations he demonstrated that this infection, at all stages and in all places, will always produce what is essentially the same lesion. This view was accepted by many other pathologists present but on the whole was considered unproven. GRUNBERG, who has been studying the nature of the Wassermann reaction, reported that he has obtained positive tests from healthy animals treated with "spirochaete lipoids," whereas previous treatment with non-specific "organ lipoids" did not yield the same results. SCHERESCHWITZKY (Paris) made known his successes in the treatment of syphilis

in animals by means of a quinine preparation of his own, but it was felt that further evidence of its efficacy was required. Also in the discussions on syphilis an interesting dispute arose between ARZT and KERL, both leading clinicians of Vienna, about the importance to be attached to early changes in the cerebro-spinal fluid. ARZT looks on these changes as an indication for treatment with malaria, whereas KERL upholds the conventional view that they are mostly transitory. PINARD (Paris) took the view that fever therapy is desirable in syphilis (1) if the blood-serum is obstinately positive, or (2) if there is a positive Wassermann reaction of the cerebro-spinal fluid or other evidence of neurosyphilis. If the blood Wassermann cannot be made negative he prefers sulphur; in neurosyphilis and G.P.I. he uses malaria, or sulphur if it fails. LUDWIG WINKLER (Oradea, Rumania) drew attention to his priority as advocate of sulphur therapy in neurosyphilis, and spoke of its value in cardiovascular and arthritic syphilis as well. He also referred to the importance of estimating the erythrocyte sedimentation-rate as a control of cure of syphilitic infection. HILGERMAN (Landsberg) and SPITZER (Vienna) gave an account of their method of inoculation with a spirochæte vaccine, which they believe makes the organisms of syphilis accessible to chemotherapy.

The five largest American clinics reported their experience of cardiovascular syphilis; it appeared that in 6253 cases of syphilis—treated early, late, satisfactorily, unsatisfactorily, or not at all—the percentage of cardiovascular complications was 9.9; while in the smaller group, comprising only those which had not been treated early enough, it was 23 per cent. The Americans are the champions of uninterrupted treatment at all stages of syphilis.

Gonorrhœa did not receive as much attention as sometimes. Austrian and German members of the Congress expressed doubt about the value of the serological reaction, which they considered very problematical; VERESS (Cluj) thought it unduly optimistic to use this reaction as a criterion for treatment. As regards actual remedies no advance worth mentioning seems to have been made during the past few years. The horse serum injections proposed by Szilvassy have proved useless in GUSZMANN'S hands, and all the speakers seemed to agree that vaccines are valueless in the acute stage, while their action on complications is probably not specific. Of new preparations methylene-blue and acridine dyes seem to be the only ones which represent an improvement. Goldberger's abortive cure with Trypaflavine was received very dubiously, and some rejected it altogether.

SKIN DISEASE AND THE BODY AS A WHOLE

With the object of increasing the international solidarity of dermatologists a number of committees were appointed to go into such problems as cutaneous tuberculosis, industrial and other environmental affections of the skin, and the classification and nomenclature of skin disease. This last committee, under the leadership of Howard Fox of New York, is faced with a difficult task of reconciling many different attitudes; it has to bear in mind the different effects of identical causes and the identical effects of different causes, the individuality of the patient, the transitory nature of symptoms, the varying virulence of maladies, and the accumulation of diverse processes. In the present state of knowledge no system of eternal validity can be laid down, but one can imagine a working classification which would adapt itself to the advance of knowledge.

DARIER (Paris), MAYR (Munster), and STEIN (Vienna) spoke of the importance of the skin as an organ, especially in relation to diuresis and dys-hidrosis. Too much attention, they feel, has been given to the heat-regulating function of the skin and not enough to the excretory. It is significant that in pemphigus, for example, the quantity of urine passed decreases to a minimum, simply because of the excessive external loss of fluid. With the fluid goes sodium chloride, and the chloride excretion in the urine is reduced—an effect which may easily give rise to a mistaken impression that renal function is impaired. Means of testing the normality or abnormality of the skin as an organ are provided by the injection of such drugs as atropine and pilocarpine, which respectively promote and decrease sweating but have no influence on a sick skin. Caffeine doubles perspiration under normal circumstances but again may have no action when cutaneous function is already damaged. Such tests can be performed with delicate and complicated but reliable instruments. Stein also spoke of the elimination of toxins through the skin: the old exponents of humoral pathology used to maintain that all skin diseases were due to poisonous substances inside the body, and though this is an exaggeration many such diseases are really connected with puberty, pregnancy, and the menopause, and presumably with poisonous substances produced in these states. Juvenile acne, for instance, begins in puberty and is seldom seen after 40 years of age, and Stein has made the interesting observation that it occurs (almost without exception) in children who are precociously mature, and never, on the other hand, in eunuchs. Is it any wonder that another lecturer should urge the necessity for exact endocrinological tests in cases of obstinate skin disease?

Much was said about the action of vitamins on the skin, and several speakers assumed that they have a preventive or curative action; a Hague professor, for example, reported good results from the use of vitamin-rich raw foods in conditions such as psoriasis and eczema. The importance of dietetic treatment in skin diseases where the patient suffers also from digestive disorders was fully recognised. Due consideration again was given to the rôle of focal infections.

LEVADITI (Paris), NICOLAU (Bucharest), and others introduced the important subject of the filtrable viruses, and spoke of the proof that lymphogranuloma inguinale is due to a virus and can be recognised with the Frey antigen. URBACH and WOLFRAM reported that pemphigus vulgaris and dermatitis herpetiformis are likewise due to a virus, while NEUBER (Debrecen) stated that rhinoscleroma is caused by a capsulated bacillus—findings which will be of great interest provided that they can be corroborated. MANNSHEIMER (Essen) brought forward statistics supporting the Russian view that lupus in its ætiology has nothing to do with pulmonary tuberculosis. He denies that phthisical patients are particularly liable to contract lupus; indeed, he finds that their illness tends more towards recovery when they do so. Also speaking on lupus, ATKEN (Edinburgh) said that among 270–280 cases he had found that about half followed tuberculous infection of glands of the neck. It was very important, he said, that practitioners should recognise the great value of ultra-violet irradiation for tuberculous adenitis.

Elsewhere the Congress provided evidence of a reaction against methods of irradiation in dermatology; it was evidently felt that these have been

carried to excess. FRANCIS POLLER has not found short and ultra-short wave therapy particularly valuable; physicians from the United States quoted cases which suggest that diathermy is just as efficacious.

To sum up, although this Ninth Congress brought no great new discovery it has cleared up many problems of diagnosis and treatment and brought out new principles and objectives. Apart from skin diseases caused by external infections, it seems that the time is not far distant when the use of ointments in dermatology will be almost extinct. What has become chiefly important, for efficient diagnosis and for efficient treatment, is a knowledge not of the changes discovered but of their underlying causes.

LONDON WATER SOME PRESENT-DAY PROBLEMS

Colonel Harold's first report¹ as Director of Water Examination to the Metropolitan Water Board is full of interest, for, as he says, he came from the comparative quiet of a peace-time army into the heart of the Board's operations at a time of national emergency arising from two years' drought when it became necessary to consider matters of high policy. London was, however, saved from anything more than anxiety and inconvenience owing to the huge storage systems built up in accordance with the wise policy of his predecessor; and the danger being over Colonel Harold feels free to poke a little fun at the Londoner who talks about a condition of drought when he has sufficient water for all purposes, including a daily long bath. He compares it with the water shortage of an Eastern war-time cantonment, where the daily issue resolved itself into a petrol drum of water, derived from brackish underground sources, receiving the unpurified road washings of an unpaved Eastern town. But the shortage of water in London, such as it was, led to the relaxation of a provision in the Thames Conservancy Act of 1932 that every day 170 million gallons of water must pass over Teddington Weir. This eased the situation, but the reduced flow of the river must have reacted on the condition of the tidal reaches if only to a small extent. At Barking sewage carried upstream by the tide gave rise to many complaints from those using piers and boats. The total volume of water in the Thames between Barking Creek and Teddington Weir amounts at low tide only to some 8000 million gallons and the average content is 15,700 gallons, while the incoming water each tide is about double the low tide figure. The minimum statutory flow of fresh water over Teddington Weir of 170 million gallons per day obviously bears to the average volume mentioned the ratio of 170 to 15,700 or 1 to 93. A reduction of 30 million gallons per day in the statutory flow would change this ratio of fresh to tidal water to 1 to 113, a change which could have little adverse effect on the Pool of London. Also it should not be overlooked that some of the extra water abstracted from the river must ultimately reach the sewers and dilute the effluent which is passed into the Thames.

TASTE TROUBLES

Apart from this special source of complaint London consumers found little to grumble about last year. The complaints reaching the offices of the Board

numbered no more than one three-thousandth of a per cent. of population served. Only half of these were complaints about taste, and again only half were accepted as valid after investigation. Strictly speaking the responsibility at law of the Water Board terminates at its mains—no small liability in itself for there are 7760 miles of them. But in practice all complaints are investigated on account of the light which they may throw on adventitious pollution. During the year definite pollution was twice traced to cross connexions of piping in important buildings. Generally speaking, Colonel Harold says, most of the complaints arise from local causes beyond the mains. The tank room offers great attractions as a playground on wet days and the household storage system is a fertile source of pollution. In one case, where a complaint was made that tap water was unfit for dispensing, inquiry revealed an aggregation of lead, shavings, and oakum left in the pipe by the plumber. Evidently every consumer should demand of his landlord a tap direct off the main for drinking purposes. In periods of high atmospheric temperature complaints of a disinfectant taste were sometimes received and later of an earthy taste at the time when a profuse growth of algae dies on the filter beds. But, all in all, London water is no mean beverage, and its palatability may be largely attributed to its moderate hardness. During the year a committee of residents in West Wickham, after wide investigation, concluded that whilst it would be possible for their water to be softened, that would on balance be no advantage to the community.

OZONE OR CHLORINE

But the scientific interest of the present report is greatest in the big issue which will soon have to be decided as to the choice of the final disinfecting agent in water purification. The drought brought to light defects in the filtration system as a result of which chlorine and ammonia points have been installed in many places as an additional safeguard. The continuous flow of water through storage systems results in an enormous reduction of the bacterial and organic content of the water. Next comes an efficient filter barrier, and finally a chemical process which needs time for effective action either in contact tanks or in the mains before the draw off. The aim of successful water practice is to supply a worked-out weathered water with a composition like the unpolluted natural water, and in contradistinction to campaigning measures chemicals are used only as a finishing process and as a corrective to counter an emergency. The importance of such an invulnerable barrier is illustrated by an incident at Milwaukee in 1916, when the chlorine was accidentally shut off for several hours and the water was badly polluted for one day. The result of this was 25,000 to 100,000 cases of diarrhoea followed by about 500 cases of typhoid fever with 60 deaths. The choice of final process for London water rests between ozone and chlorine—or rather combinations of chlorine and ammonia, for free chlorine is no longer used. Ozone imparts an excellent finish to water and removes the majority of disagreeable tastes. When it has done its work it leaves nothing behind but oxygen. A water cannot be overdosed with ozone, since the gas is ultimately dissipated. Ozone is increasingly popular in France and has been tried out at one of the Board's works at Barn Elms. But whereas chloramine continues to function as an efficient germicide under the worst possible conditions, ozone requires a filtrate of fairly uniform quality. On the other hand, with ozone the contact period

¹Metropolitan Water Board. 29th Annual Report by Lt.-Col. C. H. Harold, O.B.E., M.D., D.P.H. London: P. S. King and Son. 10s. 6d.

need be only a few minutes, in contrast with the one and a half to two hours contact required in the tank after a standard dose of ammonia and chlorine. But then again the longer contact period may provide, and not infrequently does, a completely sterile water. There is a further suggestion, which requires careful examination, that ozonised water after exhaustion of the ozone becomes more susceptible to bacterial growth. Colonel Harold sums up the situation thus. From the consumer's point of view, ozone presents the greater attraction, and if properly applied is an effective sterilant, provided that at all times an absence of breaches in the filter barrier can be guaranteed. On the other hand, chloramine offers an all-round security under every possible condition and is the safety-first of waterworks practice.

AMERICAN PUBLIC HEALTH ASSOCIATION

(FROM AN OCCASIONAL CORRESPONDENT)

MORE than two thousand fellows, members, and guests of this association were registered at the annual meeting held at Milwaukee, Wisconsin, from Oct. 7th to 10th. This is the largest attendance recorded since a registration fee was inaugurated.

Poliomyelitis

The summer epidemic of poliomyelitis and the resulting popular excitement had their effect upon the programme. The governing council voted the creation of a special committee to confer with the U.S. public health service and to announce to the press and to the public whenever it may be necessary such dicta regarding the administrative control of poliomyelitis as may be calculated to allay panic and quiet or prevent unreasonable agitation. As to whether there is any knowledge to disseminate a difference of opinion was expressed. The epidemiologists state that we know at least as much about poliomyelitis as about scarlet fever. An experienced health officer retorts by saying that if every health officer died to-morrow there would be neither more nor less poliomyelitis as a result. Dr. James P. Leake, senior surgeon U.S. public health service, made an effective plea for the reporting of paralysis whenever it occurs. In North Carolina, where this year's epidemic began (in April), 90 per cent. of the cases reported were paralytic. This is a quite unusually high proportion. In New York, where there was an excess incidence though hardly an epidemic, 55 per cent. of the cases were paralytic.

This summer gave occasion for the trial on a fairly large scale of the vaccines prepared by Dr. Kolmer and Dr. Brodie. Dr. Kolmer's vaccine is a living attenuated virus. It was given to some 12,000 persons, nine of whom subsequently developed poliomyelitis, eight of them with paralysis. Dr. Kolmer is convinced that in each case the disease was in the stage of incubation and developed because the vaccine was given too late to produce immunity. His critics, however, are not satisfied that there was no causal relationship between vaccination and pathogenesis. They refuse to regard the living vaccine as safe. Dr. Brodie's vaccine prepared in the laboratories of the New York City department of health is a killed vaccine. It has been given to 8000 persons and one only has developed poliomyelitis. The vaccine given in this one case had received three times the treatment needed to make

it non-infectious to monkeys and had in addition been shipped from New York to the west coast. The disease developed well within the period of incubation from the date of known exposure. Critics accept the safety of Dr. Brodie's vaccine, but consider further experience necessary to prove its efficacy. So indeed does Dr. Brodie, who is refusing to supply his vaccine except for properly controlled experimentation.

Whooping-cough

Dr. Louis W. Sauer reported on results obtained with his pertussis vaccine which is now being used extensively by physicians in this country. Dr. Sauer sees no evidence that pertussis vaccine has therapeutic value. However, with vaccine prepared and administered in the Evanston Hospital he had had complete success in prophylaxis. With "authorised" commercial vaccine the success has been less complete as is shown in the following Table.

Three-year Report on Pertussis Immunisation

Authorised commercial vaccine (Sauer) 8 c.cm.	Injected.	Exposed		Failures.
		family.	outside.	
Private	475	30	28	5
Health Department .	612	13	50	4
Two orphanages ..	242	23	—	1
Cradle (illegit. infants)	187	—	—	—
—	1516	144	—	10

Unsolicited reports have been received from 58 physicians in 22 different States, the total figures given being 6455 patients injected, 476 exposed, and 81 failures. The high proportion of failures to exposures and the low proportion of exposures to injected are explained on the ground that many of these physicians had no means of knowing of exposures except in such cases as subsequently developed the disease.

Every attempt has been made to ensure that the "authorised" commercial vaccine shall be prepared by exactly the same methods as those used in Dr. Sauer's laboratory in Evanston. Three possible causes of failure were discussed: (1) The warming of the vaccine. At the Evanston Hospital this is not allowed to take place at any time between preparation and administration. In distribution of commercial vaccine over the country uninterrupted refrigeration has not been practicable. (2) Age of administration. Seven out of ten failures occurred in children over 3 years of age. As a result of this observation Dr. Sauer is now recommending that children over 3 years receive a total dose of not less than 10 c.cm. (3) Use of recently isolated strains. In preparation of commercial vaccines there may be difficulty in obtaining recently isolated strains. Microphotographs were displayed showing the marked changes in morphology undergone by *B. pertussis* in culture.

Mental Hygiene

Dr. Elizabeth I. Adamson, of the department of psychiatry, Columbia University, made a strong point for the inclusion of this subject in official public health programmes when she pointed out that psychogenic illness, like tuberculosis, is mainly acquired in childhood and is a family disease communicated by prolonged and repeated exposure. Prof. Grant Fleming, of McGill University, while

accepting the wisdom of proceeding slowly in making additions to the official health programme, encouraged voluntary organisations to blaze the trail and described how existing institutions in Canada might be used as centres around which provincial mental hygiene organisations can be created.

Lay Administrators

In the report of the committee on professional education, the following passages gave rise to much comment and some criticism:

In practice in the United States there have been in the past many non-medical health officers, some of whom have served with such distinction as to demonstrate conclusively that a suitably educated individual, not a doctor of medicine, can administer a health department efficiently and well.

While there are many positions in the field of public health which can well or best be filled by workers well educated in the theory and practice of public health but not possessing a medical degree, the position of administrative health officer, whether of state, city or county, demands in general the possession of medical as well as public health training. We do not recommend the discontinuance of courses in public health for the education of non-medical persons, but the committee believes that such persons should be informed before entering on a course that their probable field of activity will be curtailed by the absence of a medical degree, and that their chances of succeeding to an important administrative position in the field of public health are not bright. Young men and women intending to enter the field of administrative public health should be advised to secure a medical degree, specialising as much as possible during the medical course in the various fields of preventive medicine, and adding the special course in public health at the end of the usual hospital internship. It is from such a group that most may be expected in the coming years.

The remarkable personality and teaching ability of the late Prof. Sedgwick is responsible for a group of highly successful lay public health administrators. It is still uncertain and perhaps will for some years remain uncertain to what extent the non-medical public health officer can win a place for himself in public health administration in this country. Should he choose to specialise in social welfare as well as in public health there is a distinct possibility that his prospects may be brighter than this report would indicate.

The new president-elect is Dr. Thomas Parran, Jun., health commissioner of New York State, the president being Dr. Walter H. Brown, professor of hygiene at Stanford University. New Orleans was selected as the convention city for 1936.

MEDICINE AND THE LAW

Damages for Shortened Life

In *Rose v. Ford*, which came before the Court of Appeal last month, further light was thrown on the change in the law whereby a right to damages for negligence can now survive for the benefit of a dead person's estate. This class of case is of interest as showing the attitude of the courts to the assessment of damages for shortened expectation of life and similar questions. At Birmingham Assizes Mr. Justice Travers Humphreys had to consider the case of a girl who, as the result of a motorist's negligence, was injured fatally. Soon after the accident her leg was amputated; two days after the amputation she died. The judge had awarded to her repre-

sentatives £500 for her pain and suffering and for the loss of the limb, and £500 for the more remote damage she would have suffered in going through life as a woman with only one leg. The Court of Appeal cut down the first £500 to £20, and the second £500 to 40s. The girl had lost her leg only two days before she died and the judges held that the nominal sum of 40s. would be enough for those 48 hours. The judge at assizes was apparently wrong in thinking that the girl's estate could recover damages on the basis of a normal expectancy of life after the amputation.

"Punch-drunk" Boxer's Plea of Insanity

In an application to the Court of Criminal Appeal (in *R. v. Bousquet*, Oct. 14th) Sir Henry Curtis Bennett, K.C., urged that his client, a professional boxer, had been insane at the time of the alleged murder owing to his being "punch-drunk"—i.e., mentally affected by the blows and bruises he had received in the course of his career as a heavy-weight fighter. A witness at the trial had said that a "punch-drunk" boxer would not know what he was about. It was suggested that Bousquet had not been normal since last February, and that his condition had been getting steadily worse. His letters and statements were damaging evidence of guilty intent; the defence contended that they were delusions. The Lord Chief Justice delivered the judgment of the court which rejected the application. Dr. Grierson, a medical officer of long experience in the prison service, had said that there was no evidence of insanity. Lord Hewart enumerated the three points which the accused had to establish: (1) that he suffered from a disease of the mind; (2) that because of such disease he suffered from a defect of reason; and (3) that, in killing his victim, he did not know the nature and quality of his act—as if, for instance, he thought he was merely peeling an apple when he was actually cutting someone's throat. The defence had failed to establish these points and the failure was final.

The Use of Films as Criminal Records

Two days after the decision in *Hauptmann's* case at Trenton in New Jersey (set out in this column last week), an Inter-State conference on crime prevention was held in the same building. It was specially concerned to remove obstacles due to the separate and independent jurisdictions of the several States of America. If a gunman commits a murder and can slip over the border into an adjoining State, he will probably escape the consequences of his crime. The conference decided that the States would make compacts with one another for the surrender of criminals, the summoning of witnesses, and the checking of prisoners released on parole; in effect, the State boundaries would cease to exist. The conference also recommended the adoption of universal finger-printing throughout all the States and the provision of facilities for interchange of criminal records. One other resolution reveals an interesting element of psychology. It advocated the trial and use of "sound moving pictures" in the identification of criminals. The New Jersey suggestion is that a film be taken of persons convicted of serious crimes. The man will be shown moving along a platform and standing against a chart of Bertillon measurements. At present detectives see him under these conditions on conviction, but a film record would refresh their memory in later years and might be exhibited in

public cinemas when the man, as sometimes happens, is "wanted" for another serious offence after his release from serving his sentence for an earlier crime.

Nor is this all. It is said to be the experience of the police that a criminal, when caught, will sometimes volunteer a frank confession to assist the cause of justice or to relieve his own conscience, yet will afterwards repudiate his confession or will falsely allege that it was extracted from him by "third-degree" methods. The New Jersey police have the idea of using the sound-recording film, along with the ordinary cinematograph film, to record the confession at the moment when the criminal is in the mood to tell his story. If the record can show him making his statement voluntarily, deliberately, and at his ease, if it can show the police giving him a proper caution and warning him that his statement may be used against him, and that he must expect no advantage from it, then it may some day be available to negative a sudden and unsupported allegation that the man was "beaten up" or unfairly forced to confess. It may be doubtful whether we shall adopt this idea in England, but the proposal is interesting. The recent Inter-State Conference at Trenton indicates that Americans are at last being stirred to some active step to put down crime. The proposed system of Inter-State compacts to avoid awkwardness on State boundaries will recall the compacts sometimes made in England between local authorities to avoid unfortunate incidents on their boundaries in connexion with motor-ambulances and traffic victims. In America the question of crime in relation to State boundaries could best be solved by Federal legislation. This, however, might require a new amendment of the United States Constitution, and at the present moment Federal intervention in State matters is far from popular.

MEDICAL USES OF RADIUM

THE research centres throughout the country to which radium has been lent by the Medical Research Council submit reports this year¹ showing good progress and evidence that much thought is being given to improvements in technique. We select from the reports some items of special interest.

Cancer of the Breast.—The surgical unit of St. Bartholomew's Hospital makes an interesting statement concerning the comparative results of surgical operation and radium implants in the treatment of breast cancer. Examination of the five-year survival rates obtained by very careful follow-up shows that the results for the two methods of treatment are not materially different, being in each case 40 per cent. Since the new form of treatment did not prove superior to the old, it was decided to attempt improvement by combining interstitial radium with surgery, the breast being first implanted with radium needles and subsequently excised. It is hoped that by this autumn a special histological study of 50 cases treated by this method will have been completed, and the next report will contain an account of these. Birmingham General Hospital, where many breast cases are treated radiologically, the Marie Curie Hospital and the Middlesex Hospital all mention the use of X ray therapy either to supplement or to replace radium, suggesting that all are finding here a satisfactory line of advance.

Cancer of the Uterine Cervix.—Figures are now available of over 1000 cases of cancer of the cervix treated more than five years ago, and some interesting comparisons are possible. Presumably in future years survival tables will be supplied such as have recently been recommended by the League of Nations Health Organisation as a result of the inquiry made by a committee of experts under the chairmanship of Prof. James Heyman.² Tables of this sort are now prepared by nearly all research centres.

Of all types of cancer treated by radium the results are most consistent in cancer of the cervix, and although certain figures are still outstanding there is a suggestion, in the tables for the last three years, of a general improvement.

Cancer of the Uterine Body.—Most centres mention that hysterectomy remains the method of choice for early cases. It seems possible, however, that in the future a combined treatment by radium and X ray may replace surgery except in very favourable cases.

Oral Cancer.—This section includes reports from two hospitals where one-gramme units are in operation. The Middlesex Hospital states, "The tele-radium unit has continued to prove its usefulness. . . . Quite apart from the curative value, which cannot be assessed until after a period of years has elapsed, it is a method of therapy which is more convenient and associated with less danger to the staff than is the case when large moulded applicators are used." University College Hospital point out the difficulty of so arranging the ports of entry that an adequate tumour dose is obtained, and believe that the solution of the difficulty lies in the direction of increased radium skin distance with the corresponding increase of radium element. The survival rate of cases of cancer in the oral cavity treated more than three years ago tends to be disappointing.

Cancer of the Rectum.—An interesting description is given of the technique in use at St. Bartholomew's Hospital for cancer of the posterior wall. This consists of perirectal needles passed through the perineal skin, and an ingenious arrangement of intracavitary radium on a rubber plaque pulled up by means of a tube passed through the colostomy opening. It is generally believed that radiation gives negligible results in the treatment of rectal cancer, but although the percentage of survivals is low the figures show that it is possible to cure the condition even when radical operation cannot be performed.

Sarcoma.—One or two cases giving a favourable response to radiation therapy are quoted, but the difficulty of accurate diagnosis, and the poor results in the proved cases of sarcoma of bone, suggest that detailed analysis is necessary before any conclusions can be drawn as to the value of irradiating the various forms of tumour derived from the mesoblastic elements.

Biopsy.—Workers at the Bland Sutton Institute of pathology at the Middlesex Hospital have been making routine confirmatory diagnoses of the presence of growth, with analysis of the type of growth present. In some of the cases the portion of tissue for section has been removed after electro-coagulation of the area, and such material is said to give reasonably good histological preparations. The advantages of this procedure include the following: (1) it is possible risk of dissemination of the growth is minimised; (2) it is more likely that a piece of tissue will be removed. (3) the reaction of the tissue does not interfere with the subsequent treatment of the patient.

¹ Report to the Council on the Work of the Health Committee, Geneva, 1935, 7th to 14th, London: Allen and Unwin Ltd.

² Medical Uses of Radium. Medical Research Council, Special Report Series No. 204. H.M. Stationery Office. 1935. Pp. 45. 1s.

The future of voluntary hospitals in Scotland was discussed last week at a meeting in Edinburgh of the Committee on Scottish Health Services. It was submitted by witnesses on behalf of the voluntary hospitals that their future depends on the attitude of the State and local authorities towards them during the next five years. Voluntary hospitals had approved the provisions of the Local Government Act, but its working had not been satisfactory. The local authorities had not proceeded on the principle of coöperation. It was urged that the voluntary hospitals should be officially recognised by the State as an essential factor in the health services, and that

a thoroughly representative organisation should be set up to bring them directly and officially into touch with the Department of Health for Scotland. The witnesses stated that the inadequacy of medical attention at home added greatly to their work, especially for children.

This whole subject bristles with difficulties. Local authorities are at present attempting to construct hospital services which will equal those provided by the voluntary hospitals. If the voluntary hospitals are able to maintain their present standard of efficiency, they are likely to remain the centres of the profession in Scotland. It is arguable that the State or local authority should see that the efficiency of the voluntary hospitals does not suffer from lack of funds. Any attempt, however, by the local authorities to control the management of the voluntary hospitals is bound to meet with strong resistance.

VIENNA

(FROM OUR OWN CORRESPONDENT)

FEWER MEDICAL GRADUATIONS

THE report of Vienna University for 1933-34 shows for the first time since the war a distinct and constant fall in the number of students qualifying for the M.D. In 1913-14 the number of female and male students promoted to that degree was 385. When peace returned there was a rush of students whose studies had been interrupted and the figure went up to 521 in 1920, and rose steadily to 743 in 1924-25. After this, for quite a while it remained fairly stationary at about 600. In 1932-33 it again reached 521, and in the following year 442. According to calculations the final figure for 1934-35 will not exceed 420. But already an increase in the number of medical students has been announced again this winter term, for over 1500 have applied for admission to the courses. This is somewhat unexpected, for the lowering of the practitioner's income and general standard of life is so vividly manifest that one would have thought young men would be very unwilling to take up this profession. The only explanation one can think of is that the outlook is just as bad in all the other "intellectual" occupations, and that many a youth, thinking that times may change before he is through with his studies, goes in for medicine because nothing better opens before him in this country.

MARRIAGE AND PROGENY IN AUSTRIA

The Vienna board of health publishes some interesting statistics of the ages of men and women at marriage. A period of ten years has been chosen for fair comparison, and it is found that of all the men married during that period only 0.1 per cent. were under twenty; the same percentage of girls (0.1) were under sixteen and 6 per cent. were under twenty. In the age-group 20-25 we find 8 per cent. of the male partners and 25 per cent. of the females. The next five-year age-group, 25-30, shows nearly 50 per cent. of males and 40 per cent. females. Thus the majority of the population marry before they pass the thirtieth year of life, and the most favoured age is 25-30 for both sexes. After this the frequency of marriage quickly diminishes, for we find only 1.5 per cent. of men marrying between fifty and sixty and only 0.7 per cent. above the latter age. With the women, the figures were: 0.5 per cent. married

between fifty and sixty, 0.2 per cent. between sixty and seventy, and less than 0.1 per cent. after that. As a rule there is a difference of about five years between the ages of the bride and bridegroom in the favoured periods of marriage: 65 per cent. of all brides belonged to the age-group 20-30, and just as many men in the age of 25-35. Within the last five years the average marriage age has gone up, especially in the rural districts, where as a rule the couples are mostly older than in towns. This is perhaps due to the feeling of the rural population that there is nothing blameworthy in a young woman having an illegitimate child. The parents are in no hurry to marry, and indeed may later marry other partners, no blame being attached to the woman.

The Board of Health's report also gives information about the relative age of parents and children. Of all children 45 per cent. were born within the first ten years of matrimony, and 10 per cent. within the first three years. In 5 per cent. of the births the mother was over forty (no figure is given here for the fathers' age). About 1.5 per cent. of the children had fathers over fifty (the age of the mothers is not stated). It is interesting that 0.5 per cent. of the births took place twenty years or longer after the marriage. The oldest mother within the period of observation was 49½ at the time of her baby's birth, the oldest (supposed) father 72. Altogether the number of couples without children is growing rapidly and alarmingly in the towns, as everywhere in Europe. The decline of the births is over 50 per cent. in the last decade. It may be added here that the number of illegitimate births declined only by 15 per cent. so that relatively these are going up.

DEATH OF PROF. PAUL

A few days ago Dr. Gustav Paul, formerly director of the Federal Vaccination Institute, died at the age of 76. He was a native of Prague (then an Austrian city), and soon after his graduation was appointed assistant at the Medico-forensic Institute there. He then served in the public health department of the Ministry of the Interior, and in 1895 took over the charge of the new institute in Vienna for producing vaccination lymph. He was the discoverer of the corneal test for the early diagnosis of small-pox, and the modern equipment of the institute and its excellent organisation are entirely due to him. He also originated the therapeutic use of lymph for cutaneous therapy of chronic rheumatism, which is much used in Central Europe.

NEW HOSPITAL FOR ILFORD.—The Ilford council have accepted a tender from the Essex county council for the site of the old Ilford pumping station on which a new hospital of from 300 to 500 beds is to be built. The new hospital is intended to serve Barking and Dagenham, leaving the King George Hospital to provide for the northern area.

KING EDWARD VII. HOSPITAL, WINDSOR.—This hospital is starting a contributory scheme, to which members are to contribute a shilling a week and in return receive a sum not exceeding £28 a year in any twelve months towards the cost of hospital or nursing-home treatment for themselves or for their wholly dependent relatives. So long as accommodation is available they will be received at the King Edward VII. Hospital, in the private wards, but if this is not possible they will be able to make arrangements with another hospital or nursing-home. Applicants over sixty years of age will not be admitted, and the scheme does not provide for treatment of any notifiable disease, or for maternity or chronic cases.

PANEL AND CONTRACT PRACTICE

Group Practice in America

THE problems of medical practice in America appear to resolve themselves into two: (1) How can medical care be made more efficient and free from fee-splitting and other stigmata of commercialism? (2) How can such care, with adequate remuneration for the doctors giving it, be brought within the economic resources of the poorer members of the community? For the solution of the first problem Dr. Hugh Cabot in his recent book¹ favours an extension of group practice, which is now increasing in America. The first group, and of course the most outstanding, is the Mayo Clinic, which began in 1887, and there are now about 150 groups covering a very wide area. The group includes general practitioners and specialists with laboratory aids working as a medical and financial unit, the fees being paid not to the individual doctors but to the group. There is a growing tendency to extend the facilities afforded by the group to isolated practitioners in country districts, and so enlarge the group's area of influence. The group is in fact an example of evolution by differentiation and integration.

The second problem presents, perhaps, more formidable difficulties. Compulsory health insurance has been suggested as a solution, but Dr. Cabot, though alive to the advantages secured in Europe, and especially in this country, by this measure, is doubtful whether it would succeed in America. Fifteen years' experience of prohibition does not encourage him to view with approval any further attempts to impose compulsion on a large scale on the American people. Moreover, he attributes the success of the British health insurance system largely to the fact that it is administered by officers trained in public administration whose appointment and tenure do not depend on political influence, and he can see no adequate body of such administrators in his own country. He favours a development of voluntary insurance, particularly the insurance now offered by some of the groups, an extension of the medical care now provided by many large employers, and a definite assumption by the State of responsibility for the provision of medical care for the indigent—a responsibility which in most American communities is fulfilled very imperfectly or not at all. He feels strongly that something effective ought to be done, and dissents from the view apparently taken by "organised medicine" in America—the Christian Science view that the difficulties of providing adequate medical care are imaginary, and that the doctors may safely, in the words of Mr. Dooley, "turn the job over to Destiny."

In other respects too Dr. Cabot's book may well be studied by all who wish to come to a right understanding on the proper relation of doctor and patient in a modern community. Dr. Cabot is well known in this country, for during the late war he commanded a British base hospital. His recollections go back to the last decade of the last century, the heyday of the family doctor, when people lived in smaller communities, where the local doctors knew every member of the families they attended and acquired a fund of information on family characteristics that was of great help in diagnosis, prognosis, and treatment. He tells how some 35 years ago he assisted at a consultation attended by three Harvard pro-

fessors on a case of pneumonia. When the professors after mature consideration had arrived at a favourable prognosis it occurred to one of them to ask the views of the family doctor. "He remarked tersely that the patient was a Jones before she married; that Joneses who showed abdominal distension on the fourth or fifth day of pneumonia died; and that she would die within the week. She did." But such intimate knowledge of family peculiarities has, Dr. Cabot thinks, become practically impossible in these days with the rapid shifting of population and the increasing reliance of the public on specialist services. In America specialism is far more developed than in this country; in some large cities over 60 per cent. of the practitioners are engaged in some form of special practice.

In certain quarters this development is deplored as undesirable and unnecessary. The American Medical Association have apparently accepted the proposition "that more than 80 per cent. of all the ailments for which people seek medical aid can be treated most cheaply and most satisfactorily by a family physician with what he can carry in a hand-bag." From this proposition, or dogma as he calls it, Dr. Cabot dissents; it seem to him to clothe the overworked general practitioner with powers beyond the capacity of the human mind. He thinks that the immense advances in knowledge and technique of the last 20 years have made specialist services necessary over a very wide field, which is likely to expand with further advances. He is, however, aware of the evils of specialism under commercialised conditions of practice, one of the worst being fee-splitting, which, it appears, is prevalent in some parts of America. Dr. Cabot tells of a questionnaire on the subject addressed to 105 doctors, not members of the local medical society, of whom 57 replied that they were in favour of fee-splitting, and 48 that they were against it. He thinks the practice is increasing and that the profession must either destroy it or be content to be destroyed by it.

Conflicting Tribunals

A case noted under this heading (Oct. 19th, p. 920) has had a sequel in the Courts when an action by the father of the deceased girl against the insurance practitioner concerned was heard. The case for the plaintiff ran into part of two days, but the judge stopped the case without calling on the defence as no cause of action had been disclosed and he was satisfied there was no cause for complaint against the doctor. The facts of the case were simple. At 11.30 P.M. on a certain Friday the insured person was suffering with acute pains in her stomach. The pains and vomiting became worse and the services of the doctor were sought some time after midnight. The doctor did not visit the patient but gave the father a small bottle of medicine, prescribing the dose, and indicating that the girl should be seen on the following morning. By 7 A.M. the girl was definitely worse and the doctor was again called. On this occasion he examined the girl and telephoned for an ambulance to take her to hospital where an immediate operation was performed. She died early on the following day, the cause of death being (a) heart failure due to toxæmia, (b) general peritonitis due to (c) perforated duodenal ulcer. The doctor's statement was that he had treated the girl for indigestion and severe constipation a few months previously and thought it was quite possible that she was

¹ The Doctor's Bill. By Hugh Cabot, C.M.G., M.D., a senior consulting surgeon in the Mayo Clinic. New York: Columbia University Press. 1935. Pp. 313. 15s.

suffering from a similar attack. The father did not in any way convey to him the impression that his daughter was seriously ill, and appeared quite satisfied when he left the house with the medicine. According to the doctor he told the father that he would call and see the patient early on the following morning.

On and Off the Medical List

An insurance practitioner whose name was removed from the medical list of an insurance committee as from a date in 1924 now desires to secure readmission to the list in another area. He has applied to the Minister of Health for the restoration of his name, and in accordance with custom the Minister has invited the views of the insurance and panel committees before he accedes. The doctor has produced testimonials on his behalf from medical practitioners who speak well of his conduct during the past few years and express the opinion that he can be relied upon not to repeat conduct of the kind which led to his removal from the list. Both committees have decided to raise no objection, but the insurance committee pointed out quite properly that notwithstanding it is eleven years since the name was removed from the list they do not regard the mere efflux of time as a sufficient reason for permission to rejoin.

Any doctor has a right to the inclusion of his name in the list subject to his accepting service under the terms in force; in the case of chemists the committee are required to consult the pharma-

ceutical committee before including their names. It sometimes happens that applications for inclusion in the medical list are made by doctors who clearly cannot comply with the terms of service, and insurance committees are sometimes a little embarrassed in view of the fact that they have no right to refuse such applications. For instance, the Kent committee have just considered an application for inclusion in their list of a doctor whose surgery is situated in the heart of London. In applying to Kent he states that the districts in which he undertakes to visit insured persons are contained within a radius of two miles of his address in London, and as this radius does not include any part of the county of Kent the committee take the view that the application is not one to which they can accede and they have informed the doctor accordingly.

Gin

A Kentish doctor who was surcharged 10d. for the supply of 1 oz. of gin in mixture to an insured person has appealed against the decision. In entering her appeal she submitted that the mixture supplied is a recognised formula in the treatment of insomnia in cases of pulmonary tuberculosis. The insurance committee have informed the panel committee that in their view the order for gin was not necessary, inasmuch as it was open to the doctor to order an official preparation which would have produced a similar effect.

PUBLIC HEALTH

Puerperal Pyrexia

THE decision taken nearly ten years ago to make puerperal pyrexia compulsorily notifiable was bound to bring several administrative problems in its train. For the first time a symptom rather than a disease was included in the list of conditions which must be notified to the medical officer of health, and this has not yet been fully realised by many practitioners. The definition of puerperal pyrexia as contained in the P.H. (Notification of Puerperal Fever and Puerperal Pyrexia) Regulations, 1926, is quite clear and cannot be too often emphasised; it is—

"any condition (other than puerperal fever) occurring in a woman within 21 days after childbirth or miscarriage in which a temperature of 100.4° F. or more has been sustained during a period of 24 hours or has recurred during that period."

The practitioner is not required to make a diagnosis as to the cause of the fever; the fever by itself renders the case notifiable.

The question is repeatedly asked: is notification intended to cover the whole period of pregnancy? It seems clear from the definition given above that it does so, since the term "miscarriage" is not limited to any stage of pregnancy. The question has not been decided by any legal ruling, but it is understood that the Ministry of Health has expressed the opinion that it is desirable on medical grounds that notification should not be limited to cases of fever occurring after the birth of viable children but should also include infection subsequent to abortion and miscarriage. This construction of the regulation should be widely known.

To whom should notification be made? The rules governing this were altered somewhat by the amending regulations of 1928, in which the original notification to the medical officer of health of the area "within which the place of residence of the

patient is situate" was changed to "within which (the notifying practitioner) is attending such woman." This was done in order to correct the anomaly of cases being primarily notified to the medical officers of districts far away from where the confinement took place and infection occurred, and it covers such cases as the large group who are confined in central institutions out of the area in which they reside and those who "go home to mother" for their confinement. An exception was made in the case of London, where cases arising in a hospital must be notified to the medical officer of the borough from which the patient was brought into the hospital. This was done in order to abolish the previously existing discrepancy between notification of puerperal fever and puerperal pyrexia. Cases which are brought into a district for treatment in a hospital after notification elsewhere, like all other notifiable infectious diseases, should not be re-notified or included in the returns of the district (R.G.'s Circular No. 51, 1934).

Lastly, on whom does the responsibility for providing assistance in diagnosis and treatment rest? The answer is (M. of H. Circular No. 722, 1926) that the authority for maternity and child welfare of the district in which the case occurs is clearly in the best position to render such assistance, either directly or by arrangement, and the M.O.H. of an area which is not an authority for maternity and child welfare who receives a notification of puerperal fever or pyrexia is required to forward it within 24 hours to the county medical officer.

FIFE AND KINROSS JOINT ASYLUM, CUPAR.—Plans for an extension to this hospital which will cost £42,400 have been accepted by the asylum committee. The extension provides for a main corridor with seven ward blocks.

CORRESPONDENCE

THE INDEPENDENT MIDWIFE

To the Editor of THE LANCET

SIR,—All who are interested in the practice of midwifery will thank you for the informed and sympathetic leading article on the independent midwife which was published in your last issue. The grave economic difficulties of the independent midwife were emphasised in the report of the Joint Council, to which reference is made in your article, and the data given by Lady Forber in her Fynes-Clinton lecture furnish convincing proof of the severity of these difficulties. Notwithstanding the drive to hospital which has been going on in recent years, domiciliary midwifery is still, and will probably remain, the basis upon which an organised maternity service must be built up. Midwives attend approximately 60 per cent. of all confinements in this country, and their work is done almost exclusively in the homes of the industrial classes. They therefore constitute a highly important unit of the maternity service as it exists at present, and it is an interest, not only of the medical profession, but also of the public, that their work should attain a high degree of efficiency. Midwives who are working under conditions of economic hardship, or even as we now know of actual privation, cannot give of their best, and it is unquestionable that suitable measures to improve their lot are long overdue.

Recent utterances of the Minister of Health suggest that the Government intend to establish a salaried service of midwives; this will provide full employment, adequate emoluments, and security for those who enter it. Unfortunately the number of midwives practising is considerably in excess of the number actually required; consequently a choice will have to be made and those who do not enter the salaried service will, if they remain in practice, be exposed to the existing economic difficulties. The problem of how to improve the lot of this remainder is both complex and difficult. It should, however, be borne in mind that not all of them are entirely dependent for a livelihood on what they earn as midwives. An unspecified proportion of them are "part-time" midwives, who have other means of support, and sometimes follow other occupations when not actually engaged in maternity work. There is much to be said for the view that a midwife's work should always be a "whole-time" job; she will not do her best unless she is in it heart and soul, nor can she maintain her professional efficiency if there are long or frequent intervals in which her attention is turned to other pursuits. There is reason to believe that many part-time midwives turn to other occupations because they cannot get enough cases to earn a livelihood, but many others are part-time midwives from choice, and take cases only as a means of earning a little extra money when required.

The liberty which midwives now possess to regard midwifery as a subsidiary interest, and not as a serious profession which demands their whole attention, is an anomaly which is detrimental to the interests both of the public and of themselves. It may be difficult to end this anomaly at a stroke, but it is inconceivable that it should remain as a permanent feature of our midwifery system.

I am, Sir, yours faithfully,

T. WATTS EDEN.

London, W., Nov. 4th.

To the Editor of THE LANCET

SIR,—The Midwives' Institute has agreed in principle with the establishment of a service of salaried midwives, but it has always realised that, if such a service is to be successful, the competent midwives now in practice must be retained so far as is possible. The returns for the questionnaire sent by the Institute to independent midwives, and ably reviewed by Lady Forber in a preliminary survey at the Fynes-Clinton lecture which you discuss in your leading article of Nov. 2nd, do in fact show that the middle-aged private midwife is the stand-by of the mother, especially in urban areas, and as is well known her records are for the most part excellent.

It has to be recognised that until schemes can be devised to make recruitment to the midwifery service an attractive and permanent profession to young well-educated women, both by regulation of the number of entrants and the provision of a longer and better training, both expediency and justice will be best served by making full use of the most experienced of the present-day midwives. It also needs to be realised that the midwife who is employed as a full-time worker requires adequate pay; her expenses which must be incurred in connexion with her profession are considerable and include the provision of uniform, apparatus, telephone, and suitable domestic help. The Institute is making further detailed inquiry into the cost of these items, but it is certain that the midwife's salary should not, on the above grounds alone, be in any case less than that now given to health visitors; and further, in assessing salaries above the minimum, the greater responsibility of the midwife should be taken into account.

The Midwives' Institute, although it holds fast to the conviction that the midwife must always hold full personal responsibility for her own part of the work, knows well that safe pregnancy and parturition require the close coöperation of doctors and midwives.

I am, Sir, yours faithfully,

E. M. PYE,

President, the Midwives' Institute.

57, Lower Belgrave-street, S.W., Nov. 4th.

THE TOXÆMIA OF BURNS

To the Editor of THE LANCET

SIR,—Patients who die during the first four days following the infliction of a severe burn are generally debited to that nebulous and all-pervading entity known as "toxæmia," the Atlas or Hercules of surgery and midwifery, on whose broad shoulders is placed responsibility for nearly every catastrophe not clearly due to a known deadly agent. With the adoption of the tannic-acid treatment of burns by E. C. Davidson, of Detroit, in 1925, the percentage of deaths in the stage of "acute toxæmia" fell significantly: an improvement ascribed, quite justifiably, to the coagulating effect of tannic acid on soluble protein, resulting in less absorption of some toxic and supposedly albuminous substance dissolved and possibly denatured. It is stated in the Medical Research Council's special report (No. 141, p. 10): "No antibodies (to these toxic substances) are produced." Sepsis, in these cases, is yet to be controlled, as the same report admits in the con-

cluding paragraph: "Further therapeutic advances will follow the lines of simplifying and shortening the methods for inducing coagulation, and of more efficiently preventing and controlling sepsis." In the absence of sepsis, the M.R.C. authorities seem to imply, there can be no toxæmia due to bacteria; the first four days' sickness, they conclude, is too early for any possible bacterial action.

It occurred to me that a proportion of the cases dying of "acute toxæmia" during the four dangerous early days might be accounted for on the assumption that their symptoms were due to the absorption of staphylococcal toxin. This theory I have not yet had the opportunity of testing on any effective scale, but I think it worthy of consideration. One case of an adult whom I had treated for an independent condition with a long course of staphylococcal toxoid injections fell and was dragged while playing polo and sustained a very extensive graze, including the skin over nearly the whole of his back and shoulders. This healed without any signs of sepsis or toxic absorption—a most unusual result. More important, Prof. R. Cruickshank (Jour. Path. and Bact., Sept., 1935, p. 367) found *Streptococcus hæmolyticus* in the skin of half his burn cases on the second day; *Staphylococcus aureus* was also frequently present, and *Staph. albus* in 56 per cent. of cases on the first day. Staphylococcal toxin can be produced in the body very rapidly, and its effects may not be preceded by any display of "sepsis," as the Bundaberg disaster taught us. I suggest that every case of severe burn should receive intravenously, at the earliest possible moment, an injection of staphylococcal antitoxin amounting, for an adult of normal size, to at least 5000 international units. I believe it is the practice in some hospitals to give streptococcal antitoxin prophylactically; the staphylococcal antitoxin could be combined with this.

People constantly exposed to the risk of severe burns, by nature of their employment, could be treated prophylactically with a course of staphylococcal toxoid injections.

I am, Sir, yours faithfully,

FRANK MARSH.

BREATHING EXERCISES IN ASTHMA

To the Editor of THE LANCET

SIR,—My attention has just been called to an article by Dr. J. L. Livingstone in THE LANCET of Sept. 28th entitled the Value of Breathing Exercises in Asthma. I feel bound to add from first-hand knowledge some facts to his account. I was chairman of King's College Hospital from 1929 to 1933; as over a long period of years Miss Seyfang had effected complete and lasting cures for asthma for many of my relatives and friends by means of breathing exercises, and as she was perfectly willing, indeed anxious, to place the exercises that she had devised into a system after years of study and training at the disposal of the medical profession, I suggested to Dr. Livingstone that she should work in the Asthma Clinic at King's so that her methods could be observed and the results tabulated. This was arranged, and as a consequence Dr. Livingstone told me himself that he had never before seen anything to approach the successes obtained by the exercises. Unfortunately in arranging for their extension he took the view that no training was necessary in them for the giver. They were incorrectly given in con-

sequence, and as any failure would then have been attributed to Miss Seyfang's system she, with my approval and indeed at my advice, ceased to give her services. She had given them for nearly two years on a purely honorary basis and with undisputed success. Dr. Livingstone says in his article that the system of exercises used by Miss Seyfang "differed only in detail" from those already known. I cannot recall that any breathing exercises for asthma were successfully used at King's before her advent, and in any case surely that remark is equivalent to a practitioner saying that he knew that a certain cure was good for a certain disease but that he did not know, in detail, what the prescription should be.

Miss Seyfang has never complained of the ungenerous treatment she received, but has continued her extremely successful work in her own clinic, and has earned the lasting gratitude of all who have been to her.

I am, Sir, yours faithfully,

31, Kensington-square, W., Oct. 31st.

GORELL.

QUININE AMBLYOPIA

To the Editor of THE LANCET

SIR,—As cases of quinine amblyopia are rare in this country, the enclosed picture of the left fundus of a patient's eye may be of interest to some of your readers. The disc is atrophic, and some of the arteries have become thread-like, while the visual fields were contracted peripherally. In spite of these changes, after a few injections of strychnine, the patient got full vision with glasses for a small amount of myopia.

The patient was seen for Dr. G. Hume (who was away), and the history was that after being away from white people for two years, doing administrative work among natives in Africa, he developed obsessions and, being invalided home, tried to end his life by taking 60 grains of quinine. He went blind and deaf, but when I saw him sight and hearing had somewhat recovered. He was 26 years of age. The cerebro-spinal fluid was normal, but the blood gave a very faint Wassermann reaction, which was not confirmed later. As the fundus, visual fields, and history are typical of quinine poisoning, and there were neither history nor signs of syphilis, that can be excluded.

My friends in the tropics tell me that 15 grains of quinine sometimes make patients uncomfortable. My chemist-patients and friends here tell me that women try it as an abortifacient, but generally get frightened and give it up on the first signs of giddiness, headache, deafness, or interference with their sight—symptoms which may be produced by doses of 15-30 grains.

I am, Sir, yours faithfully

Harley-street, W., Oct. 29th.

SYDNEY TIBBLES.

ATTITUDE OF SURGERY TO HÆMATEMESIS

To the Editor of THE LANCET

SIR,—Correspondence on Mr. Gordon-Taylor's address has been so much taken up with discussion of Prof. Finsterer's statistics that I hope I may be allowed to bring back attention to those the author gave from his own practice. Mr. Gordon-Taylor's addresses are always stimulating and refreshing—stimulating in their surgical ideas and refreshing in their phraseology. Statistics from his pen are not antagonistic things inviting criticism, but they are none the less worthy of consideration.

We read that for the period 1910-24 he operated on 22 cases of hæmatemesis from peptic ulcer with 2 deaths; he makes it clear that in this period the cases on which he operated were mostly dealt with in the first twenty-four hours. During the period 1924-26 he operated on 10 cases with 4 deaths, but these were mostly later cases. A spirit of self-criticism and disinclination to operate induced an abstinence from active surgery for five years, and during this time the mortality of acute hæmatemesis from chronic ulcer in cases which he saw was enormous. We read further that the mortality of cases of hæmatemesis from chronic ulcer of the stomach or duodenum treated medically at the Middlesex Hospital from 1924 to 1933 inclusive, in which a second large hæmorrhage occurred, was no less than 78 per cent., and that with each successive bleeding the death-rate mounted higher. A return to active surgery was obviously indicated, for we may take it that the treatment as carried out by the physicians of the Middlesex Hospital left nothing to be desired, and it is worthy of note that the medical department of this hospital is responsible for one of the most recent advances in treatment—the adoption of the blood-drip transfusion.

The question as to the type of operation to be performed in any particular instance is perhaps more debatable. In assessing Prof. Finsterer's figures on gastrectomy for hæmatemesis it must not be forgotten that this distinguished surgeon has perhaps the most extensive experience in the world of the operation of gastrectomy, and on his own confession has performed the operation more frequently than appendicectomy—an experience which must be unique. Should it become customary for British surgeons to perform a partial resection in every case of acute hæmatemesis due to peptic ulcer the result might be disastrous. Gastrectomy seems to be an unnecessarily severe operation for a desperately ill patient, granting even the facilities of blood transfusion and up-to-date institutional equipment. I do not wish to convey that Mr. Gordon-Taylor is a strong protagonist of gastrectomy in these cases, for he expressly states in his address that the technique he adopts varies in different cases and is dictated by various considerations.

Dr. Aitken's request that surgery should be restricted to the minimum of interference agrees with the teaching of Mr. James Sherrin at the London Hospital. Like Mr. Gordon-Taylor, Mr. Sherrin was a strong advocate of operation as soon as possible after the first hæmorrhage, but he was usually content with ligation of arteries, or, if need be, exposure of the ulcer and direct control of the bleeding point; resection where necessary was confined to the ulcerated area. Prof. Finsterer is opposed to the ligation of the gastroduodenal artery in cases of hæmorrhage from a posterior ulcer of the duodenum, for he believes that in about 4 per cent. of cases the anastomosis around the head of the pancreas is

not adequate. It seems doubtful whether this is a serious objection when we consider that in a proportion of cases of duodenectomy there must be material interference with this artery in the course of the operation.—I am, Sir, yours faithfully,

Harley-street, W., Nov. 5th.

MICHAEL SMYTH.

CHRONIC NASAL SINUSITIS AND MENTAL DISORDER

To the Editor of THE LANCET

SIR,—The review of my book in your journal of Sept. 21st states (p. 669) that "the finding of sinusitis in patients who died in mental hospitals, often after many years of institutional life, cannot be taken as etiologically significant in the absence of control data." As this statement might be taken to imply that sinusitis develops as the result of residence in mental hospitals, I have collected the data relating to 572 consecutive post-mortems. These show:

(1) That the amount of sinusitis in mental hospital patients actually decreases at a steady rate during the time they are in hospital, many persons after more than 30 years' stay in hospital having sinuses of perfectly normal appearance.

(2) That chronic sinusitis has no special relationship to age (being found in infants a few weeks old), since patients over 80 may have sinuses of quite normal appearance.

(A)			(B)		
Time in hospital.	Cases.	Sinusitis. Per cent.	Ages in years.	Cases.	Sinusitis. Per cent.
1 month or less..	91	65	0-20 ..	10	70
1-12 months ..	122	62	20-30 ..	49	61
1-5 years ..	152	57	30-40 ..	87	68
5-10 ..	74	56	40-50 ..	128	56
10-20 ..	80	56	50-60 ..	131	52
20-30 ..	37	57	60-70 ..	105	55
Over 30 ..	16	44	70-80 ..	49	65
			Over 80 ..	10	70
—	572	—	—	572	—

In a consideration of the figures supplied one must avoid the error of relating the actual sinusitis to the mental disorder; since it is only special complications arising from the sinusitis, such as a periodic bacteriæmia, or a continued local spread of toxins towards the brain, which are of importance in this connexion. Such complications are etiologically related to pathological brain changes which cause local defect of function; in some cases this is shown by abnormal behaviour or bizarre mental phenomena. Histological spreading of organisms from a nasal sinusitis has been demonstrated in some mental patients, and it is probable that clinical investigation will show that a previously unsuspected large proportion of cases of chronic nasal sinusitis sooner or later show abnormal mental symptoms or behaviour.

Exactly however what is demanded or meant by "control data" is not clear.

I am, Sir, yours faithfully,

F. A. PICKWORTH.

City and University of Birmingham Joint Board of Research for Mental Disease, Birmingham, Oct. 28th.

** The statement implied nothing but the need for controlled data. These would consist of an adequate number of observations on the frequency of nasal sinusitis, investigated and determined by Dr. Pickworth's procedure, in persons mentally healthy but living under conditions as similar as possible to those of Dr. Pickworth's mental hospital patients. The substitution of "pyorrhœa" for "sinusitis" may serve to illustrate the need for such controlled data.—Ed. L.

MEDICAL GRADUATES FOR PARLIAMENT

SEVENTEEN members of the late House of Commons held a medical qualification, two of whom—Dr. G. B. Hillman and Dr. Joseph Hunter—died during the session. Of the remainder, two have been re-elected without opposition.

Name.	Constituency.	Party.
Prof. T. Sinclair	.. Queen's University, C. Belfast.	
Dr. J. H. Williams	.. Carmarthen (Llanely) Lab.	

Thirteen others are standing for re-election along with fourteen new candidates, seven of whom have contested Parliamentary seats before. In the following list those who sat in the last Parliament are indicated by a dagger sign, those who have sat in any previous Parliament by a double dagger, and those who have stood before without success by an asterisk.

LONDON BOROUGHES

Candidate.	Constituency.	Party
†Dr. Alfred Salter	.. Bermondsey (West)	.. Lab.
*Dr. C. R. Cooke-Taylor	.. Camberwell (Dulwich)	.. L.

BRIEF PERSONAL NOTES

Right Hon. CHRISTOPHER ADDISON, M.D. Lond., F.R.C.S. Eng., who was the first Minister of Health (1919-21) and Minister of Agriculture in the Government of 1929, was at one time professor of anatomy at University College, Sheffield. He has also been Hunterian professor at the Royal College of Surgeons, and lecturer on anatomy at St. Bartholomew's Hospital.

RICHARD A. BARLOW, B.Sc., M.B., F.R.F.P.S. Glasg., who is standing for Edinburgh, Central, is senior partner in a general practice at Rochdale. He qualified at Glasgow University in 1913 and has held appointments in Glasgow and Cape Town.

C. W. BROOK, M.R.C.S. Eng., qualified from St. Bartholomew's Hospital in 1925. He has for the last four years represented Southwark North on the London County Council in the Labour interest and has been chairman of the committee for welfare of the blind. He stood unsuccessfully for Wandsworth in 1929.

J. DOUGLAS COOKE, M.B. Melb., F.R.C.S. Eng., qualified in Australia and was resident at the London Hospital. He practised for twenty years at Stanmore and contested Peckham unsuccessfully, before gaining the seat at Hammersmith (South).

C. R. COOKE-TAYLOR, M.R.C.S., D.P.M., took honours in jurisprudence at Oxford and was called to the bar in 1910. He qualified from University College Hospital in 1927. He is visiting physician to the British Hospital for Nervous and Mental Disorders, and psychologist to the Ex-Service Welfare Society. This is the eighth time he has contested Dulwich; he stood for Holborn in 1910. He is hon. treasurer of the University of London Liberal Association.

Right Hon. WALTER E. ELLIOT, M.C., M.B., D.Sc. Glasg., LL.D. Aberd., who first entered Parliament in 1918, was Under Secretary of Health for Scotland in 1923. He has been Minister of Agriculture and Fisheries since Sept., 1932.

SIR FRANCIS FREMANTLE, O.B.E., M.D., M.Ch. Oxon., F.R.C.S. Eng., F.R.C.P. Lond., has sat in six Parliaments as member for the St. Albans division, and has been chairman of the Parliamentary medical committee. He was for fifteen years county medical officer of health for Herts, and is deputy lieutenant and a justice of the peace.

SIR ERNEST GRAHAM-LITTLE, B.A., Univ. Cape of Good Hope, M.D., F.R.C.P. Lond., who has represented the University of London since 1924, is in charge of the skin department at St. Mary's Hospital, London. He has been a member of the University senate since 1905 and has long been chairman of the external council. In the last Parliament he was chairman of the road accidents Parliamentary group.

L. HADEN GUEST, M.C., M.R.C.S., was member for North Southwark in 1923 and became Parliamentary private secretary to the Minister of Health. He has been school medical officer, consulting physician to St. George's school clinic, Blackfriars, and a member of the London County Council.

HENRY C. HASLAM, M.A., M.B., Sc.D. Camb., has been member for the Horncastle division of Lincoln since 1924. Before that he spent twenty years in biochemical research at Cambridge, holding the John Lucas Walker studentship.

SOMERVILLE HASTINGS, M.S. Lond., F.R.C.S. Eng., who is surgeon and lecturer to the ear and throat department of the Middlesex Hospital, is contesting Reading for the fifth time. He sat for Reading in two previous sessions but was defeated by Dr. Howitt at the last election; in 1923-24 he was private Parliamentary secretary to the President of the Board of Education. He represents Stepney (Mile End) on the London County Council and is chairman of the hospitals and medical services committee. He is president of the Socialist Medical Association.

A. B. HOWITT, C.V.O., M.D. Camb., was Epsom scholar at St. Thomas's Hospital, qualifying in 1906, and holding a number of hospital appointments, including that of resident medical officer at St. Thomas's Home. This is the fourth time he has stood for Parliament. He contested Preston in the general election of 1929 and again two months later at a by-election. In the 1931 election he defeated Mr. Somerville Hastings at

Reading and he is standing again for the same constituency. He has been secretary to the Parliamentary medical committee for the past four years.

Sir HENRY JACKSON, Bart., M.A. Camb., B.Sc. Lond., M.B. Edin., who was formerly senior tutor and lecturer at Downing College, Cambridge, and in general practice on Putney Hill, was Mayor of Wandsworth from 1921-24. He is treasurer of the Bolingbroke Hospital, vice-chairman of the London voluntary hospitals central committee, and president of London University Conservative Association. He has represented Wandsworth (Central) in two previous Parliaments.

ELIZABETH JACOBS, M.R.C.S. Eng., who is contesting St. Marylebone, qualified from St. Mary's Hospital in 1925 and is in general practice with her husband in Maida Vale.

SANTO W. JEGER, M.R.C.S. Eng., who has a general practice in East London, qualified from the London Hospital in 1923. He was Mayor of Shoreditch in 1929 and has been for six years chairman of the public health committee. Since 1931 he has represented Shoreditch in the Labour interest on the London County Council; he is a member of the hospitals and medical services committee and vice-chairman of the parliamentary committee. Dr. Jeger is chairman of the Heatherwood Hospital and was one of the founders of the Socialist Medical Association.

D. McINTOSH JOHNSON, M.B. Camb., who is standing for Bury, qualified from St. Bartholomew's Hospital in 1926 and after holding house appointments took charge of the Harrington Hospital (International Grenfell Association) in Labrador. He is a barrister-at-law and is now in general practice at Thornton Heath, Surrey.

J. W. LEECH, M.D., D.Ch. Durh., F.R.C.S. Edin., who was Sheriff of Newcastle-on-Tyne, 1930-31, and Lord Mayor 1932-33, is consulting surgeon to the Royal Victoria Infirmary. He is ex-president of the Newcastle Clinical Society and of Durham University Medical Graduates Association, and a county J.P. He represented Newcastle (West) in the last Parliament.

R. A. LYSTER, B.Sc. Lond., M.D., D.P.H. Birm., who contested the Winchester division of Hants in the general elections of 1929 and 1931, was county medical officer of health for Hampshire from 1908 to 1929. He has been president of the Society of Medical Officers of Health and of the Association of County Medical Officers. He has just been returned for the third time as Labour member of the Bournemouth town council.

PERCY McDougall, B.Sc. Lond., M.B. Vict., who is standing as an independent candidate for the Rusholme division of Manchester, contested the same seat at a by-election in November, 1933. He qualified at Manchester in 1894, was house surgeon at the Royal Infirmary, and has been 34 years in general practice in Fallowfield. He finds in land monopoly the great disease in the body politic.

JOHN H. MORRIS-JONES, M.C., L.R.C.P. Edin., who was returned for Denbigh unopposed at the last general election, was in general practice there for twenty years and is now senior consulting physician to the West Denbigh Hospital. For three years he has been a Government whip.

W. J. O'DONOVAN, O.B.E., M.D., M.R.C.P. Lond., is physician to the dermatological department and lecturer on dermatology at the London Hospital, which is in the centre of his constituency. In and out of the House of Commons he has made a special effort to represent the medical point of view. He is chairman of the University of London Conservative Association.

ALFRED SALTER, M.D. Lond., D.P.H., has sat for his constituency continuously since 1922. He was

chairman of the medical committee during the 1929 Parliament. He is a J.P. for the county of London and an alderman of Bermondsey Borough Council. He retired from general practice in Bermondsey in 1929 and is now engaged in consultant work chiefly in connexion with claims of injured workmen under the Workmen's Compensation Acts.

SAMUEL SEGAL, B.A. Oxon., M.R.C.S. Eng., was exhibitor at Jesus College, Oxford, and qualified from the Westminster Hospital in 1927, after which he held resident appointments there. Since 1929 he has been in general practice in north-west London.

THOMAS SINCLAIR, C.B., M.D., M.Ch. R.U.I., F.R.C.S. Eng., who has been returned unopposed for Queen's University, Belfast, holds the chair of surgery in the university, and is consulting surgeon to the Belfast Royal and other hospitals. He is a member of the General Medical Council and a senator for Northern Ireland.

EDITH C. SUMMERSKILL, M.R.C.S. Eng., who qualified from Charing Cross Hospital in 1924, is medical director of the birth control clinic at Wood Green, and member of council of the National Birth Control Association.

GEORGE DE SWIETECHOWSKI, M.D. Munich, M.R.C.S. Eng., who is a general practitioner in Paddington, was born in Poland and qualified in this country in 1912. During the war he was civil medical officer to the 4th London General Hospital. He was the first president of the Paddington Medical Society, and one of the founders of the London public medical service. He is chairman of executive of the Medical Practitioners' Union and has represented Paddington for twelve years on the London Panel Committee.

WM. S. RUSSELL THOMAS, M.B. Camb., who is standing for the central division of Aberdeen and Kincardineshire, qualified from Guy's Hospital in 1919 and after holding resident appointments there and elsewhere settled in general practice at Warlingham, Surrey. In 1931 he contested Ilford without success. He is a barrister-at-law.

J. H. WILLIAMS, L.S.A., who qualified from the London Hospital in 1902, is partner with his son in general practice at Burry Port. He is a member of the Middle Temple, a justice of the peace, and chairman of the public health committee for the county of Carmarthen.

Sir JOHN WORTHINGTON, M.R.C.S. Eng., who is standing again for the Forest of Dean division of Gloucester, was Parliamentary private secretary to Mr. Ramsay MacDonald when Prime Minister. He comes of a medical family and qualified from the London Hospital in 1895.

LONDON MEDICAL SOCIETIES

At the opening of a new session we are again giving for the convenience of our readers the names of presidents and hon. secretaries of London medical societies, with the addresses at which they can be approached.

Royal Society of Medicine.—President: Dr. Robert Hutchison. Hon. secretaries: Dr. Anthony Feiling and Mr. G. T. Mullaly. (1, Wimpole-street, W.1.)

Medical Society of London.—President: Prof. G. E. Gask. Hon. secretaries: Mr. C. P. G. Wakeley and Dr. A. H. Douthwaite. (11, Chandos-street, W.1.)

Hunterian Society.—President: Dr. W. Brander. Hon. secretaries: Mr. M. Oldershaw and Mr. A. E. Porritt. (26, Upper Wimpole-street, W.1.)

Harveian Society.—President: Mr. L. E. C. Norbury. Hon. secretaries: Dr. A. D. Morris and Mr. John Hunter. (Hammersmith Hospital, Duane-road, W.12.)

Royal Society of Tropical Medicine and Hygiene.—President: Sir Arthur Bagshawe. Hon. secretaries: Dr.

C. M. Wenyon, F.R.S., and Dr. Hamilton Fairley. (Manson House, 26, Portland-place, W.1.)

Royal Medico-Psychological Association.—President: Dr. Reginald Worth. Hon. general secretary: Dr. Reginald Worth. (Springfield Mental Hospital, S.W.17.)
Society of Medical Officers of Health.—President: Dr. W. G. Savage. Executive secretary: Mr. G. L. C. Elliston. (1, Thornhaugh-street, W.C.1.)

Association of Industrial Medical Officers.—President: Dr. N. Howard Mummery. Hon. secretary: Dr. Donald Stewart. (I.C.I. Metals Ltd., Kynoch Works, Witton, Birmingham.)

Tuberculosis Association.—President: Dr. L. S. T. Burrell. Hon. secretary: Dr. F. R. G. Heaf. (Colindale Hospital, Hendon, N.W.9.)

British Institute of Radiology.—President: Dr. L. A. Rowden. Hon. secretaries: Dr. R. Boulton Myles and Mr. G. E. Bell, M.Sc. (32, Welbeck-street, W.1.)

Medico-Legal Society.—President: Mr. C. A. Mitchell, D.Sc. Hon. secretaries: Mr. Ernest Goddard and Dr. W. G. Barnard. (3, South-square, Gray's Inn, W.C.1.)

London Association of the Medical Women's Federation.—President: Dr. E. M. Pickard. Hon. secretary: Mrs. Philippa Martin. (40, Wimpole-street, W.1.)

Medical Society of Individual Psychology.—Chairman: Dr. C. M. Bevan-Brown. Hon. secretary: Dr. Alexander Baldie. (7, Warrington-gardens, Warwick-avenue, W.9.)

Society for the Study of Inebriety.—President: Dr. William Brown. Hon. secretary: Dr. T. N. Kelynack. (144, Harley-street, W.1.)

The Cancer Society.—President: Dr. A. C. Magian. Hon. secretary: Dr. D. F. Kennard. (225, Euston-road, N.W.1.)

London Jewish Hospital Medical Society.—President: Dr. D. N. Nabarro. Hon. general secretary: Dr. Max Sorsby. (London Jewish Hospital, Stepney Green, E.1.)

St. John's Hospital Dermatological Society.—President: Dr. J. E. M. Wigley. Hon. secretary: Dr. I. Muende. (49, Leicester-square, W.C.2.)

Chelsea Clinical Society.—President: Mr. H. Paxton Baylis. Hon. secretaries: Mr. A. Rugg-Gunn and Mr. Robert Cutler. (8, Lower Sloane-street, S.W.1.)

Hackney Medical Society.—President: Dr. A. J. Ambrose. Hon. secretary: Dr. H. Stark. (26, Stoke Newington Common, N.16.)

Hampstead Medical Society.—President: Dr. J. Alison Glover. Hon. secretaries: Dr. John Kennedy and Dr. T. J. Hollins. (13, Belsize-park, N.W.3.)

North London Medical and Chirurgical Society.—President: Mr. John Hunter. Hon. secretaries: Dr. W. E. Snell and Dr. J. W. Campbell Maxwell. (Royal Northern Hospital, N.7.)

North-West London Medical Society.—President: Sir Harold Gillies. Hon. secretary: Mr. Lionel Green. (127, Harley-street, W.1.)

Priory Medical Society.—Hon. secretary: Dr. J. Clark Wilson. (18, College-crescent, N.W.3.)

South-West London Medical Society.—President: Dr. R. J. Saunders. Hon. secretaries: Dr. E. G. Housden and Dr. A. W. Wells. (51, Longley-road, S.W.17.)

Paddington Medical Society.—President: Dr. Alexander Baldie. Hon. secretary: Dr. S. Crown. (81, Elgin-avenue, W.9.)

West London Medico-Chirurgical Society.—President: Dr. Bernard Myers. Hon. secretaries: Mr. James Kemble and Dr. W. K. McKinstry. (128, Harley-street, W.1.)

West Kent Medico-Chirurgical Society.—President: Dr. J. R. Wyllie. Hon. secretary: Dr. C. J. B. Buchan. (267, Baring-road, Grove Park, S.E.12.)

Surg. Lt.-Comdr. F. C. Bamford to *Maine*.
Surg. Lt. H. de B. Kempthorne to *Ramillies*.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. (D) H. P. Buchanan promoted to Surg. Lt.-Comdr. (D).
T. D. G. Wilson entered as Proby. Surg. Lt.

ROYAL ARMY MEDICAL CORPS

Majs. R. R. Thompson, M.C., and D. McVicker, M.C., retire on ret'd. pay.

Capt. H. N. Walker is placed on the half-pay list on account of ill-health.

Short Serv. Commissions.—Lts. to be Capts.: K. H. Clark, C. S. Gamble, J. A. D. Johnston, J. A. Scott, W. G. Greene, W. M. Oxley, O. R. L. L. Plunkett, R. H. Hunt, F. Williams, A. J. A. Gray, J. Reeve, G. M. Denning, H. H. Atkinson, J. O'Connell, and C. G. O'Driscoll.
Lt. (on prob.) A. Gleave is rest'd. to the estab.

REGULAR ARMY RESERVE OF OFFICERS

Capt. W. W. Phillips resigns his commn.

ARMY DENTAL CORPS

W. F. O'Carroll is granted a temp. commn. in the rank of Lt.

TERRITORIAL ARMY

Majs. C. P. Oliver and A. J. Chillingworth resign their commns.

Lts. H. S. H. Gilmer and E. D. Fitzpatrick to be Capts.

ROYAL AIR FORCE

Squadron Leader W. J. G. Walker to R.A.F. Station, Kenley, for duty as Medical Officer.

Flight Lt. H. Penman is promoted to the rank of Squadron Leader.

Flight Lt. G. H. J. Williams to No. 1 Armament Training Camp, Carfoss.

Dental Branch.—Flying Offr. A. Maben to R.A.F. Depot, Uxbridge.

INDIAN MEDICAL SERVICE

Capt. G. P. Charlewood is confirmed in his appt.
Indian Medical Department.—Capt. (Sen. Asst. Surg.) H. C. De Penning retires.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
OCT. 26TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2889; diphtheria, 1199; enteric fever, 27; acute pneumonia (primary or influenzal), 713; puerperal fever, 49; puerperal pyrexia, 112; cerebro-spinal fever, 8; acute poliomyelitis, 23; acute polio-encephalitis, 2; encephalitis lethargica, 3; dysentery, 15; ophthalmia neonatorum, 72. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Nov. 1st was 3112, which included: Scarlet fever, 1171; diphtheria, 1203; measles, 42; whooping-cough, 246; puerperal fever, 20 mothers (plus 10 babies); encephalitis lethargica, 277; poliomyelitis, 12. At St. Margaret's Hospital there were 20 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 13 (1) from measles, 2 (0) from scarlet fever, 2 (0) from whooping-cough, 32 (6) from diphtheria, 60 (14) from diarrhoea and enteritis under two years, and 46 (9) from influenza. The figures in parentheses are those for London itself.

Measles proved fatal in 5 cases at Manchester and 4 at Liverpool. Leeds reported the only deaths from whooping-cough. Warrington had 3 fatal cases of diphtheria. Portsmouth, Liverpool, Wallasey, each 2. Influenza is credited with 4 deaths at Manchester, no more than 2 in any other large town.

The number of stillbirths notified during the week was 275 (corresponding to a rate of 44 per 1000 births), including 36 in London.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Rear-Admiral G. L. Buckeridge, O.B.E., M.R.C.S., has been appointed Honorary Surgeon to the King from Sept. 22nd, 1935.

Surg. Rear-Admiral F. J. Gowans to *Drake* for R.N. Hosp., Plymouth, and as M.O. in charge.

Surg. Comdrs. M. Brown to *Victory* for R.N. Hosp., Haslar; and H. H. Babington to *Pembroke* for R.N.B.

MEDICAL NEWS

University of Cambridge

On Nov. 2nd Dr. John A. Ryle, regius professor of physic in the University, received the honorary degree of doctor of medicine. In presenting him the public orator said:

Adest vir eximius, qui, nepos Theologi nostri inter patres dilecti et ad episcopatum vocati, nomen antiquum ad Universitatem nostram reportat. Sed aliis se dedit studiis maluitque "scire potestates herbarum usumque medendi," et diu artem agitavit nec illam mutam nec ipse inglorius. *Agavephias* enim callidus investigator, stilo quoque insignis, quinque morbi typos vult distinguere, sive sedendo quis, ut Thescus, sive imaginando ventri suo contumelias iniuriasque imponit, sive cibis toxicato—sed quid plura? Morbos vestros nolo timoribus aggravare. Adest, a Rege nostro electus, ut alumnis nostris artis eiusdem amantibus praesident, immo ut disputando probet, antequam aliam mater diplomatis suis commendatō emittat in Britanniam aegrotantem. Londiniensis est; sed constat inter medicos, ut audio, saepe reddi et sanitatem transfuso sanguinis suis derivari passus est. Bis iam Facultas (ut nunc dicitur) Medicinae; sic reformatur Universitas. Speramus ergo, velut transfuso sanguine, sanari posse haec tanta vulnera, ipsique reddi salutem Medicinae. Illud enim sibi proponit ut Aesculapium colat promovendo scientiam.

The degree of M.A. was conferred, by special Graces, on Prof. Ryle and on Dr. G. P. McCullagh, university demonstrator in pathology. The following degrees were also conferred:—

M.D.—G. L. F. Rowell, R. S. Stacey, E. Fretson Skinner, and J. M. Wallace.

M.B. and B.Chir.—T. B. Jones.

M.B.—S. J. Hadfield, R. I. N. Greaves, and R. H. Brown.

Royal College of Physicians of London

At a quarterly meeting of the college held on Oct. 31st, with Lord Dawson of Penn, the president, in the chair, Dr. A. Ramsbottom, Dr. A. Foiling, Prof. O. L. V. S. de Wesselow, Prof. E. H. Kettle, Dr. R. H. Miller, and Dr. P. H. Manson-Bahr were elected councillors, and Dr. H. L. Tidy a representative on the committee of management of the Conjoint Board. The following representatives were elected: Dr. A. S. Barnes on the court of governors of the University of Birmingham; Dr. John Hay on the court of governors of the University of Liverpool; Sir Stanley Woodwork on the Central Council for District Nursing; and Dr. Arthur MacNalty on the executive committee of the Imperial Cancer Research Fund. Mr. Gavin Turnbull Simonds, K.C., was appointed senior standing counsel to the College.

The president announced the award of the Jenks scholarship to John Douglas James, late of Epsom College, and the appointment by the council of Dr. D'Arcy Hart to the Milroy lectureship for 1937. Dr. R. D. Gillespie was appointed a delegate to the fourth biennial conference on mental health in January, 1936.

The following candidates having satisfied the censors board were admitted to the membership:—

Franklin Blecknell, M.B. Oxon.; Thomas Colver, M.B. Sheff.; John Howard Fisher, M.B. Sydney.; Arthur Evans Francis, M.D. Lond.; George Edward Goidber, M.B. Oxon.; John Stuart Harper, M.B. Aberd.; William Albert Hawk, M.D. Toronto.; Thomas Shirley Hele, M.D. Camb.; John Locke Lovibond, M.B. Camb.; William McCartan, M.D. Belg.; James Robertson Monro Mackie, M.D. Aberd.; Robert Walsh Mussen, M.D. Belg.; Lionel Everard Napier, I.R.C.P.; Neville Christopher Oswald, M.B. Camb.; Mahankali Seetharama Rao, M.D. Madras.; Kenneth Moorhouse Robertson, M.D. Lond.; William Stuart Tezner, M.B. Oxon.; Samuel Edward Turvey, M.D. Manitoba.; John Henry Walters, I.R.C.P.; and Sydney Lawrence Wright, M.D. Lond.

Licences to practise were conferred upon 140 candidates (123 men and 17 women) who have passed the final examination of the Conjoint Board and have complied with the College by-laws. The following are the names and medical schools of the successful candidates:—

M. M. Ali, Omania and St. Bart.'s; I. C. Allen, Camb. and St. Thos.; W. G. R. Ashley-Emile, Middlesex; E. Aslan, Guy's; G. Bair, King's Coll.; Margaret Ball, Camb. and Royal Free; A. B. Barbour, St. Bart.'s; K. E. Barlow, Middlesex; J. E. B. Barnes, St. Mary's; H. H. F. Barnes, Univ. Coll.; P. B. Barnah, Calcutta and West Lond.; W. M. Beattie, Camb. and Liverp.; H. B. Birnbaum, Glasg.; L. J. Blay, Guy's; G. L. Broderick, Camb. and St. Thos.; J. A. B. Burnett, Charing Cross; W. A. Burnett, Camb. and Middlesex; A. Z. Butt, Witwatersrand and St. Bart.'s; T. D. Chabiani, Bombay and St. George's; Freda M. Chalkley, King's Coll. and West Lond.; S. L. S. Chiew, Singapore; Priecilla B. Clark and

E. R. Coleman, Univ. Coll.; J. D. Cooper, Camb. and Lond.; R. N. B. Criddle, Oxon. and St. Mary's; H. W. F. Croft, Liverp.; N. Cruickshank, Camb. and Lond.; M. K. Curlois, Guy's; B. Datta, Calcutta and Lond.; D. R. Davies, Cardiff; H. L. Ellis, Middlesex; G. A. Ewen, Camb. and St. Bart.'s; R. D. Ewing, Camb. and Middlesex; J. V. L. Farquhar, Camb. and St. Bart.'s; W. Fielding, Manch.; G. M. Fleming, Camb. and Univ. Coll.; Dalreen I. Forster, Royal Free; T. D. Fraser, Camb. and St. Thos.; E. D. B. Freedman, Univ. Coll. and Westminster; J. French, St. Bart.'s; S. E. Furber, Oxon. and St. Bart.'s; T. H. T. Gaultby, Camb. and Middlesex; P. R. Gavin, St. Thos.; S. G. Gordon, Charing Cross; D. W. F. Goffa, Lond.; A. A. Hakeem, Manch. and West Lond.; P. B. Hanbury, Guy's; C. W. M. Harvey, St. Thos.; B. B. Hickey, Oxon. and Lond.; G. S. Hodge, Univ. Coll.; G. A. Hodgson, Oxon. and St. Thos.; R. J. House, Middlesex; W. Hughes and T. G. Humby, Guy's; R. S. Hunt, Camb. and St. Bart.'s; C. A. Hutt, St. Mary's; R. A. Johnson, Guy's; D. Joy, Univ. Coll.; E. W. Knowles, Liverp.; J. W. Lacey, Camb. and Lond.; C. Langmaid, Cardiff; B. Lee, Manch.; D. N. Leeming, Guy's; J. I. Lesh, St. Thos.; W. N. Lippitt, Birm. and Lond.; H. S. Lohgarh, Punjab and Middlesex; R. G. M. Longridge, Camb. and St. Thos.; I. B. McCrue, Witwatersrand and Charing Cross; K. G. P. Mackenzie, Camb. and St. Thos.; Ivy M. Massick, Punjab and West Lond.; Dorothy V. Mazel, Sydney and Royal Free; S. C. Mehta, Ahmedabad and Lond.; H. C. de B. Milne, Camb. and Westminster; D. W. Moynagh, St. Bart.'s; A. Mukerji, Calcutta and Middlesex; R. Mundy, St. Bart.'s; A. H. G. Munro, Durh.; E. G. Murphy, Univ. Coll.; Maira Murray, Liverp.; A. A. K. Naqshbandi, Punjab and Lond.; S. G. Nardell, St. George's; J. A. V. Nicoll, St. Bart.'s; A. R. H. Oakley, Middlesex; T. D. W. O'Flynn, St. Mary's; C. W. F. Outred, Guy's; S. Paletz, St. George's; G. W. Palmer, Camb. and St. Thos.; Nora M. Pettitt, Royal Free; G. B. S. Plumlett, Westminster; Dorothy S. Pope, Royal Free; D. A. R. Pritchard, Liverp.; C. N. Pulvertaft, Camb. and St. Thos.; J. D. Raftery, St. Mary's; C. O. Ribello, Univ. Coll.; D. T. Richards, Cardiff; Florence G. Richards, Birm.; M. S. Richmond, Leeds; C. G. Rob, Camb. and St. Thos.; E. T. Roberts, Edin. and Leeds; J. M. Robins, Camb. and St. Bart.'s; G. S. Robinson, Camb. and Liverp.; H. D. H. Robinson, Univ. Coll.; P. A. Robinson, Camb. and Middlesex; G. Rogers, Lond.; O. N. Roussel, Camb. and St. Thos.; E. B. Rowe, Guy's; Millicent Rowland, Punjab and Royal Free; L. M. Rubelin, Lond.; A. E. K. Salvi, Guy's; H. N. Savage, Manch.; S. K. Sen, Patna and Birm.; J. A. Seymour-Jones, Camb. and St. Thos.; D. Singh, Lahore and Birm.; Marjorie Small, Adelaide and Royal Free; T. Smallhorn, St. Bart.'s; A. C. Spence, Camb. and Middlesex; S. Stein, Cape and St. Mary's; J. Stern, Lond.; L. D. Stone, Manch.; J. Suchet, Cape and St. Mary's; R. H. A. Swain, St. Bart.'s; J. R. Sweeting and Phyllis J. M. Sykes, Univ. Coll.; R. A. Thatcher, St. Mary's; F. B. Thomas, Camb. and St. Thos.; B. Thornley, Manch.; R. F. Tredgold, Camb. and Univ. Coll.; A. R. M. Wafar, Ceylon and King's Coll.; J. T. Walde, Guy's; Rosemary C. Walker, Royal Free; J. St. J. F. W. Wallace-Collett, Lond.; J. R. Wardley, Manch.; Norah E. Weatherhead, Royal Free; W. R. Welby, Lond.; D. O. Wharton, Camb. and Manch.; C. E. G. Wickham, St. Thos.; Sheila M. R. Williams, Royal Free; S. L. Williams, Cardiff; J. D. Wilson, St. Bart.'s; and Hilda C. Woods, Royal Free and West Lond.

Diplomas were conferred jointly with the Royal College of Surgeons as follows:—

Diploma in Public Health.—K. F. Alford, G. Busuttil, P. J. L. Capon, A. F. Cook, E. H. Hall, P. N. Kapur, A. A. Miller, C. D. Newman, and Constance L. Taylor.

Diploma in Child Health.—R. H. Bailey, D. S. Bateman, C. A. Brehl, A. M. R. Cunn, G. Davison, M. E. Diwany, J. H. Ebbs, L. A. Hawkins, B. McArdle, T. S. Rodgers, and A. B. Stokes.

University of Glasgow

On Nov. 2nd the degree of M.D. was conferred on W. S. Burnet.

University of St. Andrews

Mr. R. C. Alexander has been appointed to the chair of surgery in University College, Dundee, in succession to the late Prof. John Anderson.

Mr. Alexander was born in Edinburgh in 1884 and educated at George Watson's College. He studied medicine at the University of Edinburgh and in Paris, graduating M.B. Edin. with honours in 1908. He obtained a Vans Dunlop scholarship, and until the war he worked in Edinburgh, holding resident appointments at the Royal Infirmary and elsewhere. In 1911 he took the fellowship of the Royal College of Surgeons of Edinburgh, and in 1913 he was a joint holder of the Crichton research scholarship. During the war Mr. Alexander was surgical specialist attached to No. 3 Casualty Station of the Third Army in France. He held the rank of major in the R.A.M.C. and was twice mentioned in dispatches. After the war he returned to Edinburgh as assistant in the surgical department of the University until 1921, when he moved to Dundee. He was appointed hon. visiting surgeon to the Royal Infirmary there and lecturer in clinical surgery in the University of St. Andrews. In 1927 he was appointed examiner in operative surgery and surgical pathology to the Royal College of Surgeons of Edinburgh.

Hunterian Society

A meeting of this society will be held at the Cutlers' Hall, Warwick-lane, London, E.C., on Monday, Nov. 18th, at 9 P.M., when a discussion will be held on the motion that birth control is unnecessary in modern life. The opening speakers will be the Bishop of St. Albans, Dr. C. P. Blacker, Dr. Halliday Sutherland, and Dr. E. R. T. Clarkson.

British Institute of Philosophy

An address entitled *The Present Need of a Philosophy* will be given by Mr. C. E. M. Joad on Tuesday, Nov. 12th, at 8.15 P.M. at University College, Gower-street, London, W.C. Cards of application can be obtained from the director of studies at University Hall, 14, Gordon-square, W.C.1.

Aberdeen University Club, London

The ninety-fourth half-yearly dinner of this club will be held at the Café Royal at 7 for 7.30 P.M. on Thursday, Nov. 21st. Mr. J. M. Bulloch, LL.D., will preside, and General Sir Ian Hamilton will be the principal guest. The hon. secretary may be addressed at 16, Tregunter-road, S.W.10.

Medical Tour to the Mediterranean

The twelfth international medical tour, organised by the Société Médicale du Littoral Méditerranéen, will take place from Dec. 26th to Jan. 4th, and visits will be made to all the resorts of the French Riviera, from St. Raphaël to Mentone, as well as to the hinterland. Further particulars can be obtained from the French National Touring Office, 56, Haymarket, London, S.W.1.

Surgical Instrument Manufacturers' Association

The annual dinner of this association was held at the Holborn Restaurant on Oct. 25th, when Mr. H. Guy Drew (Down Bros.) presided. Prof. Grey Turner, who proposed "The Association," recalled his early delight in instruments of precision. The pride of the industry in its craftsmanship was something which should always be cherished. It added greatly to the interest of their work and could be passed on with the greatest possible advantage to their clients. He was indebted to instrument makers for the way they allowed surgeons to visit their workshops and see how the instruments were made. It would be beneficial, he thought, if a return visit was made to the surgeons' workshops, the operating theatres, to see what was actually done with the instruments. The association might also with advantage form some sort of museum where the vast stocks of patterns of surgical instruments could be housed and to which those who were thinking of inventing instruments could have access. It might often be found that the instruments they had in mind had already been produced and perfected years before! Mr. Drew, who responded, said that skilfully designed surgical instruments had the happy knack of turning up again and again; it was essential for them to be known by the name of the most recent inventor when they embodied improvements on the original design. Heister, who was born in Frankfurt about 1683, wrote a book on surgery which ran into seven German editions and was adopted for many years as the standard book on surgery in the British army; some of his instruments were still being produced, but were not catalogued under his name. Prof. Turner, he said, was voicing their own ideas in saying that the technician of the future must be much more highly trained than he had been in the past. They had recently formed an institute where it was intended to train the young people who were joining the industry in the basic fields of knowledge where surgeon and instrument maker came into contact. Dr. A. N. Gardner proposed "The Guests," and in responding Sir Frederick Hobday expressed his indebtedness to the industry for collaboration in alleviating the sufferings of animals. Dr. Charles Hill, who also responded, urged the institute to seek admission to the register of auxiliaries compiled by the British Medical Association. Mr. Richard Say, on behalf of the Hospital Saving Association, expressed his appreciation of the good work which the instrument makers were doing in endeavouring to raise the quality of surgical appliances and in protecting the public from the quack advertiser.

The King has given permission to Dr. William Dunlop, lately chief medical officer in the Iraq health service, and Mr. G. S. Woodman, lately chief surgical specialist in the service, to wear the order of Al Rafidain, insignia of the fourth class (civil division), which has been conferred on them by the King of Iraq in recognition of their valuable services to his country.

Manchester Babies' Hospital

The Duchess of York has given permission for this hospital to change its name to the Duchess of York Hospital for Babies in Manchester. The hospital celebrated its twenty-first anniversary this year, and Her Royal Highness visited it last July when she opened the new nurses' home and medical block.

Hull Royal Infirmary

The board of management of this hospital have decided to proceed with a scheme for a new block at Sutton for paying patients. There will be an appeal for funds, but the contributions will be regarded as loans carrying interest. Under its charter the infirmary cannot itself carry this out, and the appeal will probably have to be undertaken by an independent body.

University of Birmingham

A special post-graduate course in neurology for candidates preparing for the diploma in psychological medicine of the conjoint board will be held from May 5th to July 14th on Tuesday afternoons at the General Hospital, the Queen's Hospital, and the Cripples Hospital. The lecturers will be Mr. Beatson Hird (neurological ophthalmology), Prof. P. C. Cloake (neurology), Dr. Keith Thompson (neuro-pathology), Mr. G. P. Mills (neurological orthopaedics), and Dr. J. F. Brailsford (radiology of the nervous system). Further particulars may be had from the secretary of the University.

Cleaner Swimming Pools

The Minister of Health has been drawing the attention of local authorities to the necessity for cleanliness in swimming-pools. The official circular (No. 1503) points out that the coming of winter provides an opportunity for ensuring that suitable standards of cleanliness and purity of water are maintained. The report on the Purification of the water of Swimming Baths, published by the Ministry in 1929, is quoted as recommending continuous filtration combined with continuous and accurately controlled chlorination (or other equally effective means of sterilisation). Besides baths and pools in public ownership there are those provided by private owners (e.g., in connexion with road-houses and similar premises), and the circular indicates the statutory powers of control which local authorities can exercise, if need be, over such pools used by the public.

The Irish Free State Medical Union

Our Irish correspondent writes: At the representative meeting of the British Medical Association last July sanction was given to a proposal for the union of the branches of the B.M.A. in the Free State with the Irish Medical Association. The latter body, which had previously given approval of the project, has now passed the necessary legal resolutions for winding-up. Two special general meetings were held on Oct. 16th and 31st, and decisions taken in legal form. It is expected that the new union—the title of which will be "the Irish Free State Medical Union (Irish Medical Association and British Medical Association)"—will come into being on Jan. 1st, 1936. All the members of both associations who are resident in the area under the jurisdiction of the Irish Free State will automatically become the first members. The Union will have complete autonomy within the Irish Free State, but arrangements have been made by which the members will receive the *British Medical Journal*, and the Union will be represented on the council of the Association. Moreover, a member leaving the Irish Free State to reside in Great Britain or in any other area where there is a branch of the B.M.A. will automatically become a member of that association. Conversely, members of the B.M.A. coming from Great Britain or elsewhere will become members of the Union. The first election of officers and committees will take place next summer, the management of the Union in the meantime being by a provisional committee.

OBITUARY

WILLIAM ADAMS FROST, F.R.C.S. Eng.

CONSULTING OPHTHALMIC SURGEON TO ST. GEORGE'S HOSPITAL.

The death of Mr. Adams Frost at 82 years of age marks a breach with the past. Forty years ago he was the best known of British ophthalmologists; he was an original member of the Ophthalmological Society of the United Kingdom and the last survivor in this country of that little group. For many years he had been living in retirement.

William Adams Frost was educated at Kensington Grammar School. His father, Charles Maynard Frost, F.R.C.S., was a London Hospital man, but he was surgeon to the Kensington Dispensary and lived in Ladbroke-square, from which it was a pleasant walk across the park to St. George's, where the son studied medicine and from which he qualified in 1874, becoming house surgeon and demonstrator of anatomy. After post-graduate study in Vienna he took his F.R.C.S. in 1878, and three years later was appointed assistant ophthalmic surgeon to the hospital. In 1892 he succeeded Mr. Brudenell Carter as full surgeon, and remained on the active staff until his retirement in 1906. For much of this time he was also surgeon to the Royal Westminster Ophthalmic Hospital, and ophthalmic surgeon to the Victoria Hospital for Children. At St. George's he lectured on ophthalmic surgery, and he was tireless in giving elementary instruction to students who had no intention of becoming specialists; at the Westminster he made good use of a collection of lantern slides (taken from his atlas) to ground more advanced pupils in the recognition of the normal and abnormal fundus picture. He did not write much but his "Atlas of the Fundus Oculi," which appeared in 1896, was an important contribution to ophthalmic literature; some attempts had previously been made in this direction, but Frost's early training at Moorfields and his later attachment to large ophthalmic hospitals gave him the opportunity of capturing topical and interesting cases at the right moment, and of supervising the artist in order that the essential points might be effectively brought out. The atlas contained all the important forms of disease which the student or practitioner was likely to meet with, and Mr. Frost was happy in his artist, Mr. A. W. Head, whose drawings bore the impress of fidelity. His other publication was a little manual of ophthalmic surgery in which he collaborated with Brudenell Carter, who took the anatomy and physiology, while Frost discussed the diseases of the eye and its setting. The chief value of this book lay in the sections on the refraction of the eye and the correction of errors of refraction which Mr. Frost was one of the first to make clear to the student. He devised a useful artificial eye for the purpose of teaching the use of the ophthalmoscope to students, and his model of ophthalmoscope was in some ways superior to Morton's. The operation of putting a glass globe into Tenon's capsule, after excision of the eye, still bears his name. At the Ophthalmological Society he was twice awarded the *Middlemore* prize; he was for many years librarian of the Bowman library and vice-president of the society.

Mr. Harold Grimsdale writes: "It was my privilege to be associated with Mr. Frost, as clinical assistant and later as assistant surgeon for many years both at St. George's and at the Royal Westminster. It is not easy to express the great regard I had for him; he was an ideal colleague, always ready to

help and to listen to one's difficulties. He criticised but never unkindly. His most marked characteristic was keenness; whatever he took up he enjoyed to the full. Apart from his work, which he loved, he played hard. As a young man he was an enthusiastic cyclist; when motors came in he became an equally enthusiastic motorist. He hunted, played golf and bridge, always putting his whole heart into the matter in hand. In his last years his sight failed, and he who had done so much to help the sight of others himself slowly became blind; but even this tragedy he met courageously. He came constantly to the committee meetings of the Westminster, and by his wise advice and interest did much to make the hospital flourish."

In January, 1881, Mr. Frost married Miss M. D. Anderson, who survives him. There were no children of the marriage.

**WILLIAM ARTHUR WINTER, M.D. Dub.,
F.R.C.P. Irel.**

Dr. Winter's death in Dublin last Saturday was unexpected to his friends, few of whom knew that he was not in sound health. He was a Dublin man by birth, being born in the city in 1868, and was educated at Trinity College, Dublin. After graduating in 1891 he was for a few years engaged in general practice in the north of England, after which he returned to Dublin to practise as a physician. He was for some years assistant physician to Dr. Steevens' Hospital, and in 1906 was elected visiting physician to that hospital, a post he held up to his death. He filled various offices in the Royal College of Physicians, and was its president from 1927 to 1930. During the late war he served for a time with the "83 (Dublin) General Hospital" in France, holding the rank of major in the Royal Army Medical Corps.

A careful and conscientious hospital physician, Winter for many years enjoyed a large private practice chiefly of the family type; it was a tribute both to his skill and to his kindness that he retained his earlier patients through life, and very often their children and grandchildren became his patients also. He was so unassuming that his capacity and dignity as president of the College exceeded the anticipations even of his friends. Only a few weeks ago he proposed the toast of the guests at the St. Luke's Day dinner with neatness, good feeling, and tact. A very "clubbable" man and a bachelor he was held in general affection, his courtesy and willingness to do a favour being patent to all.

SIR THEMISTOKLES ZAMMIT, C.M.G., M.D.

THE death in Malta on Nov. 3rd of Sir Themistokles Zammit, at the age of 72, removes from his native island a wise counsellor who, holding himself aloof from purely party politics, has left a deep impress upon its sociological and academic life; from the world of scientific investigation an outstanding personality; and from a smaller circle, to which he was familiarly known as Tem or Temmy, a loyal and beloved friend.

Born in 1864, Zammit was educated at the Malta University where he pursued the study of medicine, and in due course graduated M.D. in 1889. Attracted by the possibility of devoting himself to analytical chemistry, he applied for, and was appointed in 1891 to, the post of government analyst, which he

held for 30 years. He took up his work in the laboratories of the Public Health Department under the then chief medical officer, Caruana Scicluna, who had himself helped Bruce in his preliminary investigations into the aetiology of Mediterranean fever. At this moment, Captain Hughes, who followed Bruce in the serious study of this disease, stepped into the laboratory, and in his turn received much assistance in his researches from Zammit. From the earliest stages of his government service, Zammit was thus in close touch with the development of our knowledge of undulant fever, a fact which made him a tower of strength to the Mediterranean Fever Commission from 1904 to 1907. The discovery of the elimination of the specific micro-organism of the disease via the milk of the goat was due to him—and

the study of means for the prevention of brucella infections afforded him intermittent occupation throughout his life. His numerous publications on the subject are scattered through English, French, and Italian journals; and a note from his pen on the immunisation of the Maltese goat appeared in our own columns only two years ago. Previously to the advent of the Mediterranean Fever Commission

SIR THEMISTOKLES ZAMMIT

he had already made his mark in the investigation of an outbreak of malaria in Malta, which he successfully dealt with by tracing the anopheles to its only habitat in the island—a small but deep valley—and there destroying it.

For a period of 25 years Zammit played a very active part in university life. In 1905 he was appointed to the chair of chemistry—a post which he retained until 1920—when he exchanged it for the rectorship of the university, becoming at the same time a member of the Legislative and of the Executive Councils of Malta. These posts he held until 1926, when on retiring from the rectorship he was appointed director of the museum department, and was enabled to give free rein to his antiquarian pursuits. Honours naturally fell to his share. In 1911 he became C.M.G.; in 1919 he received the hon. fellowship of the Royal Anthropological Institute; in 1920 the University of Oxford conferred upon him the degree of D.Litt. (hon. causa); in the same year he was awarded the Mary Kingsley medal of the Liverpool School of Tropical Medicine; and ten years later he was created a knight.

Zammit was indeed a versatile and many-sided person, and whatever study he turned to has been enriched by his work. He was a patient, exact, and logical scientific worker, an erudite archaeologist, and an academic dignitary whose sound judgment and logical mind steered the university through many troublous times.

He leaves one son—assistant curator of the museum—and one daughter.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, Nov. 12th.

Therapeutics and Pharmacology. 5 P.M. Prof. E. C. Dodds: The Pharmacological Action and Clinical Use of Drugs with a Camphor- and Coramine-like Action.

Psychiatry. 8.30 P.M. Dr. John Brander: The Study of the Human Pituitary in Health and Disease.

WEDNESDAY.
Surgery: Sub-section of Proctology. 5 P.M. Mr. G. Gordon-Taylor: The Complex and Complicated in the Surgery of the Large Intestine (presidential address).

FRIDAY.

Radiology. 8 P.M. for 8.15 P.M. (British Industries House, Marble Arch, W.). Dr. Allibone: Continuously Evacuated X Ray Tubes. Other speakers: Dr. Ralston Paterson, Dr. F. Ellis, and Dr. N. S. Finzi.

Epidemiology and Tropical Diseases. 8.15 P.M. Sir W. Dalrymple-Champneys, Dr. R. Briercliffe, Dr. T. B. Wigglesworth, and Dr. P. H. Manson-Bahr: The Malaria Epidemic in Ceylon, 1934-35 (joint discussion).

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.
MONDAY, Nov. 11th.—8 P.M., Clinical Evening.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY.

THURSDAY, Nov. 14th.—8.30 P.M. (at 11, Chandos-street, W.), Dr. J. A. Hadfield: A Contribution to Psychopathology.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY, Royal Northern Hospital, N.W.

FRIDAY Nov. 15th.—9 P.M., Clinical Evening.

SOUTH-WEST LONDON MEDICAL SOCIETY.

WEDNESDAY, Nov. 13th.—9 P.M. (Bolingbroke Hospital, Bolingbroke-grove, S.W.), Mr. E. T. C. Milligan: Modern Methods and Treatment of Ano-rectal Diseases.

PADDINGTON MEDICAL SOCIETY.

TUESDAY, Nov. 12th.—9 P.M. (Great Western Royal Hotel, W.), Miss M. J. Roxburgh, Miss E. Wetherall, and Miss D. Anderson: Hospital Almoners and the Medical Practitioner.

BIOCHEMICAL SOCIETY.

FRIDAY, Nov. 15th.—4.30 P.M. (Guy's Hospital medical school, S.E.), Short Communications.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION, 11, Chandos-street, W.

FRIDAY, Nov. 15th.—5 P.M. Mr. E. Wilson Hall: Some Problems of the Medical Officer in Private Preparatory Schools.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

TUESDAY, Nov. 12th.—5 P.M., Dr. J. D. Rolleston: The History of the Acute Exanthemata (last FitzPatrick lecture).

THURSDAY.—5 P.M., Dr. C. G. Seligman, F.R.S.: The Roman Orient and the Far East (Lloyd-Roberts lecture).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.1.

MONDAY, Nov. 11th to SATURDAY, Nov. 16th. Wed., 8.30 P.M. (1, Wimpole-street, W.), Dame Janet Campbell, Prof. J. M. Munro Kerr, Prof. G. I. Strachan, and Prof. Daniel Douglass: That the present rate of maternal mortality is a discredit for modern obstetrics (open to all members of the medical profession).—

INFANTS' HOSPITAL, Vincent-square, S.W. Mon., Wed., and Fri., 8 P.M., Course for the F.R.C.S. (Primary) in anatomy and physiology.—ST. PETER'S HOSPITAL, Henrietta-street, W.C. All-day course in urology.—

ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. All-day course in medicine, surgery, and gynaecology.—Courses and lectures open only to members of the Fellowship.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Nov. 11th.—3.30 P.M., Dr. Symonds: Intracranial Pressure.

TUESDAY.—3.30 P.M., Dr. Critchley: Epilepsy and Allied Conditions.

WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.

THURSDAY.—3.30 P.M., Dr. Walshe: The Motor System (I.).

FRIDAY.—3.30 P.M., Dr. Bernard Hart: The Psychoneuroses (VI.).

Out-patient clinic daily at 2 P.M.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Nov. 14th.—2 P.M., Mr. A. Simpson Smith: Clinical Cases. 3 P.M., Dr. W. W. Payne: Diabetes (Part III.), Complications and their Treatment.

Out-patient Clinics daily at 10 A.M. and ward visits (except on Wednesdays) at 2 P.M.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE EAR, NOSE, THROAT, AND CHEST, Hardman-street, Deansgate, Manchester.

WEDNESDAY, Nov. 13th.—4.30 P.M., Dr. Vernon Smith: Nasal Polypi.

ST. PAUL'S HOSPITAL, Endeell-street, W.C.

WEDNESDAY, Nov. 13th.—4.30 P.M., Mr. Stanford Cade: Radiation in Cancer of the Urinary Tract.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, N.W.

WEDNESDAY, Nov. 13th.—4 P.M., Mr. H. Lawson Whale: Fads and Fancies in Laryngology.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, Nov. 11th.—10 A.M., Medical wards and skin clinic. 11 A.M., Surgical wards. 2 P.M., Surgical and gynaecological wards, eye, and gynaecological clinics. 4.15 P.M., Mr. Green-Armytage: Trial Labour versus Induction.

TUESDAY.—10 A.M., Medical wards. 11 A.M., Surgical wards. 2 P.M., Throat clinic. 4.15 P.M., Dr. Owen: Hemorrhage and Jaundice.

WEDNESDAY, 10 A.M.—Children's ward and clinic. 11 A.M., Medical wards. 2 P.M., Eye clinic. 4.15 P.M., Demonstration of eye cases.

THURSDAY.—10 A.M., Neurological and gynaecological clinics. Noon, Fracture clinic. 2 P.M., Eye and genito-urinary clinics.

FRIDAY.—10 A.M., Skin clinic. 2 P.M., Throat clinic. 4.15 P.M., Mr. Vlasto: Pain in the Ear.

SATURDAY.—10 A.M., Medical wards, children's and surgical clinics.

The lectures at 4.15 P.M. are open to all medical practitioners without fee. Operations, medical and surgical clinics daily at 2 P.M.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.

WEDNESDAY, Nov. 13th.—4 P.M. (St. James' Hospital, Ouseley-road, S.W.), Dr. G. Braun: Dr. Lettermann's Foot Corrective System, a biological method.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.

THURSDAY, Nov. 14th.—9 P.M., Mr. St. J. D. Buxton: Tubercle of Bones and Joints.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.

TUESDAY, Nov. 12th.—5.30 P.M., Dr. M. T. Morgan: Health Inspection of Meat and Meat Products destined for export in the great abattoirs of South America (Benjamin Ward Richardson lecture).

ST. JOHN CLINIC, Ranelagh-road, S.W.

FRIDAY, Nov. 15th.—4.30 P.M., Dr. Albert Eidinow: Principles of Local and General Light Therapy.

INSTITUTE OF HYGIENE, 28, Portland-place, W.

WEDNESDAY, Nov. 13th.—3.30 P.M., Mr. William Ibbotson: Hygiene of Breathing, Hearing, and Speaking.

LONDON SCHOOL OF DERMATOLOGY, 49, Leicester-square, W.C.

TUESDAY, Nov. 12th.—5 P.M., Dr. H. MacCormac: Malignant Growths of the Skin.

WEDNESDAY.—5 P.M., Dr. I. Muende: Histopathology of Chronic Granulomatata.

THURSDAY.—5 P.M., Dr. Hugh Gordon: Cutaneous Affections due to Sunlight.

UNIVERSITY OF SHEFFIELD.

FRIDAY, Nov. 15th.—3 P.M. (Royal Hospital), Dr. C. Gray Imrie: Medical Cases. 3 P.M. (Royal Infirmary), Dr. A. Gurney Yates: Medical Cases. 3 P.M. (Jessop Hospital), Prof. John Chisholm: Gynaecological Cases.

SUNDAY.—10.30 A.M. (Royal Hospital), Dr. C. Gray Imrie: Medical Cases. 10.30 A.M. (Royal Infirmary), Dr. A. Gurney Yates: Medical Cases. Mr. R. St. L. Brockman: Surgical Cases. 10.30 A.M. (Jessop Hospital), Mr. Eric Stacey: Gynaecological Cases.

GENERAL INFIRMARY, Leeds.

TUESDAY, Nov. 12th.—3.30 P.M., Mr. Foster: Epiphora: cases illustrating causation and treatment.

PUBLIC DISPENSARY AND HOSPITAL, Leeds.

WEDNESDAY, Nov. 13th.—4 P.M., Dr. H. H. Moll: Emphysema.

ROYAL INFIRMARY, Manchester.

TUESDAY, Nov. 12th.—4.15 P.M., Mr. D. M. Sutherland: Abdominal Injuries.

FRIDAY.—4.15 P.M., Dr. T. H. Oliver: Demonstration of Medical Cases.

ST. MARY'S HOSPITALS, Manchester.

THURSDAY, Nov. 14th.—4.15 P.M. (Whitworth-street West Hospital), Mr. Arnold Jones: The Present Position of the Operation for the Removal of Tonsils and Adenoids.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, Nov. 13th.—4.15 P.M. (Royal Infirmary), Prof. J. A. G. Burton: The Acute Abdomen.

Buxton Clinic for Rheumatism and Allied Diseases.—H.P. At rate of £150.

Cambridge, Addenbrooke's Hospital.—H.P. At rate of £130.

Cancer Hospital, Fulham-road, S.W.—Res. M.O. £200. Med. Reg. £150. Also H.S. At rate of £100.

Carshalton, Surrey, Queen Mary's Hospital for Children.—H.P.

At rate of £120.

Chelsea Hospital for Women, Arthur-street, S.W.—Jun. H.S.

At rate of £100.

Chester City and County of.—Deputy M.O.H., &c. £500.

City of London Hospital for Diseases of the Heart and Lungs,

Victoria Park, E.—Walton Marsh Barnes Research Scholarship, &c. £500.

Constance-road Institution, East Dulwich, S.E.—Asst. M.O. £230.

Croydon General Hospital.—Res. M.O. £200.

Dreadnought Hospital, Greenwich, S.E.—Receiving Room

Officer. At rate of £200.

Edinburgh, National Committee for the Training of Teachers.—

M.O. and Lecturer on Hygiene for Aberdeen Training

Centre. £725.

Egyptian Government.—Principal M.O.H. of Cairo. L.E. \$40-

984. Also Director, Serum and Vaccine Institute, Cairo.

L.E. \$40-984.

Fulham Hospital, St. Dunstan's-road, W.—Asst. M.O. £250.

Golden-square Throat, Nose, and Ear Hospital, W.—H.S. £100.

Guildford, Royal Surrey County Hospital.—H.S. £150.

Hospital for Sick Children, Great Ormond-street, W.C.—Res.

M.O. for Country Branch. At rate of £250. Also Res.

Anæsthetic Registrar. At rate of £150.

Hospital for Women, Soho-square, W.—Surgeon in Charge of

Out-patients.

Hull Royal Infirmary.—Cas. O. At rate of £150.

Jersey General Hospital and Poor Law Infirmary.—Radiologist.

£500.

Leicester, City General Hospital.—Deputy Med. Supt. £500.

Leeds City.—Asst. Clin. Tuberc. O. £550.

Leeds, Menston Mental Hospital.—Fifth Asst. M.O. £350.

Liverpool Hospital for Consumption and Diseases of Chest,

Mount Pleasant.—Hon. Asst. Physician.

Manchester, Ancoats Hospital.—H.S. to Ear, Nose, and Throat

Dept. At rate of £100.

Manchester City.—Asst. Tuberc. O. £650.

Manchester Northern Hospital, Cheetham Hill-road.—Res. M.O.

£150.

Metropolitan.—Hon. Asst. Surgeon.

Miller Ge.—M.O. £250.

Miller Ge.—S.E.—Cas. O. At

rate of £150. Also H.P. and H.S. Each at rate of £100.

Newark General Hospital.—Res. H.S. £175.

New End Hospital, Hampstead, N.W.—Asst. M.O. £250.

Northampton General Hospital.—H.S. At rate of £150.

Norwich, Norfolk and Norwich Hospital.—Cas. O. £120.

Nottingham Children's Hospital.—Res. H.P. At rate of £150.

Nottingham City Hospital.—Res. Surg. O. £350. Also two

H.S.'s. Each at rate of £150.

Preston, Biddulph Grange Orthopaedic Hospital.—Jun. H.S. At

rate of £150.

Princess Elizabeth of York for Children, Shadwell, E.—Res. M.O.

£200.

Romford, Oldchurch Hospital.—Jun. Res. M.O. £250.

Royal College of Physicians, Pall Mall East, S.W.—Leverhulme

Research Scholarship. £500.

Royal Free Hospital and London School of Medicine for Women,

Hunter-street, W.C.—Third Res. Asst. £270. Also Res.

Asst. Path. £150. Also Anæsthetist Registrar. £100.

Royal Northern Hospital, Holloway, N.—Second Ophth. Surgeon.

Royal Waterloo Hospital for Children and Women, Waterloo-

road, S.E.—H.S. At rate of £100.

St. Mary, Islington, Hospital, Highgate Hill, N.—Asst. M.O.

£350.

St. Pancras Hospital, Pancras-road, N.W.—Asst. M.O. £250.

Salisbury General Infirmary.—Res. M.O. £250.

Salvation Army, Mothers' Hospital, Lower Clapton-road, E.—

Sen. Res. M.O. £150. Also Jun. Res. M.O. At rate

of £80.

Sheffield, Jessop Hospital for Women.—H.S. At rate of £100.

Southampton, Royal South Hants and Southampton Hospital.—

H.P. Cas. O. Also H.S. to E.N.T. Dept. and Res. Anæ-

sthetist. Each at rate of £150.

Stafford, Slandon Hall Orthopaedic Hospital.—H.S. £200.

Sunderland Royal Infirmary.—H.S. and H.P. Each at rate

of £120.

Swansea General and Eye Hospital.—Cas. O. At rate of £150-

£175.

Talgarth, Breconshire, South Wales Sanatorium.—Asst. Res.

M.O. £200.

Taunton and Somerset Hospital.—H.P. and H.S. Each at

rate of £100.

Tunbridge Wells, Kent and Sussex Hospital.—Res. Surg. O.

£250.

Walsall, Manor Hospital.—Asst. M.O. £350.

West End Hospital for Nervous Diseases, 73, Welbeck-street, W.—

Registrar. £200. Also two Hon. Med. Psychologists.

West London Hospital, Hammersmith-road, W.—Physician to

X Ray (Therapeutic) and Electrical Depts.

Wimbledon Hospital, Thurstan-road, S.W.—Res. M.O. At rate

of £150.

Winchester, Royal Hampshire County Hospital.—H.S. At rate

of £125.

Wokingham, Berks, Pinecroft Sanatorium.—Asst. M.O. £250.

Wolverhampton, New Cross Hospital.—Asst. Res. M.O. £200.

Woolrich and District War Memorial Hospital, Shooters Hill,

S.E.—Two H.S.'s. Each at rate of £100.

Worcester Royal Infirmary.—Hon. Anæsthetist.

York County Hospital.—H.S. to Eye, Ear, Nose, and Throat

Dept. Also H.P. Each £150.

The Chief Inspector of Factories announces a vacancy for a

Certifying Factory Surgeon at Kel-o (Roxburgh).

Vacancies

For further information refer to the advertisement columns Adelaide, South Australia, University and Hospital.—Director of Bacteriology and Pathology.

Assam, India, Welch Presbyterian Mission Hospital, Shillong.—Surgeon.

Babies' Club, Chelsea.—Additional M.O. £1 11s. 6d.

Barnstaple, North Devon Infirmary.—Res. M.O. At rate of £150.

Bath, Royal United Hospital.—Asst. Hon. M.O. to Physio-

Therapy Dept.

Birmingham, Queen's Hospital.—Res. Surg. O. £150.

Bovey Tracey, Hawkmoor Tuberculosis Sanatorium.—Res. M.O.

£250.

Brentwood, Essex, High Wood Hospital for Children.—Asst. M.O.

£250. Also H.P. At rate of £120.

Brighton, New Sussex Hospital for Women, Windlesham-road.—

Hon. Asst. Ophth. Surg. Also H.P. £100.

NOTES, COMMENTS, AND ABSTRACTS

THE VACCINATION QUESTION

In a Chadwick lecture given in London on Nov. 1st Dr. C. Killick Millard, late medical officer of health for Leicester, sought common ground in which opponents and supporters of vaccination may bury their differences. In the past, he said, one either had to believe in vaccination or disbelieve in it, and the result had been a contest of extremes. While his own faith in vaccination, as a means for protecting the individual against small-pox, was as strong and unassailable as ever, he recognised that, as a State institution, for protecting the community, infant vaccination had been largely a failure. The case of this country in 1871-2, and of India to-day, were outstanding illustrations of this. It was lack of sanitation, not of vaccination, which was the true cause of the appalling small-pox mortality which persisted in India. He believed that the medical profession, from Jenner onward, had claimed too much for vaccination, and that vaccination had been credited with having reduced small-pox mortality in this country much more than it had really done. To-day this was being recognised by the medical profession, or at least by medical officers of health, and it could hardly be otherwise, for in spite of continuous and increasing neglect of infant vaccination small-pox mortality had almost disappeared. Until a few years ago it was taught as a cardinal medical dogma that the neglect of infant vaccination entailed serious and imminent risk of small-pox mortality returning. But the city of Leicester had openly abandoned infant vaccination 50 years ago, and there had only been two deaths from small-pox there in the last 30 years. Dr. Millard took the view that the "ultra-mild" form of small-pox seen in this country of late years is a distinct variety which breeds true. This "variola minor" presents quite a different administrative problem from variola major; it is non-fatal, non-disfiguring, non-loathsome. In some ways it is no more serious than vaccination, and no case, he thinks, can be made out for retaining compulsory vaccination merely on account of it. In Dr. Millard's opinion the repeal of the Vaccination Acts is now overdue.

THE LIMITATIONS OF RADIODIAGNOSIS

THE warning that the radiological method is the servant and not the master of the physician is no new one, but Dr. H. A. Christian¹ has illustrated it aptly with some interesting examples of diagnostic difficulties. Severe and persistent backache, for instance, may suggest to the clinician osteoarthritis of the spine or new growth of the vertebrae. The radiologist may report that there is no evidence of new growth or that there is evidence of osteoarthritis, yet neither report is sufficient justification for abandoning a strong clinical suspicion that new growth is present. Pleural fluid, recurring in the absence of cardiac insufficiency, is a very important sign of new growth in the absence of any local X ray evidence. Prolonged fever again may be the only sign of new growth at some time. Often enough indeed, Dr. Christian points out, the X ray diagnosis lags behind the clinical. In abscess of the lung, for example, there may be fever, foul sputum, and physical signs several days before the X ray is able to reveal the abscess cavity with fluid level, because in the earlier stage the cavity is filled with exudate similar to that in the surrounding lung tissue and no contrast is perceptible. There is a similar lag in osteomyelitis and mastoiditis, and the consequences of waiting for X ray confirmation may be very grave. Tubercle bacilli may be found before a radioscopic lesion is present, just as in other cases the X ray may reveal an unsuspected tuberculosis. The wise

physician needs no warning of this lag, but there may be practitioners who expect too much from and place far too much reliance on the X ray contribution to the problem of diagnosis.

SMOKE AND THE NATIONAL OUTLOOK

SPEAKING on this subject at a conference held recently in Peterborough, Dr. R. Veitch Clark, medical officer of health for Manchester, said that the unnecessary production of smoke in this country has far-reaching disadvantages to the nation, not only the rough serious damage to physical and mental well-being, but in waste of fuel resources, increased cost of maintenance of buildings, and harm to agriculture. Possibly, however, the atmospheric gloom and dirt associated with smoke, by its influence on the mind, was most damaging of all in its reaction on national movements and national life. Experience showed, Dr. Clark said, that only in the larger areas of local government was smoke control even reasonably possible, and the smoke nuisance should therefore be administratively supervised by joint smoke boards, operating as do river boards, and covering an area large enough to make effective standardisation of smoke emission generally practicable. Such a board would be able to maintain a staff capable of meeting and discussing problems of fuel consumption, both with industrialists and with local authorities responsible for housing and the production of domestic smoke. This coöperative effort would do far more good than any penal legal enactments.

BOMBAY 100 YEARS AGO

Sir Edward West, appointed recorder of Bombay by the Crown in 1822, and afterwards chief justice, set about the reform of the law courts. With no support from the Governor, and met by antagonism from the supreme court and the East India Company's advocates, he pursued his single-minded fight for justice, and became so much beloved by the natives that at his death Hindus, Mohammedans, and Parsees all contributed to found a scholarship in his honour. He was the first judge to sit with a jury which included natives. Dr. F. D. Drewitt has collected and edited his memoirs which now appear in a revised edition² including some hitherto unpublished letters from Archdeacon Barnes who accompanied Bishop Heber in Bombay. Dr. Drewitt has a pleasing straightforward style of writing and the addition of passages from Lady West's journal adds to the interest of the book.

A DOCTOR ON SWIMMING

Dr. G. B. Brewster has made eight attempts to swim the Channel. He has described them in a little book³ which also contains some notes on the health value of swimming and on training for long swims. Written with a naïveté which is by turns charming and irritating, the book reveals a tenacity in the face of difficulties and bad luck worthy, perhaps, of a better cause. To those who are familiar only with the more usual methods of crossing to the Continent, the chief surprise will be the very few days in every year—half a dozen or so—in which an attempt can be made to swim the Channel, and it is no wonder that on those days the beach at Dover should be thick with swimmers and that the boats available to accompany them should "fall to the longest purse." One fact revealed by Dr. Brewster may discourage even the patient and wealthy long distance swimmer: he may be just as sea-sick as on a cross-channel steamer.

¹ Bombay in the Days of George IV. Second edition. By F. Dawtrey Drewitt, M.D., F.R.C.P. London: Longmans, Green and Co., Ltd. 1935. Pp. 342. 10s. 6d.

² My Channel Swimming Adventures. By G. B. Brewster, M.B., Ch.B. London: John Bale, Sons and Danielsson Ltd. 1935. Pp. 71. 2s. 6d.

³ New Eng. Jour. Med., Sept. 26th, 1935, p. 593.

SOCIAL SURVEYS

AN inquiry into the aims and scope of British local social surveys, undertaken in order to judge whether or not further surveys should be encouraged, has had as its outcome an informative little book¹ on the local social survey in Great Britain. The author distinguishes between "typical" surveys in which various social conditions (in particular the extent and causes of poverty) are examined in one area as a sample of conditions in the country as a whole, and "regional" and "community" surveys in which stress is laid on the special problems of the area under consideration and an attempt is made to educate local public opinion to tackle these problems. Mr. Wells concludes that the survey has been definitely successful, both in ascertaining facts and in stimulating to activity. He recommends that further survey work should be done particularly in rural areas, and on aspects of social life not already dealt with. It is doubtful whether this book would be very illuminating to a reader unacquainted with any actual survey, but if it sends such a reader to study the surveys themselves that is all to the good. A useful bibliography lists 31 general social surveys, ranging in time from Charles Booth's classical work on London down to the Merseyside and other recent surveys, and also 124 surveys dealing with special topics.

AIR-RAID PRECAUTIONS

SINCE it seems still necessary that the "active" part of the population must spend time and energy in devising schemes for preventing the "passive" part of the population from being blistered, burnt, and asphyxiated from the air, a catechism on gas warfare recently published serves a necessary purpose.² Major Hammer answers in clear and simple language questions on the properties of the various poison gases; on protection and decontamination, both personal and collective; on the first-aid treatment and nursing of gas casualties; and on the organisation necessary in an air raid. Two appendices deal respectively with respirator drill and the administration of oxygen, and some blank pages are added for notes—or perhaps for a Last Will and Testament. Without diagrams and fuller explanations or practical demonstrations the book is not complete in itself, but to refresh or clarify the mind of an intelligent civilian who has been through a course of air-raid precautions and first aid for gas casualties it should prove most useful. To instructors and medical men generally it will serve as a reminder of many points easily forgotten. No criticisms of the matter are called for, but in connexion with face wounds and respirators the sentence "care must be taken that padding or bandages do not cause a bad fit" is open to misinterpretation, as is the horrible phrase a "pussy" discharge."

A USEFUL DIET BOOK

A NOTE from the printers informs us that this diet book³ has been compiled by Dr. H. S. Pemberton, honorary physician to the David Lewis Northern Hospital, Liverpool, and the preface tells us that the diets and tables contained in it have been used for some years in the wards and dietetic clinic of that hospital. The work appears in such a modest form and the diets are printed with such complete absence of explanatory paragraphs that its essential excellence may be overlooked. But close examination of the volume leads to the conclusion that it epitomises all that can usefully be said about diets at the present time.

A diet must be adapted to the country as well as

to the disease and to the individual, and these are essentially practical diets for British people. Dogmatism as to the exact analyses of any diet or even any article of food is always unscientific because items of food must vary considerably in their constitution according to their season and methods of cultivation; with admirable modesty the compilers state that no great accuracy can be claimed for any figure or percentage given in view of the topographical and seasonal variations revealed by analyses of articles of food. We can heartily commend this book to all practitioners who wish to employ dietetics in a practical and scientific manner.

Appointments

EVANS, P. J., M.B. Camb., F.R.C.S. Eng., D.O.M.S., has been appointed Assistant Ophthalmic Surgeon to the Birmingham United Hospital for duty at the Queen's Hospital.

WATSON, ROBERT, M.B. Belf., F.R.C.S. Edin., M.C.O.G., Hon. Obstetric Surgeon to the Northampton General Hospital.

Births, Marriages, and Deaths

BIRTHS

ANDERSON.—On Oct. 25th, at Shrewsbury, the wife of Dr. F. A. Anderson, of a son.

KERR.—On Oct. 31st, the wife of J. A. Kerr, M.D., of Lansdowne Avenue, Grimsby, of a son.

ROTHERHAM.—On Oct. 27th, the wife of Dr. E. B. Rotherham, Grimsby, of a daughter.

MARRIAGES

LOW—GEMMILL.—On Oct. 29th, at Merrylea Parish Church, Glasgow, Edward Bruce Low, M.B., Ch.B. Edin., Shoreham-by-Sea, Sussex, to Clair Gemmill, daughter of Mrs. Jessie Biggar, Newlands, Glasgow.

PORTER—STOWELL.—On Nov. 2nd, at the church of St. Cross, Knutsford, Cheshire, T. W. Herdman Porter, B.M. Oxon., M.R.C.S. Eng., only son of Dr. and Mrs. Hordman Porter, of Faversham, Kent, to Pamela, only daughter of Mr. and Mrs. Herbert Stowell, of Knutsford.

RENSHAW—ROLFE.—On Oct. 30th, at the Twickenham Memorial Chapel, Arnold Renshaw, M.D. Lond., of Manchester, to Barbara Joan, elder daughter of the late Edgar C. Rolfe and Mrs. Rolfe, of Sheringham.

TREVOR—BLYTH.—On Oct. 26th, at St. Stephen's Church, Ipswich, David Trevor, M.S. Lond., F.R.C.S. Eng., of London, to Kathleen Fairfax Blyth, niece of Miss Mary Blyth, of Ipswich.

DEATHS

GARDE.—On Oct. 23rd, at Mombasa, Alfred Jervoise Garde, M.B. Dub., Uganda Medical Service, son of Surg. Capt. and Mrs. Garde, of Falmouth, aged 29.

HARKNESS.—On Oct. 26th, Thomas Harkness, M.B. Edin., of Derby, aged 78.

HISLOP.—On Oct. 30th, at Geraldine, Canterbury, New Zealand, Patrick Wood Hislop, M.D. Edin., son of the late J. Fowler Hislop, Castlepark, Prestonpans.

HOLMES.—On Nov. 1st, at Salisbury, Arthur Norman Holmes, M.B. Dub., aged 59.

MORGAN.—On Oct. 30th, at Beckenham, Llewellyn Arthur Morgan, M.D. Durh., M.R.C.S. Eng.

RICHARDSON.—On Oct. 27th, at Portinscale, Keswick, after a short illness, William George Richardson, M.B. Durh., F.R.C.S. Eng., aged 72.

ROE.—On Nov. 1st, at Shipton-under-Wychwood, Oxford, Edwin E. W. Roe, M.R.C.S. Eng.

SEVI.—On Oct. 24th, 1935, suddenly, Joseph Sevi, M.R.C.S., L.R.C.P. (of Paris and London), docteur en médecine, lauréat de la faculté de médecine de Montpellier, ex-interne en médecine de l'Hôpital Rothschild de Paris. At 104, Cazenove-road, N.16 (formerly of Upper Clapton-road, E.5). Beloved son of Mrs. S. Sevi and the late Reg. M. Sevi. Communications to 48A, Upper Clapton-road, E.5.

THOMPSON.—On Oct. 31st, at a nursing home, London, Charles Herbert Thompson, M.D. Dub., M.R.C.P. Lond., formerly of Harristown, Rathdowney, Queen's Co., Ireland, aged 78.

WINTER.—On Nov. 2nd, at Dublin, William Arthur Winter, M.D. Dub., B.A.O., Physician to Stevens' Hospital, Dublin, ex-President, R.C.P.I.

YOUNG.—On Oct. 30th, at the Essex County Hospital, George Young, M.D. Zurich, and New York State, M.R.C.S. Eng., of Colchester, aged 60.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

PHARMACOLOGICAL ASPECT OF
DIGITALIS THERAPY *

BY A. FRAENKEL, M.D.

HEIDELBERG

DIGITALIS was being used as a therapeutic agent long before the time of Withering¹ but the specific indications for its application in disease had not up to then been properly recognised. And Withering's conception of its cardiac action was by no means immediately accepted. Indeed, almost a hundred years went by before it could be said that the majority of physicians, both on the continent and in England, were making use of this conception in the practice of their profession.

Belief in the essential correctness of Withering's view arose not from the publication of a new edition of his classical monograph, nor from its translation into French and German. It sprang rather from the experimental work of clinicians who at that time were beginning to take an interest in physiology, and from whose investigations a new branch of medical science was being initiated: pharmacology. Indeed, pharmacology, in its interest in the isolation of active principles and in the investigation of the mechanism of action of old-standing remedies, has always given a privileged position to digitalis; and in spite, or rather because, of this historical development, clinical medicine has accepted the results of pharmacological investigations in so far as the mode of action of this drug is concerned. When, however, we look for the close application of this knowledge in therapeutics, we find clinical medicine still adhering strongly to traditional methods in the use of digitalis. This is especially so with general practitioners who feel disinclined to deal with experimental results which have accumulated during a long period of time, and, with the knowledge so gained, to proceed towards a rational use of digitalis in medicine.

Nevertheless, it should be possible to free the methods of use of digitalis from empirical tradition, and to ensure the same degree of accuracy in administering digitalis to patients as is demanded in a pharmacological experiment on the lower animals. In trying to do this we have of necessity to dispense with the customary galenical preparations and their many substitutes, and in addition to change the usual route of administration.

Route of Administration

Numerous experiments, originating in clinical experience, have shown that the effect of digitalis when given by mouth is decreased as a result of its reactions with the acid gastric juice and the intestinal alkali. Moreover, absorption is inhibited owing to the surface activity and adsorption of the drug. Consideration of these properties makes it clear that the effect produced by the drug at its specific seat of activity is both weakened and delayed after oral administration, and that the degree of this depression and delay will show large variations when different preparations of the drug are employed. Great as this loss in activity following oral administration in normal animals may be, it becomes increasingly so

in patients under the pathological conditions of circulatory failure; indeed, under such conditions the loss becomes incalculable. With oral administration, even when pure substances are used, the production of quantitatively predetermined effects becomes impossible. By the rectal route these sources of error, although diminished, are not entirely removed, and the local irritative effect produced by all digitalis glucosides excludes intramuscular and subcutaneous injection as means of giving this drug. The only suitable way then, of administering this valuable remedy quantitatively to the heart, is by intravenous injection, the essential requirements for scientifically conducted experiments being the same whether these experiments are performed on animals or belong to the field of experimental therapy.

The unrestricted prohibition which even pharmacologists placed on the intravenous administration of drugs had been shaken as early as 1890 by Baccelli and Landerer, long before the introduction of strophanthin therapy, and it should have been entirely removed by the general adoption of this route in the giving of salvarsan. In spite of this, however, objections have been raised repeatedly to the application of an essentially laboratory technique to therapeutic practice. Such objections are clearly invalid in view of the fact that my pupils and I during the past 25 years have carried out tens of thousands of intravenous injections of strophanthin without any of the dreaded complications having arisen. Confirmation of such freedom from danger is being received from every side since the dosage has been chosen according to certain rules established by my co-workers and myself, and since practitioners have made themselves familiar with the technique of administration.

Specificity of Action

Apart from specificity of action, the essential conditions for intravenous administration of a drug are solubility in water and stability of the watery solution. In so far as specificity of action is concerned, all digitalis glucosides comply in their fundamental characteristics with this condition. Recent developments in the chemistry of digitalis have revealed close relationships between the different glucosides, and this "Digitalis-monotonie"²—to use Sträub's expression—explains to some extent the similarity of their pharmacological actions. We are indebted to Cloetta,³ Windaus,⁴ Jacobs,⁵ Stoll⁶—to mention but those who have made the greatest contributions in this field of chemistry—for having supplied the analytical proof of the similarity in chemical structure of the whole pharmacological group. All these glucosides can be split by hydrolysis into a sugar-free organic compound—the genin—and one or more carbohydrate molecules. The similarity in chemical constitution is confined, however, to the genins, the genin of strophanthin—strophanthidin—having the same number of carbon atoms as that of digitoxin, namely, 23; the former differing from the latter only in the possession of two hydrogen atoms more and two oxygen atoms less. Greater difference occurs, however, in the structure of the sugars with which the genins are combined. The genins of the glucosides of *Digitalis purpurea* (glucosides of the first order) are combined with two or three molecules of digitoxose, a methyl pentose which occurs only in plants, and which can be broken down by the human organism only with difficulty. On the other hand, the sugars.

* A lecture delivered before the British Pharmacological Society at its meeting in Cambridge on July 5th, 1935. The observations and experiments on which the lecture is based are published more fully elsewhere.²²

of the digitaloids (glucosides of the second order, such as strophanthin, adonis, scilla, &c.) are easily decomposed in the animal organism since they are for the most part pentoses and hexoses. The carbohydrate of K-strophanthin, for instance, is a disaccharide consisting of glucose and cymarose both of which are readily soluble in water. G-strophanthin, or ouabain, contains the methyl pentose rhamnose which is far less soluble in water.

In spite of the "monotony" of chemical constitution which the genins exhibit, and the qualitative similarity in the effects which they produce, wide differences are observed in their quantitative actions, differences which Straub ascribes to the structure of the carbohydrate component of the molecule. It was only by keeping in mind these differences that the possibility arose of choosing a compound for intravenous injection which should prove most suitable for the development of a new method of treatment. I was guided in this choice by the results of experiments on cats⁷ in which were compared the degrees and duration of action of the different members of the digitalis family. Slowing of the pulse-rate being chosen as the criterion of action, the effect of glucosides of the first order was found to occur more slowly and to last longer than that of the glucosides of the second order. In the case of the latter the action both appeared and disappeared rapidly, and in contrast with what is found with digitoxin, the action could be maintained by repeated injections without there appearing any toxic effects attributable to cumulation of the drug. Cumulation, therefore, proved to be least with the digitaloids, and

antrhin, since it proved to be less toxic and more easily soluble than G-strophanthin.

Fig. 1 shows in a schematic way the difference in the degrees of cumulation with digitoxin and strophanthin when repeated and individually effective doses of each drug are given at constant intervals of time. As can easily be seen the toxic range of concentration is more readily attained under these conditions with digitoxin than with strophanthin. Hatcher⁸ has since repeated my experiments on cumulation, using an improved technique, and has confirmed my observations. But the scientific reason for the empirically discovered superiority of certain glucosides was only made clear by Straub's⁹ fundamentally important work on the varying degree of fixation of the digitalis glucosides by the tissues, work which found extension in the recent investigations of Fromherz and Bauer¹⁰ and of Weese and Dieckhoff¹² dealing with certain after-effects connected with cumulation. Büchner¹¹ pointed out the similarity between these late effects and changes in the heart muscle due to an impaired coronary circulation, and Fromherz showed that big doses of digitoxin did not, as Hatcher believed, lead to a fixation of digitoxin by the heart, lasting for several weeks, but produced irreparable and morphologically detectable injury to the heart muscle, the result, presumably, of coronary insufficiency.

Therapeutic and Toxic Cumulation

The key to the experimental differentiation between therapeutic and toxic cumulation was provided by Weese and Dieckhoff¹² when they showed on the one hand that therapeutic doses of the glucoside increased the isolated heart's capacity for work and its period of survival, and inhibited the processes of fatigue; and on the other, that toxic doses, themselves leading to morphological changes in the muscle, decreased the capacity for work and accelerated the processes of fatigue. In spite of this, however, the period of survival of such injured hearts was prolonged to the same extent as was that of hearts treated with therapeutic doses. Now the effects of these delayed injuries from digitoxin—first detected by Fromherz—had also occurred in my own experiments but I had not properly realised their significance. Even at that time, however, it struck me that the effects were to be seen only in animals treated with digitoxin, those treated with strophanthin for the same period never succumbing as the result of its administration. Subsequent experimental investigations have shown that the digitaloids, and especially the strophanthins, are fixed to the heart for so short a period that a therapeutic dose is eliminated within 24 hours, and in so giving a concrete reference for my own observations, have provided knowledge upon which the treatment of heart failure by the method outlined by myself and critically investigated by others, can be rationally based. It remains to add, as a matter of detail, that amongst the strophanthins the crystalline product from strophanthin gratus is more toxic than the amorphous compound obtained from strophanthin Kombé. This fact was clearly demonstrated by Hatcher and Eggleston,¹³ who were able to show in experiments on cats that, in order to cause vomiting it was necessary to inject intravenously 49 per cent. of the minimum lethal dose if G-strophanthin was used, whereas so much as 65 per cent. was necessary in the case of K-strophanthin.

The chemical and pharmacological investigations to which I have referred, as well as the knowledge which had been obtained with respect to the muscular and vagal actions of the drug, presaged a clearer

FIG. 1.—Differing cumulation of effect with digitoxin and strophanthin.

the absence of this phenomenon seemed to me an essential condition for the successful development of the intravenous method in treatment with glucosides.

The narrower choice among the digitaloids now fell on that group in which not the diuretic action, as in the case of adonis and scilla, but the cardiac action preponderated. From the two strophanthins which were available at that time, I chose K-stroph-

understanding of the principles of digitalis therapy. But such was only attained when pharmacology began to use, as a basis of interpretation, the law of the heart, discovered and so clearly enunciated by Starling,¹⁴ and when Anitschow and Trendelenburg¹⁵ and Krayer¹⁶ turned to the study of the therapeutic action of digitalis on the injured heart. Now about the same time as these pharmacological experiments were proceeding, a study of the circulation rate and circulating volume of blood in patients with varying degrees of functional impairment of the heart was being undertaken by clinicians and experimental pathologists, using the newer methods—gas-analysis (Barcroft, Grollmann) and physical (Broemser)—with which physiology had supplied them. A critical review of the results of such clinical investigations, carried out with different methods, admits no doubt that heart failure, as occurring after exertion in the milder degrees of functional impairment and during repose in the severer, is associated with a diminished stroke volume and a decreased output per minute, to which are linked, as secondary effects, changes in the volume of circulating blood.

Digitalis and Strophanthin

The intravenous administration of strophanthin, which had been adopted in the meantime, made it possible to study the effect of digitalis upon the course of these processes in man with methods as exact as those used in experiments on animals. Only patients with severe dyspnoea have to be excluded from such investigations. Now the experiments of Lauter and Baumann,¹⁷ Kroetz,¹⁸ Stuart and Cohn,¹⁹ and of my pupils Herzog and Grasmann,²⁰ leave no room for doubt that the main effect of digitalis in heart failure is an increase in the stroke volume and a change in the distribution of blood resulting from the increased circulation rate. Such an effect can be obtained with no other drug. The absence of appreciable effect on the healthy, as on the diseased heart when functionally compensated, and its appearance after minute doses in decompensation, may perhaps be explained in part by the intramuscular development of a specific sensitivity to digitalis in this latter group. For it is known from Weese's²¹ experiments that the intravenous injection of the glucoside is followed by the fixation of about 10 per cent. of the dose by the heart. If, as has been done by Clark,²² we calculate the amount of strophanthin fixed per gramme of heart muscle, the astonishing fact is revealed that 1 g. adsorbs at most 0.002 mg. of the drug. If, moreover, we assume that a compensated heart has undergone an increase in weight by 50 per cent., and if we further take into account the fact that one-tenth of the lethal dose has a detectable effect upon the diseased heart exhibiting a high sensitivity to digitalis, we arrive at the conclusion that the concentration in which digitalis acts is of the same order as that found in the case of the hormones.

To the question whether or no there arises a specific increase in sensitivity to digitalis when the heart fails,

FIG. 2.—To show typical dehydration by means of strophanthin in a case of severe heart failure after treatment with digitalis by mouth had been found unsuccessful.

no definite answer can as yet be given, owing to lack of clinical and especially experimental evidence. Weese points out that since the minute output of the "decompensated" heart is diminished, the possibility arises of a greater proportion of the total strophanthin injected reaching the coronary system and being fixed by the heart muscle.

The fact that disagreement in the theory of strophanthin therapy is associated with unanimity as regards the practical success of treatment with the drug, shows that much still remains to be accomplished by clinical investigation. Unfortunately we still lack methods which are easily applicable in everyday practice for the estimation of stroke volume and minute output. It is true that the physician finds a possible indication of these values in measurements of systolic, diastolic, and pulse pressures. In addition X ray photography and measurement of the venous pressure (the latter rightly emphasised by Lewis) are at his disposal for assessment of the degree of heart failure and of its therapy. Here, however, I should like to invite attention to two further methods of value in this connexion.

First, the daily measurement of body-weight excludes the possibility of neglecting the extrarenal loss of water—an error which easily occurs if only the urine output is determined—and indicates by direct means the day on which the removal of oedema fluid is completed, and so the time when the minute volume has in all probability reached its optimum. Exact observation of this kind enables us to avoid overdosage and at the same time, by gradation of the dose within 0.1 mg., to control accurately the rate of fluid removal, and so to delimit precisely the period allowed for complete elimination of the retained water; a realisation of the therapeutic ideal of obtaining optimal effects from the smallest doses. Fig. 2 illustrates this in the case of a patient who showed no improvement from treatment with digitalis by mouth.

bigeminus) supervened. Fig. 5 shows that after a short period of observation without medication, the loss of water was initiated by salyrgan and the failure of the heart abolished by strophanthin. It may be added that we were able to avoid the appearance of pulsus bigeminus as well as other signs of toxic action, in spite of the fact that the patient received in the course of 60 days 25 injections of strophanthin of about 0.3 mg. each, amounting to 6.3 mg. of the drug. In addition a total of 16 c.cm. of salyrgan in 12 injections was given. The elimination of water resulted in a decrease of 21 kg. in body-weight,

means—Withering's therapy retains its position in the treatment of heart failure where such is of not too severe a degree or of not too long a standing.

I wish to thank the editors of "Strophanthintherapie" and the "Verhandlungen der Deutschen Gesellschaft für innere Medizin" and the publisher, Herrn Julius Springer, Berlin, for permission to reproduce the Table and Figs. 3, 4A, 4B, and 5 from papers by Dr. Herzog and myself.

FIG. 5.—To show typical dehydration by means of strophanthin and salyrgan in a patient with old-standing oedema and in whom signs of overdose with digitalis had previously appeared.

a fact which shows that the normal weight of the patient had increased by as much as 40 per cent. during the development of the failure. Notice should also be taken of the fact that the elimination of oedema fluid under the influence of the diuretic salyrgan, acting on the tissues and kidney, occurs characteristically in steps, whereas during the quantitatively controlled treatment with strophanthin this loss proceeds steadily. This can be seen especially well if Fig. 5 is compared with Fig. 2.

From the first experiments with digitalis on the frog's heart to the more recent and complicated investigations on the action of digitalis on the heart and circulation of the mammal, the path has been long and tiresome. We must not be surprised, therefore, if the practical application of pharmacological research to the reduction of the suffering and to the prolongation of the lives of patients with heart disease, takes long to achieve. This attempt, however, to evolve a rational digitalis therapy from a knowledge of experimental pharmacology, and to describe the peculiar importance of the intravenous route in connexion with the glucoside which is most suitable for this mode of administration, is not to be regarded as a revolt from the customary empirical use of preparations of digitalis by mouth. By no

OBSTETRIC PRACTICE OF THE FUTURE*

By MILES H. PHILLIPS, M.D., F.R.C.S. Eng., F.C.O.G.

EMERITUS PROFESSOR OF OBSTETRICS AND GYNECOLOGY,
UNIVERSITY OF SHEFFIELD; CONSULTING SURGEON TO
THE JESSOP HOSPITAL FOR WOMEN, SHEFFIELD

At the present day it is often stated that all is not well with obstetrical practice in this country; nor is it in fact perfect in any country. There are many factors involved, many openings for errors in judgment, even by the competent specialist working under the best conditions. Much greater are the difficulties and more frequent the occasions for faulty practice in the surroundings in which so many women are delivered.

Factors Favouring Institutional Midwifery

I propose to examine two considerations, which in our evolving civilisation have come to the front, and, I believe, will prove to be fundamental factors in directing the practice of obstetrics in the future. These are (1) the increasing demand by women themselves for the relief of pain at childbirth, and (2) the desirability of lessening so far as possible the traumata of parturition both maternal and foetal. The most satisfactory and successful means of providing these safeguards will, in my opinion, require and lead to the provision of more and more lying-in beds in hospitals, voluntary, municipal, and private. The midwife and the obstetrician of the future, working in coöperation, will, it appears to me, conduct more and more and finally all deliveries, in specially equipped institutions. However great may be the supposed advantages of domiciliary midwifery in present-day practice, they will be supplanted, I believe, by the benefits to all concerned which will follow the widest possible extension of institutional midwifery.

DEMAND FOR RELIEF OF PAIN IN CHILDBIRTH

All must agree that an increasing number of women desire the relief of pain in childbirth. It is not only fair and humane to recognise this demand, but sound in principle to accede to it. By preventing or dispelling severe pain in childbirth, both physical and mental shock with their harmful consequences, immediate and remote, are obviated. However, the successful methods so far available require constant attention by nurse or doctor, and often doctor as well as nurse, and both of these must be specially experienced in the choice and control of these pain-relieving drugs. One must also admit that the natural course of labour is often prolonged.

In domiciliary practice the achievement of really effective relief from pain demands too much of the family doctor's time, and so may easily lead to interference in the labour which may be premature and harmful, or, even if well chosen and advantageous, cannot, with due regard to immediate safety or future comfort, be carried out in the ordinary domestic bedroom. The necessary space, assistance, and even equipment may be, one or all, lacking.

My second consideration is, the avoidance of birth trauma.

AVOIDANCE OF BIRTH TRAUMA

I am not concerned now with the prevention of severe trauma of mother or foetus by the employment

of induction of labour, or of Cæsarean section in cases of pelvic contraction or other instances of marked disproportion between foetus and pelvis. It is already generally recognised that such procedures are most safely practised in maternity hospitals. I have in mind the avoidance of less severe but permanent damage to the pelvic floor and perineal body, and at the same time the prevention of harmful compression of the foetal head by prolonged pressure on the resistant perineum. For a number of years I have been more and more impressed by the advantages to mother and infant of the operation of episiotomy. The increasing use of analgesics and anaesthetics has no doubt helped to bring this about. When they are used the natural forces in labour are often hampered, as I have already stated, and natural expulsion of the foetus is liable to be dangerously prolonged or even completely frustrated.

The Advantages of Episiotomy

I am therefore in full agreement with Prof. Leyland Robinson¹ when he states, in a recent paper on the treatment of genital prolapse, that he is "convinced that prolonged pressure reduces the nutrition and sometimes destroys the tone of the supporting pelvic floor and perineal muscles, and that excessive conservation may be responsible for the development of prolapse. A well-judged episiotomy designed to cut short this harmful period of waiting and dangerous pressure, is," in his opinion, "a prophylactic measure of real value and one that ought to be employed more frequently."

Prof. Robert Goodall² of Montreal has also written recently, and very convincingly, in favour of episiotomy followed by immediate and careful suture. After ten years' experience of the conservative policy of non-interference, he has come during the succeeding ten years to practise prophylactic intervention near the end of the second stage of labour with definite objects in view: (1) reduction in the amount of damage to the abdominal wall; (2) minimal damage to the supports of the uterus, bladder, and rectum; (3) a completely restored pelvic floor; (4) great reduction in the number of stillbirths, and I think one can fairly add a probable lessening of mental morbidity in childhood and adult life.

In regard to this last consideration, it is significant that Dr. Leonard Findlay,³ who has devoted much time to the study of the causation of mental deficiency, does not think that it is to any large extent hereditary. On the other hand he believes that in the larger proportion of cases it is due to difficult birth, and he draws attention to the special liability of the first-born to this defect. This view is held by other authorities: Dr. R. D. Clarkson,⁴ of the Royal Scottish National Institution for Mental Defectives at Larbert, considers it "cruel and inaccurate to maintain that mental deficiency is hereditary": "Very few of the parents of the patients in the Larbert Institution are certified defectives." "John Thomson, Leonard Findlay, and Charles McNeil have all," he states, "proved that heredity plays only a small part in the aetiology of mental deficiency," and Dr. Clarkson "is quite certain that a very large proportion of the cases are caused by injury to the brain at birth." Excessive moulding of the head from prolonged pressure on it by a resistant pelvic floor must occur to the experienced obstetrician as one likely cause of this calamity.

Central episiotomy comprises a precise and predetermined division of the fascial septa separating the perineal muscles, and even of the vagino-rectal sheet of fascia which runs from belly to belly of the

* The second part of a paper entitled *Men-Midwives Past and Future*, which was read before the Bristol Medico-Chirurgical Society on March 13th, 1935. The first, historical, part was published in the *Bristol Medico-Chirurgical Journal*, 1935, lii., §3.

levatores ani. This is in place of bruised and crushed lacerations of the fascia and muscles—generally open and obvious injuries, but not seldom subcutaneous and therefore invisible. When the episiotomy wound has been sutured in layers, with the precision which adequate assistance and good light make possible in a clean-cut wound, the woman can return to her domestic or other duties, unhampered by the constant discomfort produced by sagging pelvic floor and viscera. Junior students watching the operation of repair are surprised to see the thickness of the perineal muscles, which ranges from one-third to half an inch, instead of the "slender fasciuli" which text-book anatomists have taught them to expect. Surely it is better for the woman to have such a wound repaired in this thorough way, than to have to submit to the formal plastic operation, expensive in both time and cost after years of increasing discomfort.

If we recall the preparations, precautions, and personnel which are found necessary to ensure success in these belated plastic repairs, and contrast them with the disadvantageous circumstances in which the recently torn perineum and vagina are more or less ineffectively stitched, it seems clear that this wide gap between mismanagement and efficiency must be bridged. More than half the beds in my gynaecological wards are in constant use by patients recovering from the plastic repair of old obstetrical injuries; more than half the time I spend in the operating theatre is occupied in repairing the damage which parturition has inflicted on the genital passage. I will grant that perhaps a fourth of these operations are concerned with injuries to the cervix and upper vagina especially, which have often followed premature and injudicious interference in parturition. These are often enough no doubt due more or less directly to the difficulties of time and place which surround ordinary domiciliary midwifery practice. However, the majority of these repairs involve the perineum and pelvic floor. The rectocele resulting from the injuries inflicted during childbirth may cause daily discomfort and produce much mental distress and even neurasthenia. This damage should have been prevented by adequate management in the hour of labour. Such effective care, I submit, can only be guaranteed in a properly equipped maternity hospital—not necessarily a large one—with all the facilities of equipment and personnel which are rarely if ever available in the woman's own home.

It is also my experience that episiotomy at the right moment, is often followed by natural unaided expulsion of the foetus. The right moment is in the latter part of the second stage, as soon as it is evident that the perineal body is holding back the foetal head. The last and probably most harmful degree of moulding, which might have resulted from the most careful extraction of the head by means of forceps, may thus be avoided.

It is of interest to contrast, by gauging with finger and thumb, the thickness and tonicity of the perineal body in women after a properly repaired episiotomy, and in other women after a natural delivery in which there had been no surface tear, but subcutaneous laceration followed by retraction of the muscle. Such laceration leaves a thin and toneless perineum and is often followed by the formation of a rectocele and a lack of support to the lower part of the anterior vaginal wall on which rests the urethra. The perineum restored after episiotomy will often, of course, require the same care at a subsequent labour, a possible disadvantage in the old days of large

families and frequent childbearing. The present-day smaller and wisely spaced family does not focus attention on this consequence. On the other hand, the modern mother has probably a higher standard of comfort and prefers to feel as sound and "comfortable below" as she did before her child was born.

Extension of Institutional Practice

I have given the two main considerations which lead me to advocate an extension of institutional midwifery practice. Many others could be advanced, not the least impressive being contained in the following extract from a recent letter⁵ by a young general practitioner, in condemnation of the handy-woman. He says:—

"Not infrequently I have had a filthy woman of abysmal ignorance and ineptitude as helper, a cottage room bunged up with old furniture, clothes, bric-à-brac, no hot water, a candle to work by, and in these surroundings have had to do a difficult forceps, first giving the anesthetic, then hastily scrubbing up and performing the operation—with one eye on the patient, one on the job, and any spare glances to keep the 'Gamp' from interfering."

Such reasons as these are already greatly influencing the general public as well as many maternity nurses and medical attendants, the result being an increasing demand for maternity in-patient treatment throughout the country.

The number of maternity beds available in municipal institutions, in voluntary hospitals, and in private nursing-homes is rapidly increasing. It is not possible to give exact figures for the whole country, but Sir George Newman in his Annual Report for 1933 recognised the increasing demand and its consequences; he gave a table showing that in the city of Manchester the proportion of the total number of births, taking place in hospitals and registered nursing-homes, has risen year by year from 10.9 per cent. in 1924 to 40.36 per cent. in 1933 (it was over 50 per cent. in 1934). He remarks that "This may fairly be regarded as representative of the present tendency in urban areas." Most of us are aware that this tendency is also evident in the smaller towns, and even in country districts the village midwife and the family practitioner find that many women will readily avail themselves of a maternity hospital as soon as one is provided in the adjacent market town. Both midwife and doctor quickly realise that such an arrangement is helpful.

Modern housing, which usually provides more but markedly smaller rooms, and the increasing difficulty in obtaining domestic assistance exert an influence in the same direction. In some places the demand for this accommodation greatly exceeds the supply.

LIMITATION OF SIZE OF INSTITUTIONS

This is not the occasion on which to consider in detail the construction of these hospitals. They would vary in size from the large urban hospital of 100 to 200 beds, adapted not only for the comfort and safety of parturient women, but also for the purposes of teaching and research, to those of 10 to 20 beds, perhaps more or less closely associated with cottage hospitals, to serve country districts.

There are reasons for holding that there should be a definite limitation in size; it is likely that those hospitals not exceeding 100 beds would give better results than those with more. Whatever the additional cost might be, it would be wiser for a large urban area to provide two or even more maternity hospitals rather than one beyond the capacity of personal control by the obstetrician in charge.

I can also picture a small lying-in hospital as an

essential part of the lay-out of a modern garden city, or of the new residential areas which are springing up so rapidly on the outskirts of all large cities; and possibly, even as a standard provision in the large residential flats which are bound to arise in the central areas of the largest cities. By such means would be avoided the great drawback of a forbidding distance between the woman's home and her lying-in bed.

No one knows better than I that many experienced obstetricians look with great disfavour and even alarm on a wide extension, such as I have outlined, of institutional as opposed to domiciliary midwifery. The increased risk of the spread of puerperal sepsis is a very real one; one has only to read the history of the subject to realise this danger.

The general surgeon has also had this problem of septic infection to face, and he has overcome it with almost complete success. With regard to child-bed infection the problem is, in my opinion, only apparently a more difficult one. As soon as the precautions that have been found necessary by the general surgeon are carried out conscientiously and in minute detail by fully trained obstetricians and midwives, so soon shall we see a marked fall in the incidence of puerperal sepsis.

However, the responsibility involved in bringing together numbers of lying-in women is a very great one—there are loopholes for failure, it is human to err, and the onset of labour cannot be postponed (as most surgical operations can) when the woman is suffering from general ill-health or some other infective condition. I have here in mind especially infections of the nasopharynx.

ONE-BED WARDS

This special possibility of infection leads me to advocate that each woman in labour, or shortly expecting labour, should be admitted to a single-bedded room of sufficient size to enable a straightforward delivery to be comfortably carried out in that room if so desired. In other words, the hospital bed accommodation should be almost if not entirely "private" and not so to only a small extent as we find in nearly all maternity hospitals—municipal as well as voluntary. This is what can be done in our private maternity homes with a complete absence of serious puerperal infection.

The idea is a very old one; in 1773 Charles White⁷ of Manchester, who wrote so wisely on the management of lying-in women, laid it down that "it would be still better if every woman was delivered in a separate ward, and was to remain there for a week or ten days till all danger of this fever was over." However, I would modify this opinion of Charles White, to which he was driven by consideration of the terrible epidemics of puerperal fever which broke out from time to time in the lying-in hospitals of his day. It would be allowable four or five days after delivery, all being well, and when greatly desired for social or financial reasons, to transfer the woman, preferably bed and all, to a small ward with not more than three or four patients.

I feel convinced that this ideal plan would not be so impracticable as it may at first sound, and it would obviously lessen some of our other difficulties, for example the shortage of accommodation, with its evil consequences, which arises when large wards are being cleaned, and also the danger of imported infection by visitors.

THE PERSONNEL REQUIRED

It must have become obvious that I expect the "man-midwife" of the future to have had a special

training in obstetrics and especially in surgical obstetrics.[†] This will necessitate post-graduate residence in a maternity hospital, and the obtaining of a special diploma as evidence of proficiency in operative midwifery. The larger hospitals must be controlled by a resident master-obstetrician and gynaecologist. Under him will work a whole-time staff of large experience, who will be directly responsible for all major operations. They will also control and supervise the routine work of the midwives, who, in the near future, will be compelled, I am convinced, to take a much longer and more thorough course of training than is the rule at present.

In the smaller district and country hospitals, it will probably be found necessary for a family doctor, who is sufficiently interested in obstetrics to have qualified himself by special post-graduate hospital experience, to attend these patients with the coöperation of the highly trained resident midwives, aided of course by a colleague when an anaesthetic is required. In other words, before undertaking this responsible work he will have to have gained experience and skill, after graduation, by a long period of residence in a maternity hospital, and not, as has been too long the case, by striving to overcome the difficulties of domiciliary practice, often, I readily grant, with surprising success, but sometimes at the expense of the parturient woman or her child.

Would this revolutionary change be such a grave hardship as some imagine? I doubt it. Many of my doctor friends have told me of their dislike for midwifery, with its anxieties and exactions; that they undertake as little as possible, and that only in order to benefit their general practice.

Surely such an attitude of mind is a very grave handicap. I have long realised this. My own views could hardly be better expressed than in the following sentences which I have extracted from a recent letter—again from a general practitioner.⁶ He says:

"Probably most general practitioners would admit that they consider midwifery the most irksome of their many duties. Either it interferes with the ordinary run of work or it deprives them of much-needed hours of sleep. . . ."

He suggests that:—

"The medical profession should organise its own midwifery on the following lines. Let the country be divided up into districts. In each district the general practitioners would agree to hand over all their midwifery to someone who wishes to specialise in this work and in gynaecology, and who, in turn, would guarantee to practise solely as a gynaecological surgeon and specialist in midwifery. . . . The general practitioner would be relieved of much night work without losing his family practice."

In addition, he points out, "neighbouring districts could combine to equip up-to-date maternity and gynaecological hospitals." The author of this letter and I, looking at the problem from different angles, would seem to have come to very similar conclusions. I feel sure he would agree with me that this great change will have to be gradually evolved.

CYCLOPROPANE ANÆSTHESIA

A REPORT BASED ON 250 CASES

By STANLEY ROWBOTHAM, M.D. Durh.

BEING THE ANÆSTHETIC STAFF OF THE CANCER HOSPITAL, LONDON

Our knowledge of the chemistry and physical properties of cyclopropane has been gained chiefly from America; it is to Waters and Schmidt of Wisconsin that we are indebted for its introduction and establishment as an anæsthetic agent.

First prepared by the German chemist Freund in 1882,¹ it was not until 1929 that its anæsthetic properties were investigated by Lucas and Henderson at Toronto.²⁻⁴ In October, 1933, a preliminary report on 447 cases of cyclopropane anæsthesia from the University of Wisconsin medical school to the Annual Congress of Anæsthetists focused the attention of anæsthetists all over the world upon the new gas.⁵ It was introduced into England in December, 1933, by Dr. R. M. Muir of Cape Town, who brought a cylinder with him from America and generously consented to administer it to several cases at the Cancer Hospital.

Cyclopropane or trimethylene is an isomer of the hydrocarbon gas propylene. Its formula shows its cyclic structure. It is heavier than air (spec. gravity 1.46) and is almost insoluble in water, but very soluble in lipoids (1 c.cm. olive oil dissolves 103.5 c.cm. cyclopropane).³

Being an inflammable gas, it is explosive in mixtures with air or oxygen. In air the flammability limits are 3 per cent. to 8.5 per cent.; but in oxygen 2.5 per cent. to 50 per cent. (18.2 per cent. cyclopropane with 81.8 per cent. O₂ gives a maximum explosive violence). In nitrous oxide the limits are 3 per cent. to 28 per cent. Hence cyclopropane is capable of exploding as usually administered for anæsthetic purposes. Precautions must be taken, as with other inflammable anæsthetics, to eliminate sources of ignition and therefore its use with the cautery or diathermy is definitely contra-indicated.⁶ It has a characteristic pungent smell not unlike that of ethylene but is not irritating when inhaled in the concentrations necessary for producing anæsthesia.

Cyclopropane can be compressed into cylinders without undergoing chemical change. It liquefies at a pressure of 75 lb. and a 100-gallon nitrous oxide cylinder will hold about 62½ imperial gallons of cyclopropane.* Such a cylinder at present costs £9 in London, but we understand that the gas manufactured in this country will cost about £6 5s. for a similar amount, or 2s. per gallon.

Cyclopropane is prepared by the reduction of trimethylene bromide with metallic zinc in alcoholic solution. The Ohio Manufacturing Company were the first to develop its manufacture and purification, and it was with gas manufactured by this company that the investigations at the University of Wisconsin were carried out; the greater proportion of the gas used for our investigation also being obtained from this source. We have lately obtained samples

manufactured and presented to us by Imperial Chemical Industries Ltd. This has not quite so pungent a smell as that imported from the United States, and after tests with laboratory animals we have employed it at the Cancer Hospital. We are satisfied that it is as potent an anæsthetic agent as that obtained from America; that it is no more toxic, and that it is more pleasant to inhale.

The conclusions reported in this paper are based on an experience of 250 cyclopropane administrations carried out during the past eighteen months, of which 76 were in private practice and the remainder at the hospital.

PROPERTIES

Cyclopropane is a powerful anæsthetic of the potency of chloroform but without its toxicity and without its depressing effect on the circulation. In many of our cases we have found an increase of the systolic blood pressure, and it seems remarkable that this has not been commented upon by the early investigators in America, for we have observed it and checked one another's observations repeatedly. Shortly after administration starts the patient's systolic pressure rises 10, 20, 30 or more mm. Hg; a rise of diastolic pressure follows, but as a rule of less degree. If the anæsthesia be now lightened the pressure usually begins to fall, only to rise again on addition of more cyclopropane. The higher the concentration of cyclopropane the higher the blood pressure, even when the anæsthesia reaches almost to the stage of respiratory arrest; but in cases where the pulse becomes intermittent through overdose and also in those with shock the same continuous rise does not occur. Definitely we found more capillary bleeding than with other anæsthetics.

Waters and Schmidt state that there is no alteration in the coagulation time of the blood.⁷ With this our observations in 4 cases agree.

"Cyclopropane," they say, "is capable of producing narcosis when inhaled in concentration as low as 4 per cent. . . . the average concentration of cyclopropane for first plane, third stage anæsthesia (roving eyeball) was 7.4 per cent., while second plane (fixed eyeball, sufficient for a majority of abdominal operations) required an average of 13.1 per cent., and third plane, with intercostal paralysis, required an average of 23.2 per cent. . . . Fourth stage anæsthesia, or respiratory arrest, was produced with an average concentration of 42.0 per cent. When produced in the presence of high oxygen concentrations, such respiratory arrest has not been found to cause harm provided ample tidal exchange is artificially maintained."⁷

There appears to be a good margin of safety between 23 per cent. and 43 per cent., but in our opinion cyclopropane must nevertheless be considered a respiratory depressant. It is true that deep anæsthesia with consequent depression of the respirations is very easily and quickly attained, and the impression may at first be formed that the anæsthetic affects the respiratory centre more powerfully than is actually the case; but we have occasionally found patients (especially those who have received full premedication) cease breathing before muscular relaxation can be obtained.

One case was particularly instructive in this respect. The operation was a Cæsarean section on a healthy woman who was not in labour. No preliminary medication was given, and the amount of cyclopropane added to gas-and-oxygen was barely sufficient to produce second-plane anæsthesia. The mother breathed normally, but the child did not breathe for ten minutes, and then only after vigorous efforts at resuscitation. Eventually it breathed well, and neither the mother (who afterwards was deeply anæsthetised) or the child showed ill-effects.

* One ounce weight = 3½ imperial gallons of gas.

In low concentration cyclopropane is non-irritant; laryngospasm is caused only by inhaling very high percentages of the gas. There is no increase in the depth of the respirations and deep anæsthesia may be produced in a few breaths. There is very little increase in the pulse-rate. During induction therefore the greatest care and watchfulness must be maintained.

ADMINISTRATION

Premedication.—In most cases we followed our usual custom of giving omnopon, gr. 1/30 per stone of body-weight, an hour before operation. This dose is as a rule insufficient to cause much depression of the respiratory centre. Some patients were given intravenous Nembutal or Evipan, either alone or after omnopon, or omnopon and scopolamine. After this last combination there was considerable respiratory depression; indeed breathing usually stopped before the abdomen relaxed.

Apparatus.—For the sake of economy carbon-dioxide absorption technique was employed in nearly every case, but often the soda-lime absorbent was not brought into use until after induction, in order to obtain the benefit of the increased respiration. In some cases we even added CO₂ to stimulate deeper breathing and increase the rate of saturation, and often where respiration was unusually shallow no CO₂ absorption was attempted throughout the anæsthesia.

Most patients were intubated with a full-size tube, so that when necessary it was easy to continue respiration artificially by squeezing the bag. The deeper planes of anæsthesia were thus easily obtained and the patient remained in good condition so long as this was kept up.

At first we used the simplest apparatus possible: a well-fitting mask with Clausen's harness, a one-gallon rebreathing bag into which soda-lime was put when necessary, and two glass flow-meters which were specially graduated to measure up to 1 litre of gas in multiples of 50 c.cm. Lately we have used the McKesson apparatus with cyclopropane fittings and CO₂-absorption outfit, but have not found it so easy to use nor so economical of gas as our original simple apparatus.

At the commencement of *induction* the bag is filled with oxygen, the face-piece is firmly applied and cyclopropane then run in at the rate of 250 c.cm. per minute. After about a minute the rate is increased to 500 c.cm. or more, as may be necessary. The oxygen flow is now adjusted to about 250 c.cm. per minute—the quantity required by the patient is quickly ascertained—and after a period which may vary from one to five minutes, the cyclopropane flow is stopped completely. Induction is remarkably quiet and excitement is seldom seen. There is neither coughing nor laryngeal spasm, nor are respirations increased; they are in fact usually very shallow, especially when preliminary narcotics have been used. In these cases respiratory movements may even cease altogether without the supervision of true fourth-stage anæsthesia, for the patient is not completely relaxed. If full muscular relaxation is necessary the patient is intubated and respiration continued by squeezing the bag. The deeper planes (with relaxation) are thus easily obtained and the patient remains fit so long as the artificial respiration is kept up. Once relaxation is attained the mixture in the bag is weakened by addition of more oxygen, and spontaneous respiration usually begins very soon. The patient afterwards remaining relaxed although the concentration of cyclopropane respired has been considerably reduced. In most cases once the patient has been anæsthetised cyclopropane need be added

only at long intervals to make up for loss through the apparatus or to deepen anæsthesia if and when necessary.

PHYSICAL SIGNS

The signs of anæsthesia are exactly the same as those seen with other general anæsthetics, but the administrator who has been in the habit of depending upon the depth of respiration as an indication of the degree of anæsthesia may find himself somewhat at sea with the very shallow respiration of cyclopropane anæsthesia. Actually the degrees of respiratory paralysis are the same although much less obvious. In very early, first-plane, anæsthesia the eyes move. As the patient's respiratory centre becomes paralysed by the action of the gas the respiratory excursion becomes progressively less, until finally the diaphragm alone is carrying on the function of respiration. If the anæsthetic is further pushed diaphragmatic movement becomes more and more depressed until finally respiration is entirely arrested.

Except in cases which have received heavy premedication muscular relaxation occurs early and is very complete—owing, it is stated, to the full oxygenation of the muscles.

Usually the rate of the pulse neither rises nor falls with cyclopropane, but in a few of our cases (all of which we would consider as poor risks with other anæsthetics) changes have occurred in its character. There is sometimes an increase in the rate, but more often a slowing to between 50 and 60 accompanied by arrhythmia which may be due merely to extra systoles or to a true auricular fibrillation. It is remarkable that the beats often were not all of the same power; many which were felt at the apex did not come through when the sphygmomanometer cuff was blown up to within a few millimetres of the systolic pressure. Inflation of the lungs with pure oxygen, followed by reduction in the cyclopropane concentration, always stopped the arrhythmia; but we did not find that atropine had any effect upon it.^s

OVERDOSE

If excessive amounts of cyclopropane are used induction may be extremely rapid and the patient may pass into fourth-stage anæsthesia in a few breaths. This has to be prevented by careful control of the gas flow, but overdosage is easy if the anæsthetist has had no previous experience with cyclopropane. Apart from the advent of fourth-stage anæsthesia certain alterations in the pulse of several cases have led us to believe that cyclopropane is not so innocuous an anæsthetic as nitrous oxide or ethylene. It is lipid-soluble; and patients who have inhaled it in fairly high concentration for long periods have taken a considerable time to recover consciousness, often suffering from severe nausea and vomiting.

ELIMINATION AND RECOVERY

Recovery after cyclopropane anæsthesia is usually fairly rapid and without excitement or other undesirable sequelæ. Speaking generally, the duration of recovery depends on the amount of cyclopropane which has been inhaled and also on premedication. After the lightest anæsthesia, lasting only a brief period, the patient will regain consciousness as soon as he would after nitrous oxide and oxygen and with no more after-effects; but after a high abdominal operation, when he has been deeply anæsthetised for an hour or more, consciousness does not return for a considerable time. It must be remembered that in this type of case deep anæsthesia is necessary up to the end of the operation, in order

to allow the abdomen to be closed; hence desaturation of the tissues has hardly begun when the patient leaves the operating-table. In all but high abdominal cases, however, anaesthesia may be progressively lightened as soon as muscular relaxation has been achieved, and recovery of consciousness is thus made much more rapid. Many patients actually speak as the dressings are being applied. We have had no trouble with the breathing and the patient's colour remains good throughout the period of recovery.

Nausea and vomiting is not absent. It is definitely less than with ether but more than with gas-and-oxygen, even in cases which have only had light anaesthesia equivalent to that obtained with gas-and-oxygen.

On the whole cyclopropane affects the patient's metabolism very little; although there is vomiting in a fair proportion of cases there is no evidence of damage to liver or kidney.⁶ Waters and Schmidt state that the output of the kidneys is depressed during anaesthesia and shows a compensatory increase afterwards, as with ether and ethylene.⁷ The blood pressure, raised during the administration, usually

was 52, and he gave a 6 months' history of pain, vomiting, and rapid wasting. Weight 8½ st., haemoglobin (after blood transfusions) 66 per cent. After premedication with omnopon gr. 8/30 induction was uneventful. The patient was intubated, and relaxation, which had to be full, could be obtained only by artificially inflating the chest, the patient having ceased spontaneous respiration before relaxation was complete. Oxygen was running at 3 litres per minute and cyclopropane at 300 c.cm. per minute.

The abdomen had been opened about five minutes (this was about twelve minutes from the commencement of induction), and the bag was being squeezed rhythmically about 20 times a minute, when the patient became pale and the pulse vanished. The lungs were immediately inflated with pure oxygen, but all efforts at resuscitation (including heart massage and injection of adrenaline into the heart muscle) were in vain. Unfortunately we were unable to obtain a post-mortem examination. The case was a poor risk, and the heart was evidently unable to stand up to the stress of deep anaesthesia.

SUMMARY

After a fairly extensive trial we are of opinion that cyclopropane, despite its disadvantages, is a valuable anaesthetic and that it has properties not possessed

Group	Number of cases.	Nausea only.	Vomited.			Percentage of patients complained of nausea or vomiting.	Head-ache.	Restlessness.	Collapse.		Respiratory complications.	Died.
			(1)	(2)	+				Mild.	Severe.		
I.—Light anaesthesia ..	106	10	20	10	3	40.4	5	12	3	0	1	0
II.—Lower abdominal ..	44	4	8	3	2	38.6	0	5	1	1	0	1
III.—Upper abdominal ..	87	4	14	8	5	35.6	0	17	5	4	2	4
IV.—Toxic thyroid ..	13	0	4	0	2	46.1	1	1	2	2	0	0
—	250	18	46	21	12	—	6	35	11	7	3	5

falls to normal within about a quarter of an hour and (except in the presence of surgical shock) does not seem to swing below the patient's normal.

ANALYSIS OF CASE

The accompanying Table is an analysis of the cases on which this report is based. The groups it distinguishes were:—

I.—Light anaesthesia without relaxation. These cases included operations ranging from dental extractions and tonsillectomy to amputation of breast.

II.—For the most part comparatively short abdominal operations such as appendicectomy and hysterectomy. This group also includes 5 cases of nephrectomy.

III.—Long upper abdominal operations with a large proportion of gastrectomies, of which a relatively large number are performed at the hospital. They require careful handling from the anaesthetic point of view.

IV.—Toxic thyroid cases. These afford a good test for an anaesthetic agent, and for this reason they are grouped separately.

The cases which proved fatal may be summarised thus:—

1. Tumour of kidney .. Died 12 hours after of shock.
2. Oesophagectomy .. Died 2 hours after return to ward. fit until pneumothorax during operation. Cyanosed.
3. Carcinoma stomach and oesophagus. Died on operating table (see below).
4. Gall-bladder .. Died of pulmonary embolism.
5. Carcinoma gall-bladder. Died 3 days after. Bad risk. Jaundiced.

In Cases 1, 2, 4, and 5 the patient's death can hardly be attributed to the anaesthetic.

CASE 3 was a man with neoplasm of the stomach, high up and extending into the oesophagus. His age

by others. It seems to be chiefly useful for obtaining deep anaesthesia or for fortifying gas-and-oxygen temporarily. The latter is so innocuous that we see no reason to suggest that cyclopropane should replace it when light anaesthesia is all that is required.

One of the disadvantages of cyclopropane is said to be its cost. With the technique described we used about 2½ gallons for an hour's anaesthesia, which at present costs 7s. 2½d. Expense, therefore, can hardly be regarded as an objection, especially as the price of the gas made in Britain will be considerably lower. A real disadvantage is that of bleeding, and although we have used cyclopropane for breast and thyroid operations we prefer gas-and-oxygen for this purpose. In one or two cases in which the patient already had a high blood pressure cyclopropane has been given with great care and without ill-effects; curiously, the blood pressure rose only three or four points.

Induction is always pleasant for the patient, with no sensations of bursting, throbbing, or choking, such as are sometimes complained of with other anaesthetics. Although the odour of cyclopropane as it issues from the cylinder is not pleasant, patients are not aware of it during induction, nor do they complain of unpleasant taste or smell during the recovery period such as is associated with ether. We have never failed to obtain complete abdominal relaxation, although it has often been necessary to increase respiratory exchange by artificial methods. When this artificial respiration is resorted to it must always be borne in mind that one is dealing with an extremely potent agent which is not without its effect on the heart muscle.

The fact that cyclopropane is neither a respiratory stimulant nor irritant makes it necessary that the anaesthetist should exercise the greatest care in its administration; but in the hands of the expert we believe it to be an anaesthetic of great utility and value.

We wish to thank the house committee and surgical staff of the Cancer Hospital for making this investigation possible. The greater part of the cost of the gas and of the special apparatus was borne by the hospital; but we later received valued help from the Joint Anaesthetics Committee of the Medical Research Council and Royal Society of Medicine. This committee was responsible for the supply of several cylinders of the imported gas and, as the result of successful negotiations with Imperial Chemical Industries Ltd., has secured its manufacture in this country. We also desire to thank Messrs. A. Charles King Ltd., who undertook the troublesome task of importing the gas from America and made suitable apparatus for its use. This they did at cost and without profit.

WHOOPING-COUGH

THE DIAGNOSTIC SIGNIFICANCE OF BLOOD COUNTS

By NORMAN D. BEGG, M.D. Aberd., D.P.H.

MEDICAL SUPERINTENDENT, BOROUGH INFECTIOUS HOSPITALS, SOUTHERN-ON-SEA; LATE SENIOR ASSISTANT MEDICAL OFFICER, NORTH-EASTERN HOSPITAL (LONDON COUNTY COUNCIL); AND

MARGARET F. COVENEY, M.B. Sheff., B.Sc.

ASSISTANT MEDICAL OFFICER, NORTH-EASTERN HOSPITAL

Two laboratory methods are commonly used in the early diagnosis of whooping-cough. The first consists in the isolation of the bacillus of Bordet and Gengou on specially prepared blood plates, and appears to be of established value in the earliest stages of the disease. The second depends on changes in the number or type of circulating leucocytes, and towards this method attention has been solely directed in the investigation here described.

Blood counts have been employed in the diagnosis of whooping-cough for over a quarter of a century. Ever since Frölich¹ made the fundamental observation in 1897, leucocytosis has been regarded as characteristic of the disease. Extreme figures have been recorded in pertussis pneumonia. Mitchell and Friedman² reported a case where 233,600 leucocytes were present and clinical evidence did not suggest leukemia. Figures of this magnitude are never reached in uncomplicated cases; indeed a true evaluation of the degree of leucocytosis can only be obtained when the figures are compared with the normal blood counts of childhood. It is occasionally difficult, from the scrutiny of reported results, to decide whether such a comparison was made.

Besides an absolute increase in the number of leucocytes, a relative increase in lymphocytes has long been recognised. As early as 1906 Churchill³ found that lymphocytosis was present in 85 per cent. of recorded cases. This change, he thought, was commonest in the early or catarrhal stage of the disease. More recently Sauer and Hambrecht,⁴ whilst confirming the general presence of leucocytosis and lymphocytosis in whooping-cough, found that the change was greatest at the height of the paroxysmal stage; at the beginning and end of the illness there was often leucopenia. They also noted a terminal decrease in the lymphocyte count.

The present investigation describes the blood count findings in 65 cases of whooping-cough. Most of these were in the late paroxysmal or early whooping stage of the disease and ages ranged from 3 months to 9 years. A division into age-groups has been made for convenience of comparison with Still's table of normal blood counts in childhood (Table I.).

TABLE I

Normal Blood Counts in Childhood (Still)*

	Birth.	Seven days old.	Six mths.	Two years.	Five years.	Ten years.

Mil.=millions.

*Still, G. F.: *Common Disorders and Diseases of Childhood*, London, 1927, p. 699.

Blood counts, which consisted of a total and differential leucocyte count, were performed at two stages in the disease—on admission and in early convalescence. The figures obtained were then compared with Still's table and the results expressed as plus or minus normal for the particular age-group. In an attempt to obtain uniformity of results, all the examinations were done by one of us (M. F. C.).

In order to classify the findings a salient abnormality, the increase in percentage of lymphocytes, has been used as the best criterion of variation. Four groups were obtained as follows:—

Group 1	Increase in percentage of lymphocytes.	{ 25 % or more 10-25 % 2-10 %
" 2		
" 3		
" 4.	No significant increase.	

RESULTS OF INVESTIGATION

An absolute increase in the number of leucocytes was present in every case; increases amounting to over 30,000 were occasionally obtained. On an average, each case was shown to have 10,064 leucocytes more than was normal for the age. It should be emphasised that we were dealing, almost exclusively, with uncomplicated cases of whooping-cough in the late paroxysmal or early whooping stage.

Lymphocytosis was less constant. The results in the various age-groups are given in Table II. It will be seen that lymphocytosis characterised some 77 per cent. of cases, and in 35 per cent. this change was marked. On the other hand, as many as 23 per

cent. showed no increase at all. A second point is worthy of attention. In the age-group under six months only 17 per cent. of children showed a marked lymphocyte increase and no less than 33 per cent. showed no increase at all. No other significant difference between the various age-groups was detected.

TABLE II

Percentage Distribution of Children According to Lymphocyte Increase in Various Age-groups

Age-group (years).	No. of cases.	25% or more.	10-25%	2-10%	No significant increase.
0-1 ..	6	17	50	0	33

2-5 ..	30	37	33	6	23
5-10 ..	8	37	25	0	38
—	65	36	38	3	23

Leucocyte Counts in Early Convalescence.—The next part of the investigation was an attempt to obtain some information as to the time at which blood counts returned to normal. For this purpose in 36 patients, who had showed abnormalities in the early count, the examination was repeated fourteen days later. It was revealed in consequence that in each case, by the fourteenth day of the whooping stage, the leucocyte count had returned to physiological limits. This was equally true, whether the initial lymphocytosis had been marked, moderate, or mild.

DISCUSSION

Certain qualifications must be made to the wholesale acceptance of blood counts in the diagnosis of whooping-cough. Although a general leucocytosis appears to be constant, this is not in itself of great value, since almost every respiratory infection of childhood is accompanied by an increase in circulating leucocytes. A combination of cough, leucocytosis, and lymphocytosis is strongly suggestive, but a relative lymphocytosis is shown to be absent in 23 per cent. of cases—a considerable margin of error for a laboratory aid to diagnosis. This margin, unfortunately, appears to be accentuated in the very young—just when difficulties in diagnosis are most likely to arise. In spite of these objections a blood count must remain a valuable accessory method of diagnosis in whooping-cough. Characteristic leucocyte changes are present in a high proportion of cases and are at their maximum before the whoop appears.

SUMMARY

(1) In whooping-cough leucocytosis is constantly present. Lymphocytosis is less constant and this is particularly so in children under six months of age. (2) The blood changes are at a maximum early in the disease and rapidly subside after the whoop is established.

We desire to acknowledge our indebtedness to Dr. E. H. R. Harries, medical superintendent of the North-Eastern Hospital, for his coöperation and for his permission to publish this paper.

RESECTION FOR CARCINOMA OF THE SIGMOID AND SIGMOID RECTUM

By D. PHILIP MACGUIRE, M.D., F.A.C.S.

ASSISTANT CLINICAL PROFESSOR OF SURGERY OF THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, COLUMBIA UNIVERSITY

For knowledge of the technique and results of resection and permanent colostomy in cases of cancer of the sigmoid and sigmoid rectal areas, we are indebted to W. E. Miles,¹ William J. Mayo,² Daniel F. Jones,³ Robert C. Coffey,⁴ Frank H. Lahey,⁵ and Fred Rankin.⁶ For many years we all have hoped to have established an aseptic technique for resection of the sigmoid and sigmoidal rectal area in cases where the size of the tumour makes it unsuitable for removal and anastomosis either by the Paul-Mikulicz technique, the Morrison-Balfour technique, or anastomosis with suture. The procedures that the above-named authors have advised consist in a two-stage operation

FIG. 1.—Extramural lymphatic structures of rectum and sigmoid (after Miles).

for the radical removal of the tumour and a permanent colostomy. In all these operations the bowel is double-clamped intraperitoneally and the proximal end brought out for the permanent colostomy opening. Most of them, except Lahey, have advised burying the distal segment under the floor of the pelvic peritoneum and its removal at a later stage.

I disagree entirely with this technique, because the simple clamping of the bowel damages the intestinal wall so severely that hordes of bacteria, both microscopic and ultramicroscopic, are spilled into the peritoneal cavity. For years, we have all recognised that the greatest danger in these operations is peritonitis—whether due to direct implantation resulting from severing the colon, to infection in the neighbouring mesentery or to tension causing a leakage of bacterial contents into the peritoneal cavity. In

the procedures described below, I feel that we have arrived at the most aseptic method of removal so far described.

In the first stages the cæcum is withdrawn through a McBurney incision and anchored there for 48 hours. This can be done by applying a clamp to the mesentery of the appendix or suturing the parietal peritoneum to the mesentery, care being taken that at no time is a needle inserted in the colon proper for fear of infection. A Paul's tube is then introduced after 48 hours and a suction apparatus connected of the Wagensteen type. Because of the loss of fluids, we have to give

5 per cent. glucose and normal saline solution by intravenous injection and also by clysis, up to 4000 to 5000 c.cm. during the first few days. Blood transfusions are ordered as the need arises. When the condition of the patient warrants it, he is sent home for a two months' rest, before the radical abdomino-perineal operation is performed.

Upon return to hospital, a complete check-up is made. The administrations of transfusions, glucose, and saline solution, and also the application of an indwelling catheter are ordered. A median or left incision is now made and the mesentery of the left colon is resected from a point above the growth down through the peritoneal reflection, the gland-bearing area being excised (Figs. 1-3).^{*} The abdomen is

FIG. 2.—Sagittal section showing peritoneal reflection.

FIG. 3.—Resection of sigmoid and sigmoid rectal by the abdominal route.

areas is painted with iodine, and gauze soaked in iodine is introduced into the rectum. The aperture is then closed with a continuous suture so that more iodoform gauze can be applied to the lower segment and this, in turn, is enveloped in a sterile rubber glove. The perineal incision is made preferably with a cautery and continued until sufficient rectum extrudes, as shown in Fig. 4, in order that a second sterile glove can completely envelope the lower bowel segment. After dissection up to the peritoneal reflection, the abdomen is re-entered, the peritoneal reflection dissected, and the entire loop drawn upward into the abdominal cavity. It is then carried through a separate incision made through the left rectus muscle for the purpose of fashioning a single-barrel colostomy. The peritoneal reflection is closed; the cut edges of the sigmoid mesentery are sutured to the left parietal peritoneum to prevent herniation,

FIG. 4.—Perineal dissection of rectum.

and the incision in the abdomen is also closed in the usual manner. The extraneous gut is double-clamped a few inches from the colostomy opening and severed with a cautery. In the operative procedures that I have described, not once have we used clamps across the lumen of the bowel nor have we severed the colon by cautery intraperitoneally; nor do we permit any suturing of the colon wall to the parietal wall of the peritoneum.

The so-called aseptic procedures utilising various forms of clamps are, in my opinion, misnomers, as the traumatism applied to the bowel by these clamps is sufficient to cause much of the peritonitis in cases of malignant disease of the colon.

The post-operative care of these patients is very important. They are made comfortable by the use of morphia, and 4500 c.cm. of glucose and saline solution is given by hypodermic clysis or intravenously for the first few days. In all my cases I have used an indwelling catheter and have given irrigations of boric acid for at least one week after operation. Parotitis is a complication which causes some anxiety, but in recent years the early use of radium has had a favourable influence.⁷ Repeated blood transfusions are given as indicated by the condition of the patient.

CLINICAL AND LABORATORY NOTES

EXOPHTHALMOS IN AN AGED SPINSTER

By Sir THOMAS OLIVER, M.D. Glasg., F.R.C.P. Lond.

EMERITUS PROFESSOR OF MEDICINE, UNIVERSITY OF DURHAM
COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE

WE are familiar with exophthalmos accompanied by varying degrees of enlargement of the thyroid gland during the early decades of adult female life, but I have recently had under observation a case of exophthalmos with atrophied thyroid in a spinster 84 years of age. The vagaries of the thyroid gland, with or without accompanying exophthalmos, form an interesting study. In simple goitre the thyroid may reach a considerable size, encircling the front of the neck and, apart from pressure, may cause little inconvenience, whereas a comparatively slightly enlarged thyroid may be attended by the unpleasant and distressing symptoms observed in Graves's disease. Occasionally the latter may run a rapidly fatal course. Some years ago I was called to a neighbouring town to see a young woman, 20 years of age or thereabouts, who was the subject of one of the severest and most distressing forms of acute Graves's disease. A healthy woman, she was engaged to be married, but the engagement had been suddenly broken. After two sleepless nights the patient developed exophthalmos with distinct enlargement of the thyroid gland, had a rapid pulse which could hardly be counted, accompanied by audible and visible beating of the heart. Treatment failed to slow the action of the heart or to give the slightest relief. Patient died on the fifth day of her illness.

While exophthalmos and thyroid implications are frequently associated in Graves's disease, the extent of the protrusion of the eyeballs bears no relation to the size of the goitre. Small and medium-sized soft goitres are more frequently accompanied by exophthalmos than are the larger, and in them a marked thrill may be felt and a bruit heard on auscultation.

It was towards the close of last year, when the elderly patient above mentioned was 83 years of age, that exophthalmos developed and rather rapidly increased. For over 40 years she had consulted me at irregular intervals for heart trouble, mitral regurgitation. During the last decade or a little more, she became the victim of widely distributed rheumatoid arthritis affecting the fingers and toes, but apart from occasional indisposition her health remained on the whole good, until three years ago when she began to lose flesh and had pains in the abdomen. Two fairly large irregular masses could be felt, one in each side of the abdomen, and which at times were painful on pressure. The glands in the groins became enlarged and the superficial veins in the lower left abdominal wall became dilated to the size of a quill pen. Under the administration of colloidal copper the hard masses referred to became reduced in size to almost vanishing point. The superficial veins in the abdominal wall also became markedly smaller and with the subsidences her general health improved.

In the early months of this year it was noticed that the eyeballs had become protuberant and staring, a circum-

stance which gave anxiety to her friends. The exophthalmos progressed so that the eyelids could not be closed entirely. The globes were at times painful, and from the orbits at intervals there gushed streams of clear water. The pupils, then and all through her illness, remained normal; the pulse ran between 70 and 82. The condition of the heart remained little altered: occasionally there was slight irregularity which improved with cardiac tonics. Emaciation progressed with the result that no thyroid gland could be felt; the rings of the trachea could be seen and traced all the way down. There was neither palpitation, undue restlessness, nor vomiting; the extremities were always cold, and the urine was free from albumin, sugar, and aceto-acetic acid. There were no signs of incipient myxœdema; her brain was active and her mind alert. In the course of the illness there was for a few days double vision, and in March the urine for the first time contained albumin.

A few weeks later as there was a return of the diplopia Mr. J. S. Arkle, an eye specialist, saw patient with me. He attributed the diplopia to unequal strain upon the ocular muscles. He found the discs normal and that there was no congestion of the retinal vessels. No explanation could be given of the exophthalmos or of the gushes of liquid which were still considerable. Drops of purified petroleum were ordered to be inserted into the eyes, and the patient to wear and to sleep in special glass protectors. In May the gushing of liquid from the eyes ceased, the urine contained a larger trace of albumin, and œdema of the feet developed, but in a few days the œdema disappeared under the influence of digitalis, juniper, and squill.

As the illness progressed patient lost flesh rapidly; she became restless, sleepless, and excitable; she became the subject of delusions, saw all manner of living objects in her room, and talked audibly to herself. Bromide and codein gave relief, but it was not until two or three half-grain tablets of calomel had been taken that her mind became clear. I regarded the symptoms as toxæmic. As the end drew near, Cheyne-Stokes respiration became marked, the heart's beat irregular, and the pulse, which had fallen to 56, rose to 146, the respirations reached 56, and the temperature 102° F. Patient died in coma.

The marked and rapidly produced protrusion of the eyeballs in my aged patient never seemed to me to be explained by thyroid influences, for the gland was atrophied, nor directly through the sympathetic nerves. Its rapid development, pain in the eyeballs, and the gushing of clear water from them in such quantities as to saturate in a very short time two or three handkerchiefs suggested some local condition behind the eyeball itself. Prof. R. B. Green, my colleague in the College of Medicine, with whom I discussed the subject, also thought that the cause, secondary if not primary, lay within the orbital cavity. He drew my attention to an article on Periorbita in Prof. S. E. Whitnall's "Anatomy of the Human Orbit" (1932), in which is described a mass of smooth muscle tissue lying in the inferior orbital fissure, and incorporated with the periorbita, which like periosteum is a sheet of fibrous tissue lining the interior of the orbit and supporting the nutrient arteries of the bone. This muscle, known as the orbital, has been described by H. Müller and is not to be confused with the involuntary palpebral muscle which also bears his name. He calls it the "peri-orbital." It fills the inferior orbital fissure, and in proceeding forward it spreads out in a fan-shaped manner over the orbital floor. Whitnall, from whose interesting and suggestive article I have borrowed freely, ascribes to it a twofold interest. The muscle is found in all mammals except those of the aquatic group. O. Burkard, who has studied it from the point of view of comparative anatomy, holds that it is an important accessory to the lacrimal apparatus. Its function however in this respect is not clear, but in

certain animals, in addition to keeping the globe tense, it can protrude the eyeball, as Müller found on irritating the cervical sympathetic nerves.

The second point of interest is a pathological one and concerns the exophthalmos of Graves's disease. It might seem impossible for contraction of the periorbital muscle, which is a vestigial structure, to alter the position of the eyeball by compressing the mobile orbital fat and obstructing the venous circulation, but H. Frund, who has carefully studied the muscle in the new-born, considers the explanation is sufficient. If we admit with him that the periorbital muscle might cause protrusion of the eyeballs, its contractions would primarily have to overcome the pull normally exercised by the recti muscles unless these had become functionally weakened and inefficient. Despite the careful investigations which have been made into the pathology of exophthalmos, there would still appear to be a call for further research into its primary cause or causes.

DUODENOCOLIC FISTULA

By A. H. SALEH, M.B. Edin.

ASSISTANT MEDICAL OFFICER, MUNICIPAL GENERAL HOSPITAL, BURNLEY

THE rarity of this condition and the recent publication of a similar case¹ prompt me to report the following:

A man, aged 69, was admitted to the Municipal General Hospital on Sept. 28th, 1935, with a history of intractable diarrhoea for three months, preceded by severe constipation. During the last few weeks vomiting had set in. The vomit at first was mostly clear fluid, but later became faecal and very offensive. He had lost a lot of weight and complained of pain across the chest.

¹ Mindline, J., and Rosenheim, M. L.: Duodenocolic Fistula Simulating Idiopathic Steatorrhoea, *THE LANCET*, Oct. 5th, 1935, p. 764.

On examination he looked grey, dehydrated, and wasted. His temperature was subnormal, the pulse- and respiration-rates rapid. Flatulence was marked. There was tenderness all over the abdomen and rigidity over the upper part of the right rectus. No mass was felt. The tongue was thickly "coated" and the breath foul. The heart showed dilatation, and the lungs crepitations at their bases. The pupils were slightly dilated and the knee-jerks sluggish. The stools were frequent and very loose. He went downhill quickly and died 36 hours after admission. While in hospital he had no diarrhoea at all. At autopsy, which I performed a few hours afterwards, the heart was found to be flabby and enlarged, and the lungs congested at the bases. The liver had a nutmeg appearance; the gall-bladder was full and tense and had a puckered cicatrix posteriorly; there were no gall-stones; the pancreas was hard, the prostate enlarged, and the peritoneal cavity clean; the intestines were deflated except the caecum which was ballooned. The hepatic flexure, duodenum, and head of pancreas were matted together and very friable, particularly between the duodenum and the flexure, where a perforation was noticed (probably artificially produced during the handling of the parts). On section a fungating mass was found in the hepatic flexure, ulcerating through into the duodenum and forming a fistula about half a centimetre in diameter. Microscopically the growth was found to be a diffuse adenocarcinoma invading the intestine deeply. A section from the middle of the body of the pancreas showed tissues of the character of intestinal mucosa. No other secondaries were found.

This, then, was a case of duodenocolic fistula due to an adenocarcinoma of the hepatic flexure. A curious point about it was that the patient himself informed me that he had "cancer of the bowel," but emphatically denied being told so by anybody. The stools, although frequent and very loose, were not steatorrhœic, as seen by the naked eye. The condition was not recognised before death, because full investigations were not carried out in the short time during which the patient was seen alive.

I am indebted to Dr. D. C. Lamont, medical superintendent of the hospital, for permission to publish this case.

MEDICAL SOCIETIES

JOINT CONFERENCE ON THE WELFARE OF CRIPPLES AND INVALID CHILDREN

Mr. H. S. SOUTTAR presided over a meeting held last week at the Drapers' Hall, Throgmorton-street, during the joint conference on the welfare of cripples and invalid children.¹ The subject of discussion was

The After-effects of Accidents

Speaking of fractures due to accidents, he said that one of the great difficulties was not repairing the fracture so much as repairing the men and getting them back to useful life. If a man's compensation provided him with a satisfactory income his enthusiasm for work was not great. That did not apply to the child, but even with the child the problem of restoring full function was of the greatest importance. These issues were the more important because the number of accidents was increasing.

Lieut.-Colonel J. A. PICKARD (National Safety First Association) said that accidents of all kinds killed 3000 children annually, half of that number in road accidents, while for every fatal road accident there

were 30 non-fatal ones. More foresight and care on the part of drivers as well as the cultivation of road sense in the child without any great curbing of his natural spirit of adventure, was essential. Of 500 road fatalities to children 386 occurred to children on foot, 103 to those cycling, and 11 to passengers. He advocated a much larger use being made of models and films to teach road dangers to children.

Dr. H. C. CAMERON (Children's clinic, Guy's Hospital) spoke of the effects of accidents on the nervous system. Cerebral damage or compression, or contusion or concussion might occur, and occasionally persistent atrophy of brain or a traumatic dementia. There might result extreme excitability and restlessness, with disturbances of conduct; while injury to the head might be followed by convulsions, and lack of moral control, possibly with epilepsy. Functional disturbances were a very prominent sequel of accidents, because of their terrifying effect, even if the child had merely seen the accident without being involved in it; the attitude of the accompanying adult could influence the child's disturbance, for good or ill. Often a state of unrest was caught from the grown-up person, and might be manifest as mutism or hysterical convulsions.

Mr. S. A. MALEIN, F.R.C.S., (Harlow Wood Orthopaedic Hospital), spoke of the need for coöperation

¹ Under the auspices of the Invalid Children's Aid Association and the Central Council for the Care of Cripples.

between cottage, general, and orthopædic hospitals in this work. The medical profession had long been dissatisfied with some of the results of the treatment of accident cases, but there was now a steady improvement. The British Medical Association Committee on Fractures had attributed the bad results not so much to lack of professional skill as to lack of organisation or faulty organisation. Cottage hospitals were mostly staffed by men with busy private practices, who had neither time nor opportunity to work a fracture service. Orthopædic hospitals were in a specially favourable position to treat fractures. In any scheme formulated municipal hospitals should be included. The best link would probably be one surgeon in charge of the fracture service on the staff of all the associated hospitals, appointing such assistants as were needed.

Dr. ELIZABETH CASSON (Dorset House School of Occupation Therapy) spoke on occupational therapy as applied to recovery of children from accidents. Occupational therapy included any activity, mental or physical, designed to contribute to and hasten recovery from disease or injury. Concentration by the patient on the cure of his condition sometimes retarded it; occupation often resulted in unconscious movement of the injured member. Every muscle action was the result of a stimulus, and a desideratum of occupational therapy was to arouse specific emotions which resulted in the desire to use such muscles as would aid restoration of health; then came the desire to achieve.

Mr. CECIL KNY (late adviser to the Government on industrial development) pleaded for a widening of the existing conception of training cripples. A trainee had to master many functional operations before becoming a skilled craftsman. The radio industry was one well suited to many cripples. He favoured the establishment of an industrial training workshop for cripples, to be run on a business basis; it should have a psycho-technical department for the vocational selection.

Dr. G. MACFEAT (Douglas, Lanark) spoke of a plan of treating cases of accident in the coal industry, based on the co-operation of doctors, employers, and employees, which had received the unanimous approval of the Lanarkshire Orthopædic Association. Efforts were also made to procure suitable light work for those unable to resume their ordinary work.

Dr. J. GREENWOOD WILSON (Cardiff) said that a municipal fracture service would be opened at Cardiff in a few days, with 6 male and 6 female beds, X-ray installation, and a staff consisting of orthopædic surgeon, sister, and nurses. Cases needing long treatment would be transferred to another hospital under the same surgeon.

Dr. C. O. STALLYBRASS (Liverpool) said that in Liverpool street accident cases must be taken to the nearest hospital, whether municipal or voluntary, where the orthopædic surgeon would see them through to the end of their treatment.

Mr. D. R. WILSON (H.M. chief inspector of factories), who presided when the discussion was resumed after lunch, said that last year there were 136,858 accidents in factories, 785 being fatal. The total number of accidents including those on roads and railways and in mines probably reached nearly half a million, and the fatalities 9000 to 10,000. Among young workers the accident rate was persistently higher than among older ones. He had often wondered what ultimately happened to the man disabled in industry, often through no fault of his own.

Mr. J. L. SMYTH (Social Insurance department,

Trades Union Congress) said that for more than a century trade unions had been protecting workers against the hazards of industrial life. After an industry had finished with him the crippled worker was largely left to his union. In this country there was no properly organised accident prevention service, though the great bulk of the accidents were preventable. Those returning to work after long periods of unemployment were very prone to accidents. The injured worker who did not belong to a trade union was often tricked into accepting a quite inadequate sum as total compensation. Home Office statistics showed, in ten years, that the average profit made by the insurance companies in cases of injury to workers was over 12 per cent., and the legal and medical charges 36 per cent., the amount actually paid in compensation being 54 per cent. The trade union movement had framed an improved Workmen's Compensation Bill, which ought to be warmly welcomed.

Mr. GUY DE G. WARREN (Midland Colliery Owners' Mutual Indemnity Company) said that colliery companies in the Midlands had banded themselves together to protect their common interests; among their objects were the promotion of measures to prevent accidents, ill-health, or sickness, and to minimise the consequences thereof. A workman immediately after an accident was anxious to be restored to his work as soon as possible; if, however, his period of incapacity was prolonged he tended to become content to remain on compensation. It should be an obligation on the employer to provide efficient treatment, with medical referees to decide in cases where treatment was refused.

Mr. H. SAMUELS (Industrial Welfare Society) said that the original object of the Workmen's Compensation Acts was to protect the workman against the risk of accident at his work; yet the figures of accidents in industry showed no signs of lessening. The insurance companies did not reduce premiums in favour of employers who took steps to prevent accidents. If a system of "merit rating" of workmen's compensation premiums could be introduced, each firm would have a direct financial incentive to adopt up-to-date methods of accident prevention. With regard to cure, the financial provision given by the Acts was likely to promote cure; yet it was inherent in the system that the injured workman should often have to struggle with the insurance companies. In certain cases the employer could compel the acceptance by the worker of a lump sum in compensation, and then the man's mind became fixed in anticipation of this sum, instead of on getting well. His society welcomed the official committee set up to inquire into the system of medical examination of injured workmen, but his society felt that a mere amendment of the law was not sufficient; there should be national rehabilitation centres for the treatment of industry's daily victims.

Mr. DONALD NORRIS, F.R.C.S. (Insurance Institute of London) said that every year 400,000 claims were made in respect of disability from industrial accidents and diseases, and the annual cost of these was about seven million pounds. About 4 per cent. of people working in factories and railways, 10 per cent. in docks, and 20 per cent. employed in mines were disabled annually. His suggestion was that the main reasons for the present high cost and excessive duration of disability were: (1) inadequate preventive measures, (2) inefficient treatment, (3) difficulties in placing the workers in industry, (4) litigation. His impression was that the treatment of other injuries was not as a rule much better than that of

fractures. A vast total disability could be obviated if trivial injuries were not allowed to become septic. Many thousands of injured workmen attended hospitals thrice a week for massage and electrical treatment which were not effective.

Mr. GEOFFREY PETO, M.P. (Central Council for the Care of Cripples), wanted to see a Workmen's Restoration Act.

Mrs. Councillor DEACON (North Staffordshire), who said she had for long been living on 29s. 6d. a week, protested against the forcing of injured workmen to accept ridiculous sums as compensation, and against the delay before any payments were commenced.

Dr. H. E. MOORE (Crewe) agreed there was often a long delay between the occurrence of the incapacity and the possession of the papers entitling to payment. He joined his plea for the establishment of rehabilitation centres.

Dr. D. MORGAN (Trades Union Congress) thought there should be national rehabilitation centres in which the worker could have confidence. He denied any desire on the part of men to prolong the period of payment of compensation.

LIVERPOOL MEDICAL INSTITUTION

At a meeting of this institution, held on Oct. 24th, with Dr. C. O. STALLYBRASS, the president, in the chair, a paper on

Ephedrine in the Treatment of Enuresis

was read by Dr. R. W. BROOKFIELD. Ephedrine, he said, was generally known to be useful in the treatment of asthma and other allergic states but its value in the treatment of enuresis was insufficiently appreciated. The bladder, like other organs, had a dual innervation. Its nerve-supply was derived through the sympathetic and sacral autonomic (parasympathetic) systems. Relaxation of the internal sphincter and evacuation were favoured by parasympathetic and inhibited by sympathetic impulses. There was reason to suppose therefore that ephedrine, as a sympathetic stimulant, would have a favourable effect in cases of enuresis by contracting the internal sphincter and relaxing the bladder wall. This expectation was fulfilled. His custom had been to give an initial dose of ephedrine hydrochloride half a grain at bedtime, and increase it by gr. $\frac{1}{4}$ every 4-7 days until the enuresis was controlled. Some patients showed a remarkable tolerance to ephedrine; as much as grs. 4 at a dose had been given without any unpleasant results. In many children, on the other hand, side-effects were apt to be troublesome; but these could usually be counteracted. Wakefulness and restlessness responded well to phenobarbitone gr. $\frac{1}{4}$ given with the ephedrine. Vomiting, which occurred sometimes, ceased on reducing the dose. The results achieved warranted the conclusion that ephedrine is the most useful drug at present available for the treatment of enuresis.

Dr. NORMAN CAPON said he had had some good results with ephedrine, and that it was a useful adjunct to the more fundamental treatment of this state, in which both physiology and psychology are disordered.—Dr. P. F. TIXNE condemned disciplinary measures which penalised a child for a condition over which it had no control. Often enuresis was entirely due to the irritation of threadworms in the lower bowel, and cleared up on their removal.—Dr. J. BERKSON remarked on the advantages of ephedrine

over large doses of belladonna, from the standpoint of the general practitioner.

Treatment of Infected Bones and Joints

Mr. R. WATSON JONES, in a paper on modern methods of treatment of bone and joint infections (illustrated by cinematograph), said that so far as wounds were concerned the best results would be got by avoiding the infection. The first requirement, therefore, was immediate excision of possibly infected wounds, hæmostasis, and primary suture with adequate immobilisation. When infection was already established, drainage of the bone or joint was imperative, but the question of after-treatment still remained. Whatever technique was adopted it must be equally easy to control the infection and to immobilise the limb. The incidence of pathological dislocation, of pathological fracture, and of postural deformity was far too high, and these complications meant that surgeons, in their anxiety to control the infection, had neglected to control the position of the limb. The Winnett Orr "no-dressings vaseline gauze plaster method" overcame these difficulties, and was especially valuable in the infected compound fracture. Although infection was responsible for delayed union, it was rarely responsible for non-union, and the frequency of non-union was attributable to the inadequacy of immobilisation which had hitherto been permitted. If the fracture was perfectly immobilised throughout the period of infection, and for several months afterwards, bony union was usually secured. The method was of particular value when extensive granulating wounds extended across joints as in the degloved hand, the degloved foot, after severe burns, or in cases of extensive pressure sores. Skin grafts could be employed beneath the plaster. Deformity was prevented, and because fibrosis of the tissues was minimised, the joints often retained their mobility.

Dr. D. WAINWRIGHT said he did not share Mr. Watson Jones's enthusiasm for the use of plaster in the immobilisation of acute hematogenous infections of bones and joints. He believed that the principles of the Winnett Orr treatment of these conditions could be observed by the use of other methods of immobilisation which had many distinct advantages. The initial treatment differed in no way from that employed by Mr. Watson Jones, but the method of immobilisation by external splinting—for example, the use of a Thomas splint in acute osteomyelitis of the lower end of the femur and upper end of the tibia, and the use of a Jones abduction frame in acute infections around the hip-joint—had the following advantages: (1) the adjacent joint is capable of inspection without removal of splint or dressings; (2) the surrounding skin can be inspected for local spread of infection and subcutaneous abscesses; (3) the external dressings containing the offensive dry pus can be removed without disturbing the granulating surface. Dr. Wainwright said he could personally vouch for the very real anxiety which might often attend these very acute inflammations when the whole limb is completely encased in plaster.

Mr. J. T. MORRISON remarked that the demonstration made the primary treatment of wounds appear altogether too simple. Excision of wounds was a difficult and tedious operation, particularly in cases of bone injury. Such accidents required treatment at least as urgently as abdominal emergencies, and it was strange that the insurance companies had not realised the immense savings they could effect by themselves providing expert hospital

service for the early treatment of such cases as was done in Vienna. During the first six hours operation could be freely undertaken. Thereafter the wound ceased to be merely a contaminated wound and became to an increasing extent an infected wound, with corresponding risk attached to any interference. Referring to the Winnett Orr treatment, Mr. Morrison said he could not see the necessity for complete enclosure of the limb in plaster. Could the surgeon not trust himself or his assistants to keep from interfering with the pack in the wound? There ought in every case to be a definite positive indication for changing any dressing. He agreed with Mr. Watson Jones about the relative unimportance of antiseptics and the great benefits secured by complete rest to an infected wound. He was much impressed with the possibilities revealed in the plaster treatment of patients with severe bedsores.

Mr. BRYAN MCFARLAND said that the best results of compound injuries described at the meeting had been obtained not by the treatment of Winnett Orr, who advocated leaving wounds open, but by primary excision and suture. The speaker had practised this before the Winnett Orr method was introduced, and he still believed that it was infinitely superior. In fact, although Winnett Orr had done one good thing in advocating covering up chronic wounds, whether from bone or more superficial injury, and so had brought people to realise that it was not necessary to keep wiping and dabbing, he thought he had done harm in confusing compound fractures, which were potentially sterile, with acute osteomyelitis, which was essentially infected. For osteomyelitis complete covering with plaster with no window was a bad procedure; for compound fractures it was better to perform primary excision and suture and encase in plaster. If the wound became septic it was much less than if it had been left open, and in 9 cases out of 10 there was primary union without sepsis.

Mr. E. N. WARBLE thought no one could take exception to Mr. Watson Jones's contention that early operative interference is the best treatment for wounds of bones and joints. The more one saw of this kind of case, the more care one took with the primary excision and suture and the better were the results. As for established infection, it seemed to him that the Winnett Orr method had done one great thing; it had relieved patients from a very painful daily dressing. The method was a sound one, but it had its limitations. The wound so treated must be wide and shallow.

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY

At the meeting of this section on Nov. 6th Mr. W. SAMPTON HANDLEY, the president, opened a discussion on

Paralytic Ileus in Acute Appendicitis

The condition, he said, was uncommon, but he had chosen to speak about it because he believed that these otherwise very fatal cases were amenable to timely and energetic treatment of a kind he had described in two Hunterian lectures. Jejunostomy, which seemed to find favour, he did not regard as a solution of the problem; nor did he agree that modern methods of medical treatment had abolished the necessity for surgery. In all the cases of paralytic ileus he had seen, medical measures had been

perseveringly tried, and he had been much impressed by the value of the indwelling stomach-tube; but one should beware of postponing operation until it was too late. In operating he did not use spinal anaesthesia, for he feared a dangerous fall in blood pressure.

Even after death "general peritonitis" was rarely found to have spread throughout the peritoneal cavity. One advantage of man's upright posture was this cavity drained to a low point. The dog, without this postural advantage, was killed by peritoneal infection in three days. In man, peritonitis began in the pelvis; even when the septic focus was high in the abdomen, it quickly drained into the pelvis, unless adhesions formed. The pelvis filled with pus from below upwards, and at a later stage hypogastric rigidity supervened. The jejunum, transverse colon, liver, and diaphragm remained uninfamed and unparalysed until the patient became moribund, and this fact was the key to successful treatment. Clinically, therefore, there were three stages of so-called general peritonitis: (1) pelvic peritonitis, (2) hypogastric peritonitis, and (3) the hopeless "text-book" stage. With the first of these gynaecologists were only too familiar: there was acute rectal and vaginal tenderness, but no hypogastric rigidity; there might be vomiting and right iliac rigidity; if the appendix was pelvic in situation it might be felt as a definite swelling. It was on the recognition of the second stage (hypogastric peritonitis), however, that the preservation of life depended. This stage might not last longer than 24 hours.

Intestinal paralysis might arise in the pelvic stage of an upward-spreading peritonitis, but the intestines above the pelvic brim, though distended, were not inflamed. Twenty-five years ago he had applied to this condition the term "ileus duplex" to indicate the presence of two obstructions. Of 3 cases he had treated by ileocecostomy and cecostomy, all recovered; whereas of 10 earlier cases treated by other methods, 7 died. Of those 10, 6 were treated by ileocecostomy alone, and 4 of the 6 died. Cecostomy should be regarded as a routine precaution, though it might not be essential to recovery in a particular case. The failure of ileocecostomy in paralytic ileus contrasted with its success in mechanical obstruction of the lower ileum; the speaker had performed the operation 8 times for mechanical obstruction, and had had 7 recoveries; for paralytic ileus he had done it 5 times, with 4 deaths. In some exceptional cases in which large intestine obstruction was partial or absent, enterostomy might succeed.

When peritonitis supervened in the hypogastric stage the operative problem became different. It was necessary to construct a short but complete alimentary canal above the level of the peritonitic flood. A distended coil of jejunum was anastomosed to the transverse colon, and the caecum was opened. Reflux then took place from the anastomosis along the transverse and ascending colon to the cecostomy. The effect of this on almost moribund patients was dramatic. He had done it five times, with four successes, the fifth patient having died a month later from pyaemia, which bore witness to the intensity of the sepsis. Enterostomy in these cases drained only the small intestine; the large intestine was forbidden by the ileocecal valve to empty itself into the small intestine, and paralysis of the pelvic colon usually prevented relief per anum. A large anastomosis was not necessary; the large intestine recovered rapidly, and the cecostomy wound usually closed spontaneously in a month or six weeks.

A late and unexpected sequel of lateral anastomosis between the small and the large intestine without resection or interruption of their continuity was the development of symptoms resembling those of pernicious anæmia; in his first case the interval was eight years. Physiologists had noted that in animals the operation might ultimately induce fatal anæmia, in a way not yet explained. The necessity of carrying out a secondary operation at a remote date in these cases might appear a serious drawback to the measures he was advocating, but surely it was not too high a price to pay for recovery from a condition which otherwise might prove fatal immediately?

The best results from jejunostomy were those recorded by Seton Pringle—namely, 7 recoveries out of 9 cases; but it seemed clear that he did the operation on a prophylactic basis, without waiting for signs of actual obstruction. This policy was defensible, but only a small proportion of cases with free pus in the pelvis proceeded to obstruction, and few surgeons cared to undertake enterostomy except for reasons which were really compelling. German experience of jejunostomy had been less favourable. Selling Brill, of Philadelphia, said it was proper to assume that if a case of peritonitis with signs of obstruction recovered without operation the peritoneal infection was mastered, the fibrinous exudate was absorbed, and the bowel resumed its normal activity. Recent experience at the Mayo Clinic seemed definitely unfavourable to enterostomy in acute obstruction; J. J. Morton, of that clinic, said it tided over the crisis until the real problem could be handled. In Mr. Sampson Handley's opinion enterostomy usually failed because it could drain and relieve only the small intestine; it was useless to deal with only one of two lethal conditions.

Ileosigmoidostomy seemed a rational procedure for cases in which peritonitis was confined to the pelvis, and where the pelvic ileum was paralysed and the pelvic colon merely paretic, but it did not make provision for the emptying of a paralysed large intestine. After one failure he had abandoned it.

Mr. PHILIP TURNER said he had been very unfavourably impressed by the results of surgery in paralytic ileus, though he had not tried the operation which Mr. Handley recommended. There was more than one kind of ileus, and often it was hard to say what kind a patient had. First, there was a preoperative ileus; secondly, an ileus duplex; and thirdly, post-operative ileus. For this last kind he had done a fair number of enterostomies, but almost all the patients had died, and he had accordingly ceased to use the method. The successful cases were those in which the pus was at a low level and there were a few distended coils of intestine low down. For such he used a large trocar and cannula, through which much gas and faecal matter could come out. He did not leave a tube in. He had come round to a belief in serum in these cases; and he also thought an enema of treacle (not golden syrup, but molasses) was very useful.

Prof. G. GREY TURNER said the mechanical factor in these cases was not always given due attention, and referred to the insistence by the late Mr. Barker, of University College, on the extreme value of excluding a large portion of involved intestine. Many of the cases referred to by Mr. Handley were of a type in which interference was practised too soon and too often. It was hard to know when it was right to operate on these patients who were desperately ill, or when to leave them alone in the hope of a localised abscess forming. As the condition was rare the

measures now advocated were not likely to have much effect on the general appendicitis mortality. Some cases had developed faecal fistula, and immediately afterwards began to get well. He thought the time had arrived for a reconsideration of the whole question of appendicitis, the mortality from which was still far too high. When the trouble was in the lower pelvis, he thought it might be wise to operate in stages, dealing with complications as they arose. In this way the acute stage was survived, and complete removal of the appendix could be done in favourable circumstances. He would like to see a campaign in favour of the earlier and more rational treatment of acute appendicitis.

Mr. VICTOR BONNEY said that when, in 1910, he advised jejunostomy it was for a condition very different from the paralytic ileus which sometimes followed appendicitis. He recommended it for functional intestinal obstruction coming on after any abdominal operation and not dependent on inflammation of the peritoneum. The same functional obstruction occurred after prostatectomy and after peritoneal nephrectomy, and he had seen it twice in pregnancy. It was well recognised as a terminal event in pneumonia, and in his Bradshaw lecture last year he had expressed the view that the condition of the intestine depended on some agent formed in tissues damaged by operation or disease. In that class of case the obstruction started high. Perhaps some such term as "functional peritonitic ileus" would prevent confusion between the two conditions.

Mr. SEYMOUR BARLING (Birmingham) said that in recent years he had drifted towards medical rather than surgical treatment for the cases under discussion. He carried out Mr. Handley's operation soon after the end of the war, and occasionally he had done jejunostomy for them; but on the whole he was hesitating more and more to interfere surgically when medical measures had failed and the patient was in a desperate state. He could not bring himself to carry out such severe operations as anastomosis, though occasionally he had done jejunostomy with some success. His impression was that peritonitis tended to be more erratic in its manifestations than the President had suggested. The danger of trouble arising when the appendix was pointing in the direction of 2 o'clock had been stressed by Mr. Lloyd, after long experience; in these cases there was usually very widespread infection. Ileus was apt to be progressive; distension led to kinking and interference with the circulation, and this to an alteration in the diffusion of gases into the blood. He had always thought that jejunostomy did something to break the vicious circle set up. He believed that many of these patients died of streptococcal septicæmia rather than obstruction. A really irritating brine enema he had found valuable; he had not tried a treacle enema.

Mr. TURNER WARWICK said he had been much impressed by the success of Mr. Handley's combination of ileocolostomy and cæcostomy.

Mr. W. STEWART DICKIE thought that the type of case described by Mr. Handley was not often seen. In such there was no doubt about the obstruction of the ileum, but in reality there was very definite obstruction in the colon. He had been pleased to hear emphasis laid on washing out the stomach. He had no liking for the indwelling tube; a small tube was better than a Crile tube. He had found that a patient who had a rigor usually went steadily downhill.

Mr. W. E. TANNER said that two years ago he had the opportunity of undoing a lateral anastomosis

between the jejunum and the middle transverse colon for ileus. When he opened the abdomen he wondered what the operation had been done for, since the only remnant of a pelvic peritonitis was a single adhesion, half an inch long, joining the intestine to the bottom of the pelvis. That patient had severe anæmia. In one case he had joined the jejunum to the ascending colon for paralytic ileus, and with success; but he passed a long tube through the anastomosis into the small intestine, and it closed in less than a fortnight.

Mr. A. DICKSON-WRIGHT spoke favourably of spinal anæsthesia for vaginal hysterectomy and peritonitis with obstruction. When there were signs that a patient was going wrong he passed a very long stomach-tube, so that its end hung in a bowl, and in that way siphonage took the place of elaborate suction apparatus. He gave the patient two days' rest, with a hot pad and morphia; if that failed he stimulated. In his hands enterostomy had not been a success. Spinal anæsthesia would induce an intestine to contract if it retained the power to do so; but it must be a high spinal, 0.8 c.cm. of 20 per cent. ephedrine being given previously. He thought there was no danger of a fall in blood pressure.

Mr. CHARLES DONALD suggested that the severest form of ileus was not associated with much pus; rather it was accompanied by a focal fibrinous exudate round the terminal part of the ileum.

SECTION OF THERAPEUTICS AND PHARMACOLOGY

A MEETING of this section was held on Nov. 12th, with Dr. DOROTHY HARE, the president, in the chair, when Prof. E. C. DODDS opened a discussion on the pharmacological action and clinical use of

Drugs with a Camphor- and Coramine-like Action

Prof. Dodds said that from the general pharmacological standpoint camphor, its related compound the sodium salt of camphosulphonic acid, and a laevo-rotatory compound which was also known, might be regarded as equally active. One of the main difficulties in studying camphor was its marked insolubility. It might be administered in oily solution and in this form was said to be absorbed from the alimentary tract and, of course, following subcutaneous injection. In the body it was oxidised to an alcohol called camphorol, excreted in conjunction with glycuronic acid; camphorol was inactive and pharmacologically, therefore, the action of camphor could at the best of times only be very brief. Its main action, on the circulatory system, was inconstant, and the same applied to its action on respiration. It was no exaggeration to say that an experienced pharmacologist would find it impossible to support the claims of clinicians that camphor is a powerful stimulant of the circulation and respiration. Its use in collapsed and moribund patients could only be regarded as a placebo. The soluble sodium salt of camphosulphonic acid was no more active.

The compounds of pyridine included the group of circulatory stimulants familiar under the names of nicotine, lobeline and sparteine. One other compound—the β -carboxylic acid diethylamide of pyridine—was more familiar as coramine. All these four compounds had the power of stimulating respiration; from the quantitative point of view, coramine was much the most powerful of them.

The injection of such small quantities as 50 mg. into a 2 kg. rabbit produced a very marked change in respiration. The problem arose whether these compounds acted by direct central stimulation or peripherally through the sino-aortic nerve-endings. Nicotine and lobeline in small quantities appeared to act peripherally, but larger doses act by direct stimulation of the respiratory centre. The action of coramine appeared to be merely central. Unlike camphor, coramine exhibited a very powerful pharmacological effect in small doses by mouth or intravenously, a decided stimulation of the depth and frequency of respiration together with an increase in the force of cardiac contraction, shown by an increase in blood pressure. If given in large doses to animals definite evidence of cerebral stimulation could be seen. Since the action on the heart was entirely through the central nervous system, it was unfair to compare this drug with digitalis. There was also good evidence that coramine constricts the peripheral blood-vessels. Clinically the drug had been used extensively in all conditions associated with shock and depressed circulatory and respiratory states. These included diabetic coma, post-anæsthetic collapse, and pneumonia in certain stages.

Prof. Dodds related his own experience of the drug's action in diabetic coma, when the blood pressure was usually low, and the patient suffered from a very depressed circulation, the force of cardiac contraction being poor. In the terminal stages the pulse was imperceptible at the wrist and the colour of the patient very bad. An intravenous injection of large doses of coramine produced an immediate change; the pulse becomes perceptible and the colour returned. If the diabetic condition could be got in hand, such a patient would surely have a very much better chance than one whose circulation has not been stimulated. Other drugs, such as adrenalin and ephedrine, appear to have little or no effect on this condition.

Prof. Dodds sought the opinion of experienced clinicians on the value of camphor injections and on the question whether the stimulation of circulation by means of drugs of this class was a potent factor in cases of the types mentioned.

Dr. R. A. YOUNG said that it was always a joy when a drug, which had been used empirically and believed in, was established by scientific authority. As to camphor, once physicians had been told that this drug was useless, but many had been glad to use it in cases of pneumonia and felt that it did good. Another group of drugs—of which coramine was a notable example—had established itself clinically; it was gratifying to hear that the empirical experience had a scientific basis. He had used these drugs for many years—at first subcutaneously and intramuscularly, and recently by the intravenous route—and had seen very dramatic results. He believed the effect to be continued and valuable, especially in pneumonia. Repeated use had the disadvantage that patients might become intolerant to the needle and develop areas of cutaneous infiltration, redness, and pain.

Sir WALTER LANGDON-BROWN said that in the days of camphor administration he had thought that the drug just swayed the balance in some cases. He was rather surprised to hear that coramine was a cardiac stimulant, as he thought Bernard Myers's work had revealed a depressant action on the heart. He had abandoned it in favour of cardiazol, which was the best cardiac tonic of recent years.

Prof. DODDS pointed out that coramine only acted on the heart by way of the central nervous system.

Dr. PHILIP HAMILL said he had little doubt that cardiazol acted on the isolated heart, improving its beat. It was valuable for elderly patients undergoing anaesthesia; the depth of respiration and pulse volume were remarkably improved. He wondered whether the effect of camphor in oil was due to the very painful cutaneous stimulus caused by the ether. In animals deeply poisoned by morphia coramine and cardiazol gave striking improvement in a few moments. He asked whether they might not in the long run put an unwarrantable strain on a severely intoxicated heart.

Dr. GEORGE GRAHAM asked what change there had been in the blood pressure of patients in diabetic coma and how long it had lasted.—Prof. DODDS replied that the great thing was to control the diabetic condition; otherwise the patient would die anyhow. He personally had never used these drugs in diabetes.

Dr. E. C. WARNER recalled the case of a man who had swallowed a very large dose of camphorated liniment by mistake; at sight of the stomach-tube he had disappeared down the street and never been seen again. He agreed with Dr. Hamill that the ether in camphor injections might be significant. Myers's experiments had been on the perfused heart, thus cutting out the central effect.

The PRESIDENT said he imagined that the temporary stimulus to the circulation would be invaluable in diabetic coma.

Prof. F. R. FRASER suggested that very few physicians had ever seen a permanent effect from these injections; so far only two speakers had been able to produce examples.

Prof. L. J. WITTS described a case of pneumonia in an elderly woman with an irregular heart; 1 c.cm. of coramine every four hours had undoubtedly been followed by steady improvement.—Dr. WARNER said he also had been confident of the value of coramine in cases of pneumonia; it seemed to produce a steady rise of blood pressure—on an average 5 mm.—every 24 hours. He had also used it for dehydrated children, whose circulation definitely improved for half an hour after a dose.

Dr. PHILIP ELLMAN had had some excellent results with coramine, and believed it to be a very valuable drug.

Dr. C. W. BRASHER had had no results from maximum doses.

Dr. W. A. R. THOMSON suggested that if coramine were such an excellent drug in pneumonia the results ought to be conspicuously better in hospitals where it was used than in more conservative institutions. He asked whether coramine had affected mortality statistics or whether its effects were merely temporary.

Dr. GRAHAM referred to published work showing that pituitrin and ephedrine together raised blood pressure while neither alone had much effect.

Dr. J. W. TREVAN observed that in diabetic coma the blood contained large quantities of aceto-acetic acid which was already stimulating the respiratory centre to its maximum. He asked whether physicians wanted a respiratory or a circulatory stimulant.

Dr. THOMSON asked if any stimulant other than carbon dioxide and oxygen were needed for pneumonia.—Dr. TREVAN said that the respiratory centre might lose its sensitiveness to carbon dioxide.

Dr. E. A. SCHOTT spoke of coramine as an antidote to Somaifaine, in which it had proved very successful in one case of his.

NEW INVENTIONS

PERITONSILLAR ABSCESS OPENER

THE difficulties often experienced in opening a peritonsillar abscess are overcome by the illustrated instrument. The advantages claimed are: (1) it requires only a small opening of the mouth; (2) the instrument is introduced with the double-edged blade (B) protected in the sheath; it cannot alarm or injure the patient; (3) the blade is kept under tension

by a spring and, when released by pressing lever C, it produces a sharp and instantaneous, almost painless cut. The length of the blade can be regulated by adjusting screw A; it can be taken out for sterilisation.

This instrument is an improvement on one I described in THE LANCET of 1928, ii., 1344. Messrs. Mayer and Phelps (New Cavendish-street, W.) also make a model with an electric lamp fitted into the barrel.

ARTHUR MILLER, F.R.C.S. Edin.

London, W.

TUBERCULOSIS TREATED UNDER FAVOURABLE CONDITIONS

Dr. JACQUES ARNAUD, medical director of the Sanatorium Grand Hôtel du Mont Blanc, is on the whole encouraging about prognosis in pulmonary tuberculosis when the patient can have pneumothorax and/or sanatorium treatment (*Presse méd.*, Oct. 12th, 1935, p. 1581). His material consists of the 522 employees of the *Assistance Publique* sent from the Laennec Hospital in Paris, and treated between 1925 and 1930. They were between 20 and 50 years old, and almost all of them had undergone a compulsory clinical, radiological, and bacteriological examination at the time the disease was first discovered. Not one of them was lost sight of, and it was found that 5-10 years after the disease was first diagnosed 50 per cent. were dead, 40 per cent. were cured and fit for work, and 10 per cent. were unfit for work either because they were subject to small recrudescences of their disease or because of poor health. What subtracts somewhat from the comparatively high recovery-rate of 40 per cent. is the fact that these patients enjoyed exceptional facilities for recovery. As soon as the disease was diagnosed their work ceased, but not their salaries; and there was no sanatorium waiting-list to mock them. The cures were effected at the cost of 1-4 years' treatment—a very different matter to the three months or thereabout with which the sanatorium treatment of an older generation raised such absurdly false hopes. Eighty per cent. of all the relapses occurred within two years of resumption of work, and they were much more frequent among the patients recovering after a rest cure than among those recovering under treatment with artificial pneumothorax. Asking himself how matters can be improved, at the one end by earlier diagnosis, and at the other end by more effective treatment, Arnaud makes two pertinent suggestions. The first is a system of periodic radiological examinations of the whole community with the object of reducing the present high proportion of cases found to be already advanced when first seen. His therapeutic suggestion concerns artificial pneumothorax treatment which 99 of his 522 patients enjoyed. He believes that it could with benefit be extended to at least 40 per cent. of such patients as his.

REVIEWS AND NOTICES OF BOOKS

Clinical Tuberculosis

Edited by BENJAMIN GOLDBERG, M.D., Associate Professor of Medicine, University of Illinois College of Medicine; formerly Director, Chicago Municipal Sanitarium. Philadelphia: F. A. Davis and Co. 1935. 2 vols. Pp. 1541. \$22.

WITH the collaboration of 33 other contributors Dr. Goldberg has produced a monumental work. In a book of this composite nature the quality of the individual chapters is bound to vary and some repetitions and even a few contradictions are to be expected; but by allowing his contributors to speculate freely on hitherto unsolved problems, instead of only recapitulating well-attested facts, Dr. Goldberg has greatly added to the reader's interest, and his editorial supervision has been so wisely exercised to give the book an individuality of its own.

Of the opening chapters in the section on pathology one of the most interesting is that on bacteriology by Dr. R. R. Metchnikoff. He is an ardent believer in the new school, which no longer regards the tubercle bacillus as an unvarying entity, but as an organism possessing a life-cycle composed of several stages some of them non-acid fast and almost avirulent but capable of regaining virulence. The existence of gonidial reproductive forms, some of filter-passing dimensions, are also accepted. Dr. Mellon considers "allergy" a much overworked word and prefers to attribute the great variations in the clinical course of tuberculosis to the type of the infecting organism rather than to factors connected with the host. Further research will obviously be required before such views can be accepted. In the following chapter, on allergy and immunology, Dr. K. Robert Koch and Dr. Mellon give their opinion of BCG; they consider the crucial question here to be whether the human body will prove itself in course of time to be a suitable medium for the dissociation of the virulent from the avirulent type. Most present evidence is against this possibility, but animal experiments have not given categorical evidence for the efficacy of the culture as an immunising agent. The chapter on pathology by Dr. R. H. Jaffe, which follows orthodox lines, is clear and well illustrated. Mr. P. N. Coryllos contributes a stimulating chapter on pathological physiology; in this he discusses such questions as: Why are cavities spherical in the living and irregular in shape in the dead? What is the mechanism of their closure or occasional rapid increase in size? In answering them he shows himself to be in agreement with those who believe that many of these cavities contain air under pressure. Holding that the walls of cavities have already been studied thoroughly, he has directed his researches to their bronchial outlets which he considers to be the most important structures in the evolution of cavities. He finds that these draining bronchi always show some tuberculous lesions, varying from allergic oedema to caseous or productive changes. The lesions tend to produce stenosis of the bronchus, and a check valve mechanism may develop, allowing free ingress of air but not free egress, with the result that the cavity will increase in size. Complete bronchial obstruction will cause the cavity to shrink and disappear leaving an atelectatic portion of lung. Owing to the tubercle bacillus being a strict aerobe, requiring large amounts of oxygen for life and growth, closure of the draining bronchus should facilitate

healing. Diminished oxygenation in the affected areas of a surgically collapsed lung is considered to offer a rational and physiological explanation for the good results of this treatment. The theories put forward by Mr. Coryllos receive confirmation in a subsequent chapter on classification in which Drs. Ornstein and Ulmar describe, with X ray illustrations, "check-valve" cavities which close and subsequently reopen. One of these chapters is of particular interest; a cavity was seen to close following a hæmoptysis, the blood clot obstructing the draining bronchus was expectorated and the cavity reopened. The section on diagnosis, besides describing the physical and laboratory methods in general use, includes a full and well-illustrated chapter on X ray findings by Dr. H. E. Potter.

In dealing with treatment, Dr. Goldberg shows a preference for well-ventilated rooms rather than open air. Patients frightened of the night air are assured that the only night air that is bad is the air of the night before. The importance of rest is well emphasised, all fresh cases being given a minimum of six weeks in bed however normal the temperature and pulse. Later on graduated exercise is preferred to excessive rest as the production of flabby, fattened patients must be avoided. In a chapter on salt-restricted diet Dr. E. Mayer quotes the experience of Gerson, Hermannsdorfer, and Sauerbruch, who consider that by this treatment allergy may be reduced. Although good results are claimed the method is not an easy one to carry out, and it is to be hoped that the much simpler method of Keining and Hopf who replace NaCl by an equilibrated salt containing K, Ca, and Mg will prove of equal therapeutic value. European readers will be surprised at the scant mention of gold therapy, which Dr. Goldberg dismissed in half a page. Evidently the unfavourable report of Ambersen, McMahon, and Pinner unduly discouraged further investigations of this remedy in America. Tuberculin treatment is only considered justifiable in localised, quiescent apical lesions.

A large section (368 pages) is allotted to collapse therapy. In this chapter on artificial pneumothorax Dr. R. C. Matson says the treatment is still not used sufficiently often or sufficiently early. He also emphasises the importance of abandoning an unselective collapse unless adhesions can be severed. When an adhesion is too vascular to be divided, coagulation by diathermy near its parietal attachment often results in satisfactory stretching with subsequent refills. Oleothorax is said to give good results in about 60 per cent. of selected cases of pyopneumothorax. When employed to prevent expansion of the lung the best results are obtained where the collapse is selective and the worst where compression is necessary. Phrenic neurectomy was only used in cases in which a pneumothorax had been attempted; in 52 per cent. of these so much improvement resulted that thoracoplasty was considered unnecessary. Selective surgical apical collapse is the subject of a further chapter by Mr. Coryllos, who concludes that the results so far obtained with apical thoracoplasties are by far the best of all methods of surgical collapse. Scalenotomy was not found to be effective in closing apical cavities, and after a review of the literature of apicolysis the conclusion is reached that if cases are properly followed up cures prove to be less than 20 per cent. In discussing total thoracoplasty Mr. C. A. Hedblom considers

the higher mortality found by some authorities with right-sided cases to be due to the effect of the one-stage operation on the heart. This operative mortality may be much reduced if the operation is performed in three or more stages. The chapter on tuberculous enterocolitis by Dr. Goldberg contains an illustrated description of the early radiological diagnosis of that condition following the work of Brown and Sampson. For the control of diarrhoea injections of calcium gluconate, at first daily, later weekly, are recommended. Tuberculosis and pregnancy is the subject of an interesting chapter by Dr. F. H. Falls, who believes that, contrary to former belief, pregnancy, labour, and the puerperium have little or no effect on the course of tuberculosis. In an instructive chapter on diabetes and tuberculosis Dr. R. W. Keeton points out that, whereas in non-diabetic adults only 3 to 5 per cent. present the acute broncho-pneumonic type of phthisis, the proportion is no less than 46 per cent. in diabetics who behave in this respect like primitive races in whom production of fibrous tissue is deficient. In the management of the diabetic tuberculous insulin, combined with a high carbohydrate diet, is advocated; feeding with glucose alone being necessary in the severely ill.

Every serious student of tuberculosis will appreciate this important book.

Kurz- und Ultrakurzwellen

Biologie und Therapie. By PAUL LIEBESNY, Leiter der Physikalisch-medizinischen Abteilung des Physiologischen Instituts im Allgemeinen Krankenhaus in Wien. Berlin: Urban and Schwarzenberg. 1935. Pp. 208. RM.8.50.

THE central matter of dispute among those at present interested in the biological and therapeutic effects of ultra-short waves is the question of specificity. Whether, that is to say, the oscillations merely produce their observed effects thermally, by virtue of the random molecular movements produced when they are absorbed, or whether there are specific effects, produced only by oscillations of certain frequencies, and unconnected with the accompanying heat evolution. Some see in ultra-short wave therapy only an extension, and in certain respects an improvement, of the more familiar diathermy; others, like d'Arsonval himself—the first investigator of the biological effects of the solenoidal field—believe that it is essentially a new therapy, involving specific effects often antagonistic to the thermal ones, and not to be explained even by the different distribution of heat produced by the two methods. Dr. Liebesny belongs to the latter group, and he holds the extreme view, very concisely stated in his preface, that ultra-short wave therapy must always be “athermal”—must always be carried out under such conditions that no appreciable temperature rise takes place.

Dr. Liebesny's book, then, is to be welcomed as a readable and fairly sober exposition of the various specific effects which are said to occur: in clinical practice, where no doubt anything can be proved, as well as in far simpler systems, where at least a rigorous experimental procedure can be followed—even if a perusal of these pages suggests that it has not in fact invariably been followed. Often, however, the methods used have been undeniably ingenious, not least so in the case of Dr. Liebesny's own investigations, which are here described in some detail. And it is worthy of mention that in some instances at least

there is full theoretical support for the statement that certain observed effects could not conceivably be due solely to heat production—notably in the results of irradiation of micro-organisms.

So much for the central thesis of the book, with its extensive exposition of clinical and biological results. It should be added that the author does not exclude from consideration those applications, such as the production of artificial pyrexia, which are unquestionably due to heat production alone. As far as one can tell, the objectivity of his clinical protocols is never diminished by his adherence to a particular theory of the mechanism of short wave action.

Grundriss der Kurzwellentherapie

By Ing. Dr. WOLFGANG HOLZER, Assistent am Physiologischen Institut der Universität Wien; and Dr. EUGEN WEISSENBERG, Leiter der Kurzwellenstation an der Universitätsklinik für Nerven- und Geisteskranken in Wien. Vienna: Wilhelm Maudrich. 1935. Pp. 189. 1.8.

THIS book is divided into two parts, unequal in length and in quality. The first, by Holzer, gives a detailed account, which has all the virtues of scientific precision, of the physical and technical foundations of the production and action of ultra-short waves. The second, by Weissenberg, is a brief sketch of the present therapeutic application of these waves—extensive enough, however, to exhibit the difficulties with which clinical observation of this type has to cope.

Holzer introduces the reader to the physical aspect of the subject in a straightforward manner, without taking any special knowledge on the reader's side for granted, and yet without unduly repeating school-book information. After a simple account of the nature of oscillations, he presents with the utmost clarity the elementary properties of electrical circuits, the theory of electro-magnetic fields, and the electrical properties (specific resistance, dielectric constant) of biological material. Then the energy absorption of such materials, and its dependence on wavelength, is discussed, with an incidental discourse on the dipole theory of Debye. These preliminaries are followed by an entirely relevant review, in physical terms, of the question of specificity. The second chapter gives theoretical and practical details for the measurement of wave-length, absorption, and current intensity. The third chapter introduces short-wave technique: calculation of the constants of oscillatory circuits, advice for the construction of short wave generators and of accessories for experimental purposes. Finally, the mode of operation of powerful generators, and the precautions which have to be observed, are described. The bibliography is excellent, and in general this section of the book is to be recommended both for the originality of many of the technical details described and for the excellence of the diagrams.

Unfortunately the medical section of the book, a mere summary of the range of application of ultra-short waves, cannot be equally praised. The paragraph on the treatment of nervous diseases, in which Weissenberg is an expert, will be of interest to the specialist; the author insists on the potency of exceedingly small doses, a point on which he lays undue stress in his more recent publications. The reader will regret the omission of an adequate discussion of the experimental, physiological, and pathological basis of treatment, for which the author refers his readers to Schliephake's book.

Short Wave Therapy

By ERWIN SCHLIEPHAKE, M.D., Privatdozent for Internal Medicine at the University of Jena. Translation by R. KING BROWN, B.A., M.D., D.P.H. London: Actinic Press Ltd. 1935. Pp. 238. 21s.

THE ease with which ultra-short radio waves penetrate the body has established a place for valve generators of high-frequency oscillations in the armamentarium of the physiotherapist. This new agency is to be welcomed, since it utilises continuous waves of sinusoidal form at selected frequencies, whereas the older diathermy machine employs successive trains of damped waves involving at least two frequencies of varying form. Only by the utilisation of continuous waves of pure form can our knowledge of the mode of action of definite frequencies be analysed. Further, by the employment of very high frequencies, 20 to 100 million cycles per second, it is unnecessary to place the leading-in electrodes on the patient's skin, so that the ratio of deep to superficial treatment can be considerably increased. To accomplish this, use is made of the condenser field as suggested by Schereschewsky. Schliephake realised the immense possibilities of the application of the condenser field to the treatment of disease and he has earned the gratitude of physiotherapists for his clinical experiments both on himself as well as on patients. In his book, he presents his considered judgment on the use of ultra-short waves and the enthusiasm with which he tested out these very high frequencies on many different diseases maintains the reader's interest. His experience on the clinical uses of these short waves may well guide any who contemplate the acquisition of an ultra-short wave generator. Good generators are available in this country and some have the advantage over imported models that they possess a rectified high-tension supply instead of the raw alternating current which actually gives modulated waves. Schliephake's brief statement of the physical principles involved in the design of high-frequency oscillators is not presented with the same expert knowledge, but his account of biological experiments will serve as a useful guide to the further investigation of the action of very short waves.

Dr. King Brown's translation has appeared at an opportune moment since there are, as yet, no standard books on ultra-short wave therapy in English. He is to be complimented on producing it so quickly, but the translation would have been more readable if it were not so tied in its construction to the original of Schliephake. It is to be hoped that in any future edition greater freedom will be exercised so as to give the usual everyday phraseology of medical science. The bibliography has been curtailed which is unfortunate in so new a subject. A few misconceptions of a scientific character have arisen as a result of translation, but with this small reservation the book can be recommended as a good introduction to the subject.

Morbus Gallicus

A Bilingual Edition of the Poem *Syphilis Sive Morbus Gallicus* by Fracastoro of Verona. By LEONA BAUMGARTNER and JOHN F. FULTON. New Haven: Yale University Press; London: Humphrey Milford, Oxford University Press. 1935. Pp. 157. 22s. 6d.

THE reawakening of interest in Fracastoro's poem on the Morbus Gallicus has led to the issue of no

fewer than four independent translations in English since 1928, and the revival is further emphasised by the publication of this exhaustive bibliography which includes all the 100 known editions of Fracastoro's unique work. The title of each of these is reproduced in a modified quasi-facsimile elaborated by copious and erudite notes on authors and printers, and descriptions of the known copies of the more interesting older editions. The beautiful illustrations of title- and text-pages add greatly to the attractions of this admirable example of specialised scholarship.

The Hair and Scalp

By AGNES SAVILL, M.A., M.D. Glasg., M.R.C.P.I., Consulting Physician, Fitzroy-square Skin Hospital; formerly Physician, St. John's Hospital for Skin Diseases. London: Edward Arnold and Co. 1935. Pp. 288. 12s. 6d.

THIS book will make a wide appeal to those concerned with the preservation of the natural state, and treatment of disorders of the scalp and hair. Although primarily influenced by the teachings of Sabouraud, Dr. Savill affords continual evidence of her own wide experience and powers of observation. She has provided much information not to be found in contemporary text-books of dermatology. An entirely new departure is a section on the molecular structure and elastic properties of hair, contributed by Mr. W. T. Astbury, lecturer on textile physics at Leeds university. This interesting if somewhat abstruse study has only lately been rendered possible by X ray photographs and their mathematical analysis. At the other end of the scale is the chapter on the care of the hair, which will enlighten the physician in the mysteries of the "permanent" wave, the nature and function of "setting" lotions, and the correct methods of combing and brushing. But it must not be thought that woman alone receives consideration.

The major portion of the book is devoted to diseases of the scalp and hair, and male baldness of the common type is discussed at length with copious allusions to the work of Sabouraud, and later authorities in Germany. This section deserves praise for the effort made to render the prognosis less gloomy than the facts, or rather their absence, have hitherto seemed to justify. A detailed account is given of alopecia areata, and here Dr. Savill might be charged with a measure of inconsistency. While she warns us that "the honest medical man knows that he has not greatly influenced the course of the disease" she proceeds to offer us no less than four closely packed pages of alternative treatment, in the course of which she appears to claim at least two cures in obstinate cases of the disease. Her chapter on hair dyes is excellent and should be read by all who practise the art, and even more by those who have, occasionally, to rectify the results. One is glad to note that yet another author condemns the use of X rays in the treatment of hypertrichosis. A short appendix contains formulæ frequently required in the treatment of pityriasis, psoriasis, greasy hair, and so forth. Some of these are prescribed according to the metric system, others in the vernacular style, while a third set seems to need translation from the French. These small inconsistencies will doubtless be abolished in a future edition.

Dr. Savill is to be congratulated on a sound and informative work.

THE LANCET

LONDON: SATURDAY, NOVEMBER 16, 1935

THE CATHARTIC FUNCTION OF GENERAL ELECTIONS

MANY people who find in their work or their hobbies a satisfying outlet for their energies regard politics, and particularly general elections, as a nuisance and an interruption of the smooth and orderly run of life. They are apt to refer to them as recurring emotional crises, on the assumption presumably that political life should be conducted solely by reason in a dispassionate spirit. Observation shows that frequently those who are led by temperament to this opinion, when they do go to the polls, commonly use their opportunity to protest *against* something rather than to vote for something else. It is not easy to be dispassionate and at the same time reasonable about politics. When political science was speculative it was thought that men were by nature free, equal, and independent, and that they divested themselves of their natural liberties and put on the bonds of civil society by making an implicit agreement or social contract. If this were true the function of politics would indeed be reasonable, and Parliament would resemble a court of arbitration between the sovereign power and the people. Such is the sober wish of those non-political people to whom reference has been made, but they share the illusion of a past age. The modern trend of thought in political science is to look in another direction for a key to the understanding of the riddle of man's spasmodic interest in politics, or his dislike of it. It is obviously a far more complicated thing than any social contract, or, if we turn to biology, than the stable associations of bees or beavers, or the periodic herding of animals under the urgency of instinct.

The researches of modern psychology assist us here; they show that the great need for social life is due to the long period of dependence which characterises the young of the human species, and to the plasticity of the emotional life at that time. The desire to be a part of the community is implanted so deeply that the person who is utterly indifferent to the claims of the group is generally regarded as abnormal. The tie with society is not a contract, as LOCKE, BECCARIA, and ROUSSEAU taught, nor an expression of reflex obedience to instinct, but is highly charged with emotions of all kinds. A further complication lies in the fact that man displaces on to society many of his personal desires and ambitions. Something more than an aggregate of strength

results from the formation of a group—viz., an outlook on the future. This outlook is not a forecast based on careful observation and inference, but is a resultant of the hopes and despairs of those who form the group. Modern psychology asserts that the hopes and desires which mainly influence the electorate are not conscious ones, but are reactions which go on beneath the surface of the mind and are not influenced by reason. In his political life man responds to his personal disappointments by an attack on the Government, which represents society, and places his trust in a new and sometimes untried body of men, because he hopes from the unknown something better than the past has been able to achieve. Politics provides an outlet for pent-up personal emotions, and is a kind of safety-valve which tends to keep down the pressure of the disruptive forces.

There are great advantages as well as grave dangers in this mechanism for the de-tensioning of the mind. It leads men to the highest altruism, when they are swayed by hope and generosity; but in another mood they will ruthlessly destroy the very object they had the moment before revered. While men have these explosive and unstable unconscious-emotional forces within them, the psychologists tell us, politics will be subject to violent oscillation, and there will always be a danger of internal disruption; but the danger is diminished if there is a way of making the outlet adequate. In England this is achieved by a peculiar political device: the part of the emotional life of the individual that is concerned with politics is split into two, one portion is reserved for the Crown and all that it implies, the other for the Cabinet. Discontent, however active, does not destroy the whole of the sovereign power but only a replaceable portion of it. The Government can be turned out without disrespect to the Crown. Loyalty and anti-government feeling unite in cabinet making and in cabinet breaking. But the throne is safe so long as the Cabinet is felt to be worth attacking; the aggressive feeling is real and will not be satisfied with the figment of a Cabinet.

Apart from all its merits in providing an executive organ of government, our constitution affords a good remedy against the dangers of the accumulating discontent, which leads to revolution, by providing an efficient cathartic in the form of general elections.

PARENTERAL LIVER IN THE TREATMENT OF SPRUE

WE are laboriously learning something of how the different types of deficiency disease are brought about. The aetiological mechanisms involved in their production are gradually becoming disentangled and their exact relations in various morbid states are being determined. In the process a close relationship, already suspected on clinical grounds, between certain disease entities has been confirmed. For example, a recent detailed investigation of tropical sprue in Porto Rico by Dr. W. B. CASTLE and

three collaborators once again corroborates the many points of similarity between sprue, pernicious anaemia, and pellagra.¹ Indeed it was beyond their clinical ability to decide whether certain of the patients under observation were suffering from sprue or pernicious anaemia. They go so far as to state definitely that they can establish no distinction between the character of the blood picture found in the two conditions, whereas so experienced an observer as N. HAMILTON FAIRLEY² was able to find one. They do not appear to have discovered among their cases of sprue any evidence of the disturbance of calcium metabolism which is so constantly present in idiopathic steatorrhoea, a disorder which THAYSEN³ maintains to be identical with tropical sprue. They conclude that in sprue as in pernicious anaemia there is involved the failure of a reaction between an extrinsic factor in the diet, associated in several substances with vitamin B₁₂, and an intrinsic factor, present in the gastric contents of the normal person. This failure of reaction may be attributable to lack of extrinsic factor due to deficient diet, or to lack of intrinsic factor due to failure of gastric secretion. In addition, difficulty in the absorption of hæmopoietic factors from the alimentary canal is also present in some patients. A formidable amount of experimental evidence is marshalled to support this view. Analysis of the diets of the patients investigated showed them to be distinctly deficient in sources of extrinsic factor—namely, meat, eggs, and whole cereals. In many patients a lack of power on the part of the stomach to secrete intrinsic factor was demonstrated; in others, no reaction to the oral administration of liver extract was obtained though parenteral therapy was successful, pointing to a failure of intestinal absorption.

CASTLE and his fellow workers suggest, since the administration of defective diets to animals may produce not only a megalocytic anaemia but also profound morphological and physiological derangements of the alimentary tract, that the same may hold true in sprue and in pernicious anaemia. A deficiency of the extrinsic factor or some related substance may originally be responsible for diminishing the intrinsic factor secreted by the stomach or for producing other degenerative changes leading to intestinal impermeability. The original effect of a deficient diet would therefore subsequently be enhanced by the development of failure in alimentary secretion. In this study of sprue the possible influence of deficient diet is made obvious; in pernicious anaemia, however, apart from rare cases following operative interference, the mechanism leading to a disappearance of intrinsic factor is still not clear. Further, if this attractive hypothesis is correct, it is difficult to understand why a hypochromic rather than a hyperchromic anaemia develops in certain other anaemias where a somewhat similar dietary deficiency has been shown to be of extreme ætiological

importance, as, for instance, in the anaemia associated with hookworm infestation⁴ and in idiopathic hypochromic anaemia.⁵ The possible influence of diet on gastric function, and therefore indirectly on hæmopoiesis, may possibly prove as significant as its more direct and obvious effect, but clearly requires further investigation. Beyond dispute, anyhow, is the value of adequate dosage of liver extract, preferably given by the parenteral route, in the treatment both of the intestinal and hæmopoietic disorders of sprue. Larger doses are often required in sprue than in Addisonian pernicious anaemia, and even then the response of both reticulocytes and red cells is rather less in the former than in the latter. But CASTLE and his fellow workers believe that in every patient not proved to have a complicating infection both intestinal and hæmopoietic improvement follows the administration of parenteral liver in adequate dosage, if necessary with the addition of iron, without the use of any special diet. These views on treatment conflict with those of FAIRLEY,⁶ who not only insists upon the necessity of giving a high protein diet to all patients with sprue but is also inclined to consider oral preparations of more value than parenteral ones. But the observations from Boston are so well controlled and detailed as to suggest that provided adequate amounts of a known potent liver preparation are given, the prognosis for a patient with sprue is as good as that for a patient with pernicious anaemia irrespective of dietetic treatment.

"SURGEON"

WHAT is a "surgeon"? Has any untrained person the legal right to call himself a surgeon or does the word exclusively connote a duly qualified practitioner? The Medical Act of 1858 (as no registered surgeon needs to be reminded) was passed for the express purpose of enabling the public to discriminate between the qualified and the unqualified. With this purpose in view Section 40 protects several professional descriptions, one of which is "surgeon." Yet this title, which was meant to be the badge of duly qualified professional men, has been usurped by the unqualified. The latter indeed are claiming that a successful usurpation, lasting over the past 20 years or more, gives them a species of prescriptive right to-day. They prefix some such adjective as "osteopathic" or "manipulative" to the noun "surgeon" and declare that this hyphenation keeps them on the safe side of the prohibition in Section 40. This dubious position is due to the fact that the language of the statute is less clear than its purpose. A certain obscurity, partly accounted for by inadequate reporting, has clouded some of the decisions by which the section has been interpreted. But the clouds are being dispelled. In *Whitwell v. Shakesby*⁷ a defendant who labelled himself

⁶ *Trans. Soc. Trop. Med. Hyg.*, 1934, xxvii., 345.
⁷ *THE LANCET*, 1932, i., 1112.

"bonesetter, osteopathic physician and surgeon" was held to have infringed the statutory prohibition. And now in *Jutson v. Barrow*⁸ a defendant who labelled himself "manipulative surgeon" has met the same fate. Captain BARROW stated in the witness-box that he selected the adjective "manipulative" for the very purpose of directing attention to the fact that he was not a duly qualified surgeon within the meaning of the Medical Act. If any other name would properly describe his work, he would gladly adopt it. The Lord Chief Justice was evidently unimpressed by these protestations. Lord HEWART thought there were plenty of other descriptions—"bonesetter," for instance, or "manipulative healer"—which would achieve Captain Barrow's object. Why did unqualified men select the word "surgeon"? Was it not because of its well-known and particular connotation and association? The thing which makes the name "surgeon" appear to be attractive and useful to them, concluded Lord Hewart, is precisely the thing which Section 40 was enacted to prevent; "if this gentleman is, as we must take him to be, sincere, there are many ways of telling the public that he is not a surgeon other than the way of telling the public that he is a surgeon."

In *Jutson v. Barrow* Mr. NORMAN BIRKETT, K.C., appearing for Capt. Barrow, seems to have conceded that the use of the word "surgeon" by itself would imply that the person who used it was a registered surgeon under the Medical Act. Mr. Birkett, arguing that the addition of an adjective can change the meaning of the noun, sought to find analogies in the names "dental surgeon" and "veterinary surgeon." These names have, of course, their own statutory significance and protection. Lord Hewart would not allow any such magic to the epithet "manipulative." Every surgeon works with his hands; "to say that he is a 'manipulative surgeon' is as if it were to say he is a 'surgeon surgeon.'" At the end of the case the Lord Chief Justice added his own personal opinion that it was hard to imagine any adjective which, being added to the title "surgeon," would excuse the use of the word "surgeon" by a person not registered or recognised under the Act of 1858. Such observations clarify the legal position. The Medical Act surely intended that an offence against Section 40 would be established if it were proved first that someone had intentionally described himself as a "surgeon" and secondly that his name was not to be found on the Medical Register.

The recent decisions seem to show that this intention is being realised. "In the present case," said Lord Hewart in *Jutson v. Barrow*, "the only fact which needed to be found was: did this man call himself a surgeon?" Capt. Barrow was admittedly not registered under the Medical Act; he did not hold, and had never held, any medical degree. The obscure phrase "wilfully and falsely," which occurs in Section 40, does not require that the defendant must be proved to have acted with intent to deceive. Nobody

suggests that Capt. Barrow had any fraudulent intent. The Medical Act does not prevent him from practising; it merely stipulates that he should not confuse the public mind by using titles which the Act reserved for the use of duly qualified practitioners. The scheme of the "Council of Physical Medicine" may be mentioned in this connexion. It proposed to institute a Register for all practitioners of the healing art who are not already registered under the Medical Acts. It would admit to this Register all existing "osteopaths, chiropractors, naturopaths, manipulative surgeons, botano-therapists, herbalists, and radiologists," and for a fee of seven guineas it would grant each registered member a certificate "which will entitle the holder to be described as a Doctor of Physical Medicine and to use the initials of D.Ph.M." Is not this just the point which Lord Hewart has been criticising? "Doctor of Medicine" is, like "surgeon," one of the well-known professional descriptions which Section 40 of the Medical Act reserves for the duly qualified practitioner. "Doctor of physical medicine" seems to bear much the same relation to "doctor of medicine" as "manipulative surgeon" bears to "surgeon."

EPIDEMIOLOGY OF AN ISLAND

THE issue of a report on the public health in Iceland in the year 1933 allows some interesting comparisons to be made between the vital statistics of this little and relatively isolated community, mainly devoted to a pastoral and fishing life, and those of our own highly urbanised population for which the Registrar-General has recently issued the statistics of 1934.¹ Iceland has not been free from the world-wide economic depression and unemployment has been extensive. In spite of this the death-rate and infant mortality-rate have both been very low. The latter was in 1933 only 43 per 1000 live births, well below the 59 recorded in England and Wales in the following year. In Iceland, according to the reports of midwives, 85 per cent. of the infants born in the year were breast-fed, 5 per cent. partially breast-fed, and only 10 per cent. bottle-fed. It would be interesting to have comparable figures for this country. The stillbirth-rate of Iceland is also remarkably low, being only 21 per 1000 births, whereas in England and Wales its level since notification became compulsory has varied very little from 40 per 1000. The maternal mortality experience of the smaller country is also very favourable, the rate being 2.8 per 1000 live births in 1933 compared with 4.4 in England and Wales in 1934—though certification and grouping of the cause of death may complicate the comparison.

On the other hand, to the disadvantage of the rural community is its mortality from tuberculosis. The crude death-rate from all forms of tuberculosis, 1.5 per 1000 inhabitants, is nearly twice the rate in England and Wales, and in 1933 accounted for 15 per cent. of all deaths compared with only about

⁸ Ibid., Nov. 2nd, 1935, p. 1023.

¹ See THE LANCET, Nov. 2nd, 1935, p. 1034.

7 per cent. in this country. For a proper assessment of the difference standardised rates, or rates at ages, are necessary, but are lacking from the Iceland report. It is possible that the advantages of rural environment are severely offset by a lower standard of living. To check the spread of the disease a systematic search has been planned for carriers of tubercle bacilli and sources of infection. An initial investigation by S. SIGURDSSON in a little fishing village is reported. Here there had been a considerable spread of tuberculosis in recent years, imported, the evidence suggests, by immigrants from other parts. Pirquet tests were made on all the 77 children (aged 1-16) in the village; the 14 (or 18 per cent.) positives lived at the houses of the infection carriers or in their vicinity. Amongst 160 persons clinically examined two carriers of infection were found and it is concluded that these should be removed to a sanatorium, a strict eye kept on the Pirquet-positive children, and those at present negative retested annually to determine when and where they acquire infection. In some schools of the country a daily dose of cod-liver oil is administered, and this practice is growing. It will be interesting to see what effect this has upon the general level of health and the incidence of infectious diseases. Judging by the notifications some of the common infectious diseases of childhood disappear, rather surprisingly, for a year or two. For example, in 1924 3802 cases of measles were registered, in 1927 only 1, in 1929 a further 3026, in 1930 and 1933 none at all. Similarly there were no notifications of whooping-cough throughout 1932 and 1933, but over 6000 in 1927. Over the ten years 1924-33 the annual number of cases of mumps ranges from 0 to 1858, of German measles from 4 to 449, of scarlet fever from 5 to 624, of acute poliomyelitis from 2 to 463. Chicken-pox appears to be more constant, never falling below a hundred cases and only twice exceeding two hundred.

Some six years ago we suggested that the island² should prove a fruitful field for epidemiological investigations. The present interesting vital statistics confirm this opinion. For example, the figures suggest that diseases such as measles, whooping-cough, and mumps are unable to attain a permanent endemicity in Iceland, and epidemics are therefore limited by the exhaustion of all the available susceptibles and do not reappear till the disease is reintroduced from outside the island. It should not be difficult to collect data to prove or refute this suggestion. Again, although in the past Iceland has been decimated by small-pox, yet no case has been reported for many years. Vaccination is compulsory in the island. It would therefore be interesting to try and discover if the complete freedom from small-pox is due to vaccination or to the isolated position of the country. Few purely epidemiological investigations have been undertaken in Iceland, apart from NIELS DUNGAL's interesting observations³ on Schick immunity. DUNGAL found that in

1931 the Schick immunity of the children in the island was low, and did not rise significantly with age until they were thirteen, when the percentage of Schick-immunes rose suddenly from 17 per cent. at twelve years to 38 per cent. at fourteen years of age. Unfortunately the latter was the oldest age-group tested. This sudden step in immunity can be attributed to an outbreak of diphtheria which occurred ten years previously in 1921 and immunised the children who were over twelve years of age in 1931. On the other hand, those who oppose the latent-immunisation theory could equally well attribute this peculiar step up in immunity at the age of twelve to fourteen to a natural genetic growth process associated with the onset of puberty. The population of Iceland is about 112,000—which is half the strength of our Regular Army. This is a small enough community to allow a team of research workers, in liaison with the public health authorities, to undertake a complete epidemiological survey of the population. It should be possible to collect and record the medical history of every individual from birth to death, and to map out in space and time every case of disease. The whole population could be tested at suitable intervals with tuberculin, hydatid antigen, Schick toxin, and any other reagents. It could also be blood grouped. The distribution, movements, and changes in the bacteriological flora of man and his domestic animals could be followed in adequate samples of the population. By such means it should be possible, at a relatively small cost, to obtain for the first time a more complete ecological picture of the host-parasite relationships in a natural self-contained human community than would be practicable in any larger or less isolated natural group of human beings. We would therefore reiterate what we said in 1929: at the present moment there is in Iceland an opportunity, which will never occur again under modern world conditions, of obtaining epidemiological data of unique value.

THE next session of the General Medical Council will open on Tuesday, Nov. 26th, at 2 p.m., when Sir Norman Walker, the president, will take the chair and deliver an address. The Council will sit thereafter from day to day until their business is concluded.

THE tenth congress of the International Society of Surgery will be held, as arranged, in Egypt from Dec. 31st to Jan. 4th. The secretary-general is Dr. L. Mayer, 72 rue de la Loi, Brussels.

ON Wednesday, Nov. 20th, at 8.30 p.m., Fellows of the Royal Society of Medicine and their friends will be received by Dr. Robert Hutchison, the president, and Mrs. Hutchison. At 9.15 Sir Richard Paget will give an address on "How and why we speak." Admission will be by ticket only.

ON Nov. 28th Dr. Magarinos Torres, chief of laboratory of the Oswaldo Cruz Institute in Rio de Janeiro, will deliver a Lloyd Roberts lecture before the tropical diseases section of the Royal Society of Medicine. His title will be Further Studies on the Pathology of Alastrim and their Significance in the Variola-Alastrim Problem.

ANNOTATIONS

THE JEWISH DOCTOR IN GERMANY

A MOVING article communicated to the *Times* on Nov. 8th by a well-informed correspondent describes the increasing intensity in Germany of Jewish persecution, and shows how the encouragement given to this mass cruelty is affording chances to the anonymous informer and the blackmailer. Jewish doctors may not be more specially victimised than the Jews of any other occupation or vocation, but the doctor is particularly open to such assaults, and among the cases selected for notice by the *Times* correspondent as examples of extra-legal Jewish persecution there are certain which illustrate how vulnerable the Jewish doctor must be to the malice of fanatics, and what an easy way to pecuniary profit for the "Aryan" practitioner an agitation can be against a successful Jewish colleague. It would appear to be the intention of Nazi organisation that the Jewish doctor should be forced out of the practice of his profession in Germany. In the majority of cases the money that he may be able to take out of the country must be small, as the result of forced sales; and out of Germany he will find the opportunities for medical practice few and precarious. Hence to many German doctors the difficulty of emigration will be such that there will appear to be no alternative to slow starvation, and this among the communities where their skill and their humanity had won them regard. We cannot doubt that the great majority of our colleagues in Germany view the state of affairs with the same feelings as we experience in England. They know as well as we do that the common object of the art and science of medicine is the welfare of all men, without distinction of race or creed. We extend to them, as well as to the victims of direct persecution, our sympathy and the expression of a hope that even now this great evil may be stayed.

A NEW COLLAPSE OPERATION

It might be thought that the labours of so many clinicians over more than forty years had exhausted the possibilities of collapse operations. During this time the technique of artificial pneumothorax has changed from an elaborate operation carried out with cumbersome apparatus by a specialist in a special clinic to a simple procedure performed by the dispensary doctor. The invention of the thoracoscope has made it possible to arrest disease in many cases where persistent adhesions between lung and chest wall prevent collapse of the tuberculous focus. The introduction of paravertebral thoracoplasty has converted a hazardous operation, carried out as a last resort in desperate cases, into a procedure with a low immediate mortality which has restored many victims of chronic phthisis to a state of economic as well as physical security. Of recent years disease limited to both upper lobes has been cured by excision of the upper ribs on each side. And, despite its drawbacks, plombage has saved some patients from that most distressing end—fatal secondary hæmorrhage from a tuberculous ulcer in the lung. So far all types of thoracoplasty have followed the lines originally laid down by Spengler and Turban, and in all the operations care has been taken to excise the posterior ends of the ribs, until two years ago Monaldi began to operate on different principles. Ventilation of the lower lobe of the lung, as Keith has pointed out, is carried out by the diaphragm; ventilation of the upper lobe

by movements of the upper six ribs. Monaldi ensures rest of the lower lobe by interruption of the phrenic nerve, while ventilation of the upper lobe is suspended by excision of the antero-lateral segments of the upper six or seven ribs. In a recent account¹ of Monaldi's work, E. Berthet explains the principles involved and points out that not only is immobilisation of the diseased lung obtained but opportunity is given for the retraction and healing of recent cavities in the upper and middle zones of the lung. There is further the great advantage that the operation is in itself of less severity than paravertebral resection, as the ribs are more readily exposed, and when bone regeneration is complete the patient is again in possession of a functioning chest wall. The operation resembles the induction of an artificial pneumothorax in so far as it is not an irrevocable step. Despite the interest which this proposal will naturally excite, emphasis must be laid on its limited indications. The lesion must be in the middle or upper zone of the lung, artificial pneumothorax must be impracticable, and the disease must be of comparatively recent standing. Chronic cavities with thick fibrous walls cannot be influenced except by one of the standard operations. It is clear that the selection of cases suitable for the Monaldi operation must be left, at least for the present, in the hands of those with special experience.

ACTIVE IMMUNISATION AGAINST
POLIOMYELITIS

A FEW months ago we drew attention² to certain efforts to devise methods of specific prophylaxis against poliomyelitis. Mention was made of the vaccines of Brodie and of Kolmer and of the results obtained with the latter preparation in immunising 25 children. It will be recalled that Brodie's vaccine consisted of virus which had been rendered inactive by formalin, whereas Kolmer's contained active virus attenuated to some extent by treatment with sodium ricinoleate. At the time our leading article was written details of Brodie's work were not available, but the publication of a paper read by M. Brodie and W. H. Park³ at the eighty-sixth annual session of the American Medical Association has made good this deficiency. In this communication the authors refer first of all to the preliminary experiments on monkeys which led them to choose a formalised vaccine in preference to others. The use of sub-infective doses of live virus or of serum-virus mixtures was abandoned, because the former method carried with it the risk of infection, and the serum-virus mixtures, to be effective, had to be so nicely balanced as to make preparation on a large scale impracticable. Inactivation with formalin was found to give a safe and effective preparation, and they finally decided on virus treated with 0.1 per cent. formalin for 8–12 hours at 37°C. As evidence of the safety of their vaccine they refer not only to their experiments on monkeys, but to the immunisation of over 2300 children without mishap. In a certain number of children the development of neutralising antibody in response to the vaccine was determined. For obvious reasons these investigations were on a limited scale, but they served to indicate that one inoculation of 5 c.cm. of vaccine produced appreciable antibody in three-quarters of the children, whilst

¹ Presse méd., Oct. 5th, 1935, p. 1558.

² THE LANCET, 1935, i, 686.

³ Jour. Amer. Med. Assoc., Oct. 5th, 1935, p. 1089.

two doses evoked antibody in almost all of them. And the titre of antibody in vaccinated children compared favourably with that of children convalescent from poliomyelitis. There seems little doubt that Brodie's vaccine can be administered to children without risk and that vaccinated children develop specific antibody. One may question, though, whether these children have acquired a reasonable and durable degree of resistance to infection. Experience with other viruses has shown that formalised vaccines give only a low-grade immunity which does not last for long, and there is no reason why poliomyelitis virus should prove an exception. This is evidently the opinion of T. M. Rivers,³ for at a recent meeting of the American Public Health Association, reported in our last issue, he questioned the efficacy of Brodie's vaccine, which has now, it appears, been given to 8000 persons. He further stated that Kolmer's vaccine was unsafe since it contained active virus. Kolmer has vaccinated more than 400 children by his method in Philadelphia during the past year with, as he says, absolutely no ill-effect, and the distribution of vaccine is being proceeded with. Nevertheless the use of a vaccine containing virus so slightly attenuated does not seem to us devoid of risk and we would suggest that a safer procedure would probably be a combination of the two methods on the lines of Laidlaw's prophylactic inoculation against distemper. A primary inoculation of formalised virus would give sufficient immunity to allow of the administration of the living attenuated virus with a greater degree of security. However, both Brodie's and Kolmer's vaccines are evidently being given to children on a large scale, and no doubt these field experiments will tell us whether either of these methods is both effective and safe.

CRUCIATE LIGAMENTS OF THE KNEE

A FEW weeks ago we commented on a paper⁴ in which Milch advanced the view that the cruciate ligaments, despite their stout build and firm attachment, have little functional value. As we suggested at the time, opinions differ about the relative importance of the capsular (especially the collateral) ligaments and of the cruciate. Leemans,⁵ of La Hestre, Belgium, from experiments on the cadaver concludes that the anterior cruciate ligament does in fact come into play sooner than the capsular ligaments in limiting anterior gliding movements of the tibia on the femur. He found that in a knee-joint with the cruciate ligaments intact and the capsule removed, anterior gliding of the tibia was arrested after a movement of 6 mm.; whereas in the reverse experiment, with the cruciate ligaments removed and the capsular remaining, 10 mm. of forward movement was permitted. The difference in posterior movements was insignificant, amounting to 2 mm. only. Leemans agrees with Milch that in extension the stability of the joint depends on the action of the collateral ligaments and the posterior oblique popliteal ligament, aided by the tonic contraction of the quadriceps femoris. It is in flexion alone that the cruciate ligaments become tense; and it is in this position therefore that they must be ruptured. In the ordinary use of the limb the cruciate ligaments appear to serve no useful purpose; can it be that their presence is a relic of the stage of incomplete assumption of the erect posture? Walking with the

knee partly bent seems to call for a type of mechanical stability different from walking with the knee extended, and with the quadriceps acting at its full advantage. Hence, possibly, the vulnerability of the cruciate ligaments in ski-ing.

HEALTH INSURANCE THROUGH AMERICAN EYES

THE *New England Journal of Medicine* of Oct. 10th, 1935, contains an unsigned article, published apparently on behalf of the Public Relations Committee of the Massachusetts Medical Society, which illustrates the misconceptions of the English health insurance system that are prevalent among American doctors at the present time. The writer regards health insurance as a product of modern industrialism, which has failed "to provide sufficient wealth for every willing worker to care comfortably for himself and his family in their essential needs," and he seems to be unaware that, through the friendly societies and the mediæval guilds, health insurance has a long history as an expression of man's need for mutual aid, and that compulsory health insurance was advocated by Daniel Defoe as far back as the seventeenth century. In his account of how the English system began the writer makes an original contribution to history. It began, he says, owing to Mr. Lloyd George's fear in 1911 that he might lose "his control of the British Government" and be squeezed out of politics:—

"Then one night he sat up late reading German history, as a relaxation from the arduous labours of the day. He learned of a German statesman who several years before finding himself in much the same position hit upon the expedient of compulsory sickness insurance as a means of demonstrating his interest in and sympathy for the labouring man. He closed the book and went to bed. The German history had solved his problem and thus was born England's compulsory sickness insurance idea."

With such beginnings it is not surprising to learn that compulsory health insurance has everywhere been controlled by "an institution that appears to be the same the world over, the institution of politics." The writer doubts that the English approved societies are really non-profit making organisations; he assumes, without giving evidence for the assumption, that—

"actually costs are so manipulated that a very tidy profit is realised. Those of us who have had any contractual contacts are familiar with costs plus plans. We know how these costs may be and are juggled, and we furthermore know that from these same costs come plenty of gravy."

In describing the English system the writer falls into other curious errors. For example, a doctor wishing to undertake insurance practice must inform the Ministry of Health accordingly; maternity benefit is a payment of £1, which is paid to the husband; the expenses of a panel practice amount to £220, and so, since the average gross income from panel practice is £392, the net income is only £172. Insurance doctoring is therefore "cheap service, and at best second-class service. This is true not only in England and Germany, but in all countries harbouring systems of compulsory sickness insurance and nobody seriously questions this fact." If the writer had read the article contributed to the same journal on April 12th, 1934, by Sir Henry Brackenbury he would have seen the allegation of inferior service very seriously questioned, and indeed confuted, by one having unequalled authority to speak on the subject. The writer concludes that the introduction of compulsory health

³ Annotation, *ibid.*, Oct. 19th, p. 1275.

⁵ Presse méd., Sept. 11th, 1935, p. 1409.

insurance into the United States should be resisted by American doctors. With our experience we feel there may be worthier antagonists.

QUININE AS A CONTRACEPTIVE

DURING the past half-century quinine has probably been more widely used than any other drug for contraceptive purposes; yet it has grave disadvantages in comparison with some other substances. In the first place even the soluble quinine salts are relatively poor spermicides (J. R. Baker¹ has found several substances which are as much as 256 times as spermicidal as quinine bisulphate) and their efficiency is apparently further reduced by the vehicles in which they are usually incorporated as suppositories. Of greater significance however than this are the local and remote effects which quinine salts may have on a small proportion of the individuals using them as contraceptives. Some of these are noted by C. Booyen in a recent issue of *Marriage Hygiene*.² The local effects observed range in severity from a complaint of local irritation to an acute vaginitis with ulceration. These clinical findings are supported by the experimental work of H. M. Carleton and H. Florey³ who found that an intense vaginitis was produced in bitches by the daily introduction of quinine and urea hydrochloride into the vagina. That many substances may be absorbed from the vagina is now well established and has been proved experimentally by D. I. Macht⁴ and G. D. Robinson⁵ among others; and there seems to be no lack of clinical evidence that quinine in various forms placed in the vagina may cause severe toxic symptoms in women sensitive to the drug. Booyen quotes an interesting case reported by W. K. Ford⁶ of a male patient who developed vesicular dermatitis of the scalp, face, and neck after the application of a hair tonic. Skin tests of the ingredients of the lotion proved that quinine sulphate was the cause. A few months later, following the use by his wife of a vaginal suppository containing quinine bisulphate, he developed an oedematous vesicular dermatitis involving the penis, scrotum, eyes, cheeks, ears, and neck. These idiosyncrasies may be rare, but now that substances are available, which are not only more spermicidal but also free from any harmful local and remote effects on the users, it would seem that the time had come to abandon the use of quinine for contraceptive purposes.

THE AFTERMATH OF INJURIES

THERE is now a growing feeling that the present arrangements for dealing with injuries are wasteful and inefficient, and that much of the resulting disability is avoidable. The subject has been ventilated freely in this country during the past year. In January Dr. H. H. Kessler, of Newark, gave addresses in London on the New Jersey Rehabilitation Commission, founded in 1919 to provide medical examination, treatment, training, and placement in industry of disabled persons, including a large proportion of workmen, and a few weeks later a film was shown under the auspices of the Fellowship of Medicine, in which the work of this commission was illustrated. Two books bearing closely on the subject have since appeared; one by Dr. Kessler himself gives a detailed survey of the arrangements now in force in all the principal

countries of the world for dealing with different classes of physically handicapped persons, and the other by Mr. H. E. Griffiths contains an analysis of 50,000 consecutive cases of injury giving rise to claims under the Workmen's Compensation Acts, with some constructive suggestions. The report on the treatment of fractures, published by a special committee of the British Medical Association, has focused public attention on the deplorable results so often observed in this class of injury. This was manifest at the conference, reported on another page, where the problem of physical disability was discussed from many angles by representatives of hospitals, public health authorities, insurance companies, trade unions, and others.

It is clear that the solution of the complex questions involved cannot be attained except by the close coöperation of many different sections of the community, some of which show mutual misunderstanding and even hostility. It is common, for instance, to hear that the interests of trade unions are in conflict with those of insurance companies; that serious differences of opinion are expressed by doctors whose evidence is sought on behalf of injured persons and on behalf of employers by insurance companies; and that lawyers, doctors, and others concerned in the settlement of claims for injury tend to become absorbed in their own particular aspect of the subject and to neglect the interests of the patient. Many criticise the working of the laws, and especially of the Workmen's Compensation Acts, which are said to have become so elaborate that justice is often completely lost sight of in a jungle of technicalities. Much of the criticism is of course ill-founded. A satisfactory feature is that labour organisations are apparently out not merely to obtain adequate compensation for injuries to their members, but to establish a procedure founded on equitable principles. The Labour Party has introduced a Bill to establish a system of dealing with workmen's compensation claims on the lines practised in the State of Ontario for the past 20 years, and since adopted in principle in many of the United States of America and elsewhere. Under this scheme costs have been reduced to about 2 per cent. of the funds available (as compared with nearly 40 per cent. in this country) and the proceedings—which are conducted without the aid of lawyers and outside the courts—offer much greater advantages to the workman than are possible under our present arrangements. In spite of allegations to the contrary made during the discussion last week (see p. 1117), insurance of risks under the Workmen's Compensation and Employers' Liability Acts does not seem to be very profitable in this country. Figures published in the *Post Magazine and Insurance Monitor* for Dec. 8th, 1934, showed that about a third of the companies undertaking this business showed either no profit at all or an actual loss, and that the average profit, after allowing for expenses, was only 4½ per cent.; it was highest in the tariff companies (5.9 per cent.) and lowest in the mutual companies (0.6 per cent.).

In opening the conference on the welfare of cripples and invalid children Sir Kingsley Wood, Minister of Health, announced that the whole matter of the present arrangements for dealing with accidents and claims for injury is about to be considered by an interdepartmental committee of the Ministry of Health and the Home Office, with the following terms of reference:

To inquire into the arrangements at present in operation with a view to the restoration of the working capacity

¹ *Journal of Hygiene*, 1932, xxxii., 181.

² *Marriage Hygiene*, 1935, II., 54.

³ *Jour. Obst. and Gyn. Brit. Emp.*, 1931, xxxviii., 555.

⁴ *Jour. of Pharm. and Exp. Therapeutics*, 1928, xxxiv., 137.

⁵ *Ibid.*, 1927, xxxii., 81.

⁶ *Jour. Amer. Med. Assoc.*, 1934, ciii., 483.

of persons injured by accidents, and to report as to what improvements or developments are desirable, and what steps are expedient to give effect thereto, regard being had to the recommendations made in the report issued by the British Medical Association in February, 1935, on "Fractures."

The appointment of this committee—which was secured largely by the efforts of Mr. Geoffrey Peto, M.P., chairman of the executive committee of the Central Council for the Care of Cripples—marks an important step forward towards the provision of adequate treatment of industrial and other accident cases. It is particularly satisfactory to note the emphasis laid in the terms of reference on the "restoration of the working capacity" of such persons. This at once suggests the kind of work which is carried out by the Rehabilitation Commissions in New Jersey and elsewhere, under which schemes injured persons are not merely paid sums of money as compensation, but are taken seriously in hand by organisations, financed by the State, which ensure that as far as possible no physical handicap shall be allowed to develop or to persist longer than can be avoided, but that skilled treatment and training in industry shall be made available for all those who are so unfortunate as to be injured by accident. The experience of these commissions, as well as that of Prof. Lorenz Böhler's clinic in Vienna, has amply demonstrated that such a scheme very soon pays for itself by saving costs of compensation and maintenance of the patients; while the saving in suffering, both physical and mental, is immense. No one grudges the payment of charitable contributions to meet the needs of cripples, but it is scandalous that large numbers of persons should be allowed to drift into a condition of prolonged or permanent physical incapacity through lack of efficient and properly coördinated arrangements for treatment. Many of our own surgeons are alive to this; see, for instance, the Liverpool discussion (p. 1119). The new committee will pay great attention to suggestions put forward by those with experience of the care of the crippled and disabled.

THE HODGKIN GIANT CELL

"HODGKIN'S DISEASE" must be one of the most firmly established of eponyms and surely one of the most justifiable. In his paper entitled "On some morbid appearances of the absorbent glands and spleen"¹ Thomas Hodgkin gave the first clearly defined account of this condition, and in the main his description of the morbid anatomy of the disease which now bears his name stands good to-day. The exact histology was worked out at a later date, and here the apportionment of credit becomes more difficult. In descriptions of the well-known giant cells of the Hodgkin lesion, one of the most characteristic features of the microscopic picture, two names are often encountered: in European literature that of Carl Sternberg, who has just died in Vienna at the age of sixty-three; in America that of Dorothy Reed. Both these authors made substantial contributions to the histology of Hodgkin's disease, and accurately described the giant cells in question.² Although it would be wrong to suppose that these descriptions were novel at the time of their publication, yet they were much more accurate and detailed than any which had been given up to that time. In this country we like to give credit to

W. S. Greenfield (1846-1919) for one of the earliest correct descriptions of the histology, including the giant cells. Here are his own words.³

"Lymphatic glands.—In all five cases the change in the glands was the same in kind, though it differed in degree, in different cases and in the various glands from the same case. It consisted essentially in a sort of chronic inflammation involving especially the fibrous stroma of the gland, which became thickened and gradually obliterated entirely the interstices, so that the gland became a mass of dense, tough, fibrous tissue, with little or no trace of adenoid structure. In the early stages . . . there was some general enlargement of the glands, the fibrous stroma appeared coarser, and there were a large number of multinucleated cells adherent to the trabeculae, well seen on washing away the lymph cells. These multinucleated cells, containing from four to eight or twelve nuclei, were often collected in clusters in the parts of the gland especially where the fibrous change was progressing. . . ."

Greenfield was appointed professor of pathology in Edinburgh in 1881, and according to Boyd continued to teach there the true histology of the disease to successive generations of students. Yet even before Greenfield's description the Hodgkin giant cell was not unknown. There is a reference to it in the second edition of Wilks and Moxon's "Lectures on Pathological Anatomy" (1875)—"The very soft forms too" of Hodgkin's disease "have often large polynucleated cells, while the meshwork is delicate, so that they become very like soft carcinomas, only that the cells are not epithelioid but lymphoid." In the first edition (1859) of these lectures (by Wilks alone) Hodgkin's disease is not mentioned. Wilks "took credit to himself for having unearthed" Hodgkin's original paper,⁴ and he was mainly responsible for the introduction of the eponym. This is not in any way to belittle the importance of Sternberg's contribution to the pathology of Hodgkin's disease. Admittedly he propounded the view that it was a special type of reaction to tuberculous infection—a hypothesis not now accepted—but his description of the morbid anatomy and histology of the disease was precise and accurate and a big advance in our knowledge of an obscure subject.

Dr. J. A. RYLE will deliver his inaugural address as professor of physic in the University of Cambridge on Tuesday, Nov. 26th, at 5 P.M. He will speak on the aims and methods of medical science.

¹ Trans. Path. Soc., 1878, xxix., 272.

² Trans. Path. Soc., 1878, xxix., 269; Guy's Hosp. Reps., 1865, xxvi., 56.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Afternoon courses will be held in venereal diseases at the London Lock Hospital (Nov. 18th to Dec. 14th); in infants' diseases at the Infants Hospital (Nov. 25th to Dec. 7th); in dermatology at the Hospital for Diseases of the Skin, Blackfriars (Nov. 25th to Dec. 7th). An all-day course in proctology will be given from Nov. 25th to 30th at St. Mark's Hospital. A course will be given at the Brompton Hospital on Nov. 30th and Dec. 1st, and a special all-day course in thoracic surgery will also be given there from Dec. 2nd to 6th. For M.R.C.P. candidates there will be an evening clinical and pathological course at the National Temperance Hospital, on Tuesdays and Thursdays at 8 P.M., from Nov. 26th to Dec. 12th, and from Dec. 9th to Jan. 10th (excluding Christmas week) courses in chest diseases will be held at the Brompton Hospital and at the Victoria Park Hospital. Full information may be had from the secretary of the Fellowship, 1, Wimpole-street, London, W.1.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXVII.—PROGNOSIS OF CÆSAREAN SECTION

CÆSAREAN section, as a major surgical operation, is relatively safe; as a method of effecting childbirth, it is relatively dangerous. It is well to emphasise this; for although Cæsaean section is not, let us hope, used as an alternative method of delivery in normal cases, the indications for which it is nowadays sometimes performed appear to be extremely flimsy. The remarkable increase in the number of Cæsaean sections during the last twenty years has been due to a gradual relaxation of the indications for the operation. Formerly, contracted pelvis and obstructed labour were its only indications, but now it is done for almost every imaginable complication of pregnancy and labour. Most of the newer indications can be classed as "fœtal"; and there can be no doubt that an exaggerated idea of the value of the infant's life as compared with the life and health of the mother (due to the fact that nowadays pregnancies are spaced, regulated, and relatively rare) is having a subtle influence on modern obstetrical procedure. Cæsaean section performed for pelvic contraction in otherwise healthy young women without complications and not in labour shows a mortality of from 1 to 2 per cent.; whereas natural delivery in young women, comparable in all respects except absence of pelvic contraction, shows a mortality of from 1 to 2 per 1000. This seems to be a fair comparison and shows that Cæsaean section as a method of childbirth is only one-tenth as safe as normal labour.

It is convenient to consider the prognosis from two points of view: (1) the *immediate* prognosis: what is likely to be the mortality of the operation in the various conditions in which it is performed; (2) the *remote* prognosis: what is the risk of rupture of the scar in subsequent pregnancies and labours. Moreover, the prognosis must also be considered in relation to the type of operation performed. The *classical* operation, being easy and quick, is still being done much oftener than the *lower segment* operation which, although requiring more surgical skill and usually taking longer, is in most cases safer.

Classical Cæsaean Section

Munro Kerr and Eardley Holland in 1921 undertook an investigation into the results of classical Cæsaean sections performed in hospitals in Great Britain and Ireland during the years 1911–20 inclusive, and published the full analysis of 4197 operations.

THE MORTALITY

First and foremost must be made the essential distinction between the mortality of the operation as performed on healthy women before the onset of labour, and the mortality of the operation when performed in the presence of possible intrapartum sepsis or for complications such as eclampsia, antepartum hæmorrhage, and so on. The true mortality of the operation *per se* is obtained by taking cases in which it was performed for contracted pelvis in healthy patients who were not in labour—where, therefore, there was no risk of intrapartum sepsis due to vaginal examinations, rupture of the membranes, or prolonged labour. In such favourable circumstances the operation is a particularly safe

one in the hands of a skilful operator and in suitable surgical surroundings. But very remarkable is the progressive rise in mortality as the risk of intrapartum sepsis, or the unfavourable state of the patient, increases. In Kerr and Holland's analysis it was shown that the *maternal mortality* for cases not in labour or very early in labour was 1.6 per cent.; for cases after attempted surgical induction of labour, 14 per cent.; and after "failed forceps" the mortality reached the high figure of 26 per cent. The high mortality after cases long in labour, and especially after attempts at delivery, is an indication of the risks likely to be incurred when the operation is performed under such circumstances; but an immense factor for good or evil is, of course, the way the patient has been handled before the operation, and whether examinations and manipulations have been made with strict aseptic precautions or otherwise. The maternal mortality of Cæsaean section is almost entirely due to septic infection, leading as a rule to general peritonitis; pneumonia (probably of septic origin), pulmonary embolism, postpartum hæmorrhage, and postoperative intestinal obstruction account for a few deaths.

The *fœtal mortality* in cases in which forceps had been tried and failed amounted to 27 per cent. in the above series, and the early mortality of the infants who survived delivery was 11 per cent. The fœtal or infant mortality in such cases is from subdural cerebral hæmorrhage due to forceps-pressure. It is important to bear in mind that cerebral hæmorrhage does not affect the action of the fœtal heart, but paralyzes respiration; so that although intra-uterine existence is not interfered with (the fœtal heart will therefore be heard before delivery) the fœtus cannot breathe after birth.

PLACENTA PRÆVIA

In the treatment of placenta prævia Cæsaean section is becoming increasingly prominent. In the past it has been confined to cases of the "complete" variety, in which the bleeding is considerable and it is seldom possible to effect delivery by the natural passages, without further severe loss of blood. The operation is especially indicated in cases of complete placenta prævia in which labour has not begun and the cervix is closed and resistant. In such cases Cæsaean section performed after the first attack of bleeding is certainly less dangerous than delivery by the natural passages—besides offering almost the only chance of survival for the fœtus. But given skilled operating and the proper environment Cæsaean section need not be limited to this class of case. Provided the patient is in good condition, the mortality of Cæsaean section for placenta prævia should be no higher than for contracted pelvis—viz., 1 or 2 per cent.; the mortality of placenta prævia treated conservatively, even in skilled hands, is certainly higher than this. The tendency of modern practice is, quite rightly in my view, towards the increased employment of Cæsaean section in the treatment of placenta prævia. The position is well stated by A. H. Bill, who has recently published a series of 104 cases, 80 per cent. of which were treated by Cæsaean section, with a maternal mortality of rather less than 2 per cent. Cæsaean section is not contra-indicated by the death of the fœtus, for the operation is mainly undertaken

in the maternal interest. In order to reduce operative shock the operation should be performed under spinal or gas-and-oxygen anaesthesia, and intravenous saline or blood transfusion may be indicated during the operation.

ECLAMPSIA

When Cæsarean section is performed for other than local complications (such as pelvic contraction and other causes of obstruction, and placenta prævia) the issue becomes confused; for the prognosis of the complication when treated by Cæsarean section, rather than the prognosis of the operation itself, becomes dominant. An outstanding example is eclampsia. The recent collective investigation of eclampsia in Great Britain demonstrated, according to the analysis made by T. Watts Eden, that patients with eclampsia delivered by Cæsarean section had a mortality much greater than the average for the disease, *both in mild and in severe cases*; and it is now generally held that Cæsarean section diminishes the chances of recovery instead of increasing them.

THE RISK OF SUBSEQUENT RUPTURE OF THE SCAR

A collective follow-up investigation undertaken a few years ago into over 1000 cases of Cæsarean section performed by British obstetric surgeons between the years 1911 and 1918 inclusive has made us aware that the risk of rupture of the uterine scar is a more serious menace than was once believed. It is now known that rupture of the scar is liable to occur in about 4 per cent. of patients who become pregnant subsequently and proceed to term or near it. In the recorded cases rupture has occurred almost as often during pregnancy as during labour, and occasionally as early as the seventh month. The prime cause of rupture is imperfect healing of the uterine incision resulting in a thin scar in which muscle union has failed. Imperfect healing is due either to infection or to hurried and inefficient suturing of the uterine incision. An important point to consider in prognosis is whether a given patient may be peculiarly liable to this accident. This cannot be prophesied with certainty, and all we can say is that if there was a smooth and afebrile convalescence from an operation performed by an expert, the scar is not likely to be thin; but if the convalescence was pyrexial with signs of uterine or abdominal infection, and if the operation was performed hurriedly (and the high proportion of ruptured scars which have followed operations done hurriedly in women desperately ill from eclampsia or antepartum hæmorrhage, for example, is remarkable) the chances of rupture are higher.

When therefore the problem of how to manage a future pregnancy has to be faced, these points are to be considered. Is the saying "Once a Cæsarean always a Cæsarean" always true? By no means. If the circumstances of the last operation point to the probability of a weak scar, the patient should be advised to have another; but if the circumstances were favourable, and there is no reason to anticipate any difficulty in labour, she may be allowed to deliver herself naturally, but should be able to get prompt surgical assistance should the necessity arise.

FUTURE REPRODUCTIVE FUNCTION

A subsidiary point which emerged from the foregoing inquiry was the high percentage of infertility which followed the operation. Less than half the patients became pregnant again. This, of course, only confirmed common experience; the infertility is chiefly voluntary, because many women dread or

dislike the idea of a repeated operation. The point is an important one and deserves consideration before Cæsarean section is undertaken for a foetal indication (e.g., foetal distress, faulty presentation). If the long view is taken, the life of a single child is of small value compared with preserving the fertility of a young mother and her ability to bear children in a natural way (and as many as she wants).

Lower Segment Cæsarean Section

In this operation the uterine incision, vertical or transversely curved, is made in the lower segment after incising the uterovesical fold of peritoneum and pushing down the bladder. The operation is safer than the classical operation; for the immediate mortality is lower, and the risk of rupture of the uterine incision in subsequent pregnancy and labour and of postoperative intestinal obstruction is less. These advantages ensue because (1) the uterine wound is covered in by a thick layer of uterovesical fascia and by the bladder, and a perfect closure of the uterovesical peritoneum can be made, thus lessening in infected cases the likelihood of spread of infection from the uterus to the peritoneal cavity; (2) the wound lies in an inactive part of the uterus, and is at rest during the process of healing, giving a better chance of a strong and perfect scar; (3) the position of the wound is such that adhesions to intestine cannot easily occur.

The lower segment operation is therefore specially suitable for use in infected or potentially infected cases, and has greatly improved the prognosis in this class of case. The operation has gained favour very slowly in this country, and no large body of statistics yet exists. An analysis of 874 operations performed at the Chicago Lying-in-Hospital has been published by J. P. Greenhill, with a mortality of only 1.26 per cent.; in 50 per cent. of the cases the patients were in labour at the time of the operation, and in 20 per cent. the membranes had been ruptured for some hours. In the operations in which the indication was cephalo-pelvic disproportion (almost one-half the total) the mortality stood at the low figure of 0.8 per cent. A comparison of these figures (which are fully confirmed by other operators) with the figures already given for the classical operation leaves little doubt which is the better operation. Moreover, the lower segment operation carries a much greater protection against rupture of the scar, not more than 25 cases of rupture having been so far reported in the entire world-literature.

EARDLEY HOLLAND, M.D., F.R.C.S.,
Obstetrical and Gynaecological Surgeon,
London Hospital.

LONDON HOSPITAL.—Sir William Goschen is appealing for £80,000 for the London Hospital. New wards are required for ear, nose, and throat cases, improvements and extensions are necessary to the clinical laboratories, and the X ray department needs new equipment. The nurses' home is inadequate and must be extended, and the domestic staff require a hostel. The money is asked for immediately so that the considered plans may be put into execution.

NORTHERN WOMEN'S HOSPITAL, NEWCASTLE-UPON-TYNE.—The Duchess of Northumberland recently officially opened the new premises of this hospital in Osborne-avenue. The hospital, which has been in existence for 18 years, provides accommodation for women of small means who wish to contribute towards the cost of treatment but cannot afford the more expensive nursing-homes. During the past three years 90 per cent. of all the expenses have been covered by the patients' fees.

BRITISH MEDICAL ASSOCIATION

MEETING IN MELBOURNE

SECTION OF OBSTETRICS AND GYNÆCOLOGY

Dr. J. S. FAIRBAIRN (London), the president, opening a discussion at this section on the Prevention and Prognosis of the

Late Toxæmias of Pregnancy

defined the condition as a clinical syndrome of which raised blood pressure and albuminuria are the most prominent and constant signs, although other manifestations such as headache, vomiting, œdema, jaundice, and antepartum hæmorrhage are frequently associated. Careful clinical observation was essential before arriving at the diagnosis of toxæmia. Albuminuria, for instance, even of proved renal origin, might mean much or little. By excluding those cases whose toxic manifestations appeared before the twenty-eighth week of pregnancy, the difficulty of differentiating them from cases of chronic nephritis complicating pregnancy was to a large degree overcome. Because of our ignorance of the exciting cause, the physiological control of the condition must be empirical. Dr. Fairbairn enumerated various systems designed to prevent the condition; he himself favoured a diet rich in calcium and vitamins A and D, with additional carbohydrate in the last few weeks of pregnancy. Notwithstanding all care, however, toxæmic states would still occur; but by means of careful antenatal observation and prompt treatment many cases could be controlled in the earlier stages. The cardinal points of treatment were elimination, dietary control, and prevention of acidosis. Should the toxæmia not yield to these measures, or become intensified, the termination of pregnancy must be seriously considered.

There had been no definite fall in the maternal death-rate from eclampsia in recent years in spite of energetic treatment of patients in the "pre-eclamptic" state; eclampsia would not be entirely prevented until some means of preventing toxæmic states was available. Impending convulsions might be anticipated in cases showing a steady rise in the blood pressure, lessened secretion of urine, and severe headache, visual disturbance, or epigastric pain. Eclampsia was an acute condition of sudden onset; cases of gradual onset exhibited symptoms predominantly renal and rarely convulsions. In developed eclampsia, the prognosis depended upon the number of fits and their sequelæ. Jaundice was an unfavourable symptom. Early return of consciousness after the cessation of the fits, fall in pulse-rate, and increased secretion of urine were favourable omens. The prognosis for cases of toxic albuminuria under treatment was determined more by the daily amount of urine passed than by the actual amount of protein in the urine. Pregnancy might be allowed to continue whilst improvement was maintained. The remote prognosis for toxæmic cases depended upon the completeness of recovery. As the severity of the attack was of little moment compared with its duration, the importance of terminating the pregnancy before permanent damage resulted was apparent. The greatest care must be exercised during subsequent pregnancies, and failure of a second trial of pregnancy prohibited any further risk. Persistent high blood pressure was an unfavourable sign. A considerable foetal mortality attended all toxæmic states, being

more marked in the convulsive cases than in the non-convulsive.

Dr. JOHN S. GREEN (Melbourne) agreed that rest, elimination, and dental attention with dietary restrictions might lessen the incidence of toxæmia. In spite of all preventive treatment serious complications might ensue. The medical disability of such cases as temporarily recovered from their toxæmia was difficult to assess. There was always a tendency to improvement as time went on. The persistence of a high blood pressure and unsatisfactory urea-concentration tests suggested a latent phase which might relapse in subsequent pregnancies. In the immediate pregnancy the vast majority of cases responded promptly to treatment, but there was always a residue demanding serious consideration and often requiring interference with the course of pregnancy. Subsequent recurrence was to be expected in about one-third of all cases. The response to treatment was often at variance with the acuteness and severity of the toxæmia. Dr. Green mentioned various associated factors which might be used as a basis for the management of these toxic cases—i.e., early onset (before 35 weeks); significant past history; age and parity; bad renal function tests. If albumin persisted for longer than five days the presence of two of these factors suggested an unfavourable outcome and the presence of a third and certainly of a fourth justified immediate interference. The persistence of albuminuria with an associated high blood pressure had been suggested as a fifth factor. Consideration of these factors would be found valuable in attempts at individual prognosis regarding future pregnancy and health.

Dr. F. BROWN CRAIG (Sydney) believed that the ultimate toxic cause of the toxæmias was one elaborated in the mother's intestine—perhaps *B. coli*. Satisfactory elimination was undoubtedly a great preventive measure. Albuminuria diminished when constipation was overcome, and a well-balanced diet was always valuable. If elimination and dieting did not control albuminuria, timely induction of labour was indicated. In the primipara care and diet is more important than in the subsequent pregnancies; increased quantity of food in terms of calories was not required. With regard to maternal prognosis the death-rate of eclampsia in the Royal Hospital for Women, Sydney, was 6.9 per cent. In cases of toxic albuminuria treated by termination of pregnancy the group mortality was 15.7 per cent., which was much greater than the average. Considerably more of these cases were admitted in the winter months. Toxic albuminuria should be treated in hospital and pregnancy terminated if albuminuria did not clear up in two or three weeks. Toxæmia recurring in later pregnancies should be treated by termination and subsequent sterilisation. The main cause of death in the children of albuminuric patients was prematurity, whilst the children of eclamptic mothers were always bad risks.

Dr. KENNETH WILSON (Brisbane) held that many dietary claims had not justified themselves. Adequate antenatal supervision would largely eliminate eclampsia. He advised the early exhibition of assimilable calcium and alkalis, though admittedly some patients became toxæmic whilst taking calcium. No pregnancy should occur for at least 12 months after the disappearance of the albumin and the return of the blood pressure to normal.

Dr. MARY DEGARIS (Geelong, Vict.) said that early iliac pain was apt to pass on to pyelitic conditions,

and in some cases to albuminuria. In her view it was a mistake to starve patients suffering from toxæmia.

Prof. J. B. DAWSON (Dunedin, N.Z.) pointed out the difficulty of distinguishing the primary toxin which initiated the condition from the secondary ones which affected the parenchyma. In many pregnancies there was a very definite metabolic upset. Toxæmias occurred at the times of chorionic activity or degeneration, and he believed the chorionic elements to be the originating cause. It was quite likely that an endocrine convulsion was the starting point of these toxæmias. Some of the gravest toxæmias were associated with the development of a hydatidiform mole and it was thus possible that the anterior lobe of the pituitary gland might have a preponderating action in the development of a late toxæmia of pregnancy.

Dr. HUBERT JACOBS (Melbourne) believed that an undue increase in weight had some significance as a premonitory toxæmic manifestation.

Dr. H. A. RIDLER (Sydney) said that prognosis in these cases depended largely on good nursing.

Dr. REX MATTERS (Adelaide) urged the need of further investigation of the possible endocrine factors underlying these cases. The water metabolism factor of the posterior pituitary lobe might be very active in the toxæmias and it was this which might be decreased by the morphine therapy elaborated by Stroganoff.

The PRESIDENT spoke of the need for the establishment of a clinical research school to devise constructive methods of prevention. A consideration of the effects of treatment on already developed cases must be a very valuable guide.

Sir EWEN MACLEAN (Cardiff) opened a discussion on the Remote Results of

Puerperal Sepsis

He spoke of the difficulty of procuring accurate information on the prevalence of maternal morbidity. Little coöperative investigation was being conducted in this field. Much could be done by enlisting the good offices of the Health Organisation of the League of Nations and the larger approved insurance societies. "Remote" results of puerperal sepsis were those discovered some time after the puerperium. It would be agreed that all infected cases were associated with some degree of trauma, which served as the gateway for unresisted infection. The morbidity arising from sepsis at the time of confinement was extremely difficult to assess in actual figures because of the scantiness of the records, but had been conservatively estimated at 40,000 per annum in the British Isles. Sir Ewen referred to a table drawn up by Dr. Donald McIntyre which showed the importance of infective lesions resulting from childbearing on the reproductive tract. The conditions considered included chronic cervicitis, chronic endometritis and subinvolution, chronic salpingo-oöphoritis and pelvic cellulitis.

Chronic endocervicitis was essentially associated with traumatic lesions, great or small. Persistent infective cervical lesions led to disorder and degeneration of tissue, predisposing to malignant changes at a later date. Subinvolution was a manifestation of a very mild degree of infection, possibly unnoticed during the puerperium, which definitely lowered the fertility-rate. Sir Ewen emphasised the tendency for tubo-ovarian disease to subside and commended the general tendency of the profession to adopt conservative treatment. Chronic urinary infection was a puerperal sequela not generally afforded its

true importance because of the difficulty in tracing the infective process from "history" alone. Thrombophlebitis following puerperal infection and phlegmasia might result in very prolonged disablement and call for careful physiotherapeutic measures to ensure their complete cure.

Dr. RUFERT FURBER (Sydney) said that there was no real proof of any association between fibrosis uteri and puerperal sepsis. No microscopic inflammatory changes in the myometrium could be demonstrated even in advanced cases. Fibrosis uteri was a clinical entity associated with a halting in the process of involution. Various disturbances in lactation might be associated with its development.

Dr. ARTHUR SHERWIN (Melbourne) discussed the late results of puerperal sepsis affecting the structures adjacent to the uterus. The anatomical pathway of the spread of infection was considered—tubal involvement being by direct spread whilst broad ligament infection occurred via lymphatics and occasional thrombo-phlebitides. Many cases of salpingo-oöphoritis would resolve in time. He could not agree that gonorrhœal infection was uncommon in the upper genital tract. In his opinion the tubes were not usually involved primarily in puerperal sepsis, but were commonly involved in gonococcal conditions; the gonococcus soon died out but its effects were carried on by the secondary invaders.

Dr. N. MCL. FALKNER (Dublin) spoke of a case of mild sepsis following Cæsarean section. Hysterectomy was performed 18 months later for profuse menorrhagia which revealed a small abscess in the uterine wall around a residual silk suture. Patients with sepsis following full-term confinement often recovered completely, whilst those infected during miscarriage might show late sequelæ.

Dr. EDWARD WHITE (Melbourne) said that complete resolution of puerperal sepsis might be expected as a rule. Active treatment should be limited to medical measures, particularly medical diathermy, which was extremely useful in pelvic cellulitis. He had found vaccine therapy valuable in early chronic cases. He agreed that fibrosis uteri was a condition quite apart from puerperal sepsis; no microscopic evidence of inflammation could be adduced.

Dr. B. MILNE SUTHERLAND (Melbourne) believed that late puerperal sepsis led to much chronic ill-health and invalidism. Puerperal sepsis at full time did not as a rule lead to sterility. Mild irritation of the bladder associated with chronic puerperal cervicitis was a definite lesion calling for careful treatment. A late pelvic cellulitis might scar the parametric tissues as it resolved, constricting the ureter and leading to attacks of pyelitis. Severe congestive menorrhagia might eventually follow phlegmasia alba dolens.

The PRESIDENT said that chronic ill-health led to neurasthenia even after very minor infection, and pleaded for the consideration of the human element as apart from the pathological manifestation. The discharge of chronic cervicitis was a constant worry, whilst recurrent attacks of salpingo-oöphoritis might make a chronic invalid. Abortions were more often the cause of chronic tubal disease than were full-time pregnancies. The infecting agent in septic puerperal peritonitis undoubtedly spread by anatomical routes. Radium was the method of choice in the treatment of uncomplicated fibrosis uteri to the exclusion of hysterectomy.

Sir EWEN MACLEAN, in reply, once more emphasised the necessity for prolonged conservative treatment in these cases.

SECTION OF OPHTHALMOLOGY

Mr. A. J. BALLANTYNE (Glasgow) presided over this section when a discussion on

Glaucoma

with special reference to medical aspects and early diagnosis, was opened by Mr. H. M. TRAQUAIR (Edinburgh). He said that he would deal only with clinical experience in that form of primary glaucoma known as chronic or simple glaucoma. In his view acute and subacute glaucoma differed from chronic glaucoma in violence only, not in essential nature. The cause of glaucoma was still unknown; such conditions as hypermetropia, small cornea, and shallow anterior chamber were predisposing causes only. The chief feature of the disease was that the patients were (1) elderly, and (2) of an anxious, nervous temperament. When glaucoma occurred in the young the family history usually indicated the predominance of hereditary factors. As the disease was common in all classes of society it did not seem probable that nutritive or hygienic conditions affected it. Since both eyes were invariably affected, glaucoma should be considered as a disease of the patient—not merely one of the eye. The most usual symptom complained of was recurrent dimness of vision in one eye, and though this symptom was usually described as one of the "prodromata" of glaucoma, it was clearly a sign of the established disease. Glaucoma commenced without symptoms, and its early diagnosis depended upon the correct interpretation of the patient's early symptoms. The most difficult cases to diagnose were those that commenced insidiously; such cases were often first detected during the routine examination for glasses. Where there was any doubt, the tonometer should be used. Mr. Traquair thought that the so-called "normal" tension of 20 mm. was rather high, and he was always suspicious of eyes with a tension of over 22 mm. If a significant drop in the tension occurred after the instillation of eserine a diagnosis of glaucoma was strongly supported. In a normal eye, only a very slight fall in tension occurred. The field changes in glaucoma were sometimes of value in diagnosis—though more frequently in prognosis. Field changes were the result of the glaucomatous process, and thus could not be present until a relatively late stage of the disease. The stage before they occurred Mr. Traquair designated the "pre-perimetric stage," and he pointed out that the more expert one became in detecting field changes the shorter would be this stage.

Cases of possible or suspected glaucoma could be classified in two main groups—according to whether field changes were present or not.

GROUP 1. *No obvious or gross field changes present.*—(a) Neither symptoms nor signs present: The suspected eye appeared normal in every way, but was suspected because of definite glaucoma in the other eye. (b) Symptoms alone present: A history of haloes, periods of ocular discomfort, or other suggestive symptoms were given, but the optic disc and tension appeared normal. (c) Ophthalmoscopic signs alone present: Cupping or pallor of the optic disc, alone or together, was found in routine ophthalmoscopic examination. (d) Increased intra-ocular tension: During routine examination the tension might be found to be raised. (e) Various combinations of those features mentioned under (b), (c), and (d) might be found.

GROUP 2. *Gross and easily detected field changes present.*—Here the problem was not so much the

detection of early changes but the proper interpretation of the changes. The main point in investigation was to detect the earliest possible field change. This was done by using the weakest possible stimulus. A 1 mm. white object used at 2 metres on a Bjerrum screen was, generally speaking, the smallest reliable stimulus. The isopter for 1/2000 which normally extended for about 26° all round and included the blind spot might be contracted in early glaucoma, and if contracted to within the 12° circle, the blind spot would be left entirely outside it. Another typical change was a contraction of such degree that the field skirted around the inner side of the blind spot, leaving the upper and outer parts exposed. This was described as "barring of the blind spot," and was referred to by Sinclair as "Bjerrum's symptom." It was, in Mr. Traquair's experience, the earliest field change found in suspected glaucoma, and he had never found it apart from glaucoma, although, of course, it might possibly occur. This sign was the precursor of the typical arcuate scotoma seen in glaucoma, although the latter did not appear to grow out of the former, but appeared to arise independently on or about the 15° circle, a little distance from the blind spot. It was only in its later stages that the arcuate scotoma merged with the blind spot, and therefore it was in no way an "enlargement of the blind spot." When more fully developed, the arcuate scotoma crossed the vertical meridian and formed the "nasal step."

Mr. Traquair then briefly summarised his remarks, concluding that glaucoma should be diagnosed by the clinical picture as a whole, not by any one sign. The only pathognomonic sign was increased tension, and this was not always easily elicited.

Lieut.-Colonel R. E. WRIGHT (Madras) said that there were two main types of glaucoma, the determining factors being (1) in the anterior, and (2) in the posterior chamber. The factors that operated in the posterior chamber were (1) vitreous swelling, and (2) alterations in the vascular bed. The speaker's impression was that the former type (vitreous swelling) was more common in Indians, and the latter in Europeans, possibly owing to the vascular changes that occurred as the results of anxiety. He thought that insufficient attention had been paid to a disease, epidemic dropsy, of which glaucoma was an essential part. Research into this disease might throw light on the causes of glaucoma. Epidemic dropsy was generally considered to be a form of beri-beri, though it occurred in epidemics, and did not occur all over India, while beri-beri was endemic. Medical treatment of glaucoma was a failure, because the patients were seen too late. He knew of no medical treatment apart from massage and miotics. For the early diagnosis he thought that field changes were the most reliable sign, and to elicit these he used a Bjerrum screen, not a perimeter. In taking the tension it was very important to measure both eyes, and measurements were of no use unless bilateral. Depression of the light sense was also a valuable sign in early glaucoma if vitamin-A deficiency could be excluded.

Prof. W. A. OSBORNE (Melbourne) said that the theories of glaucoma were legion, beginning with the obstruction of the canal of Schlemm, and passing through the imbibition of gels with varying hydrogen concentration to the vogues of histamine and vitamin deficiency. He had little doubt that new theories would soon be advanced, but in his opinion the first line of attack should be an investigation of the means by which the intra-ocular pressure was kept so remarkably constant. This constant pressure

must be maintained by an oscillatory type of equilibrium, and he thought that the regulation of the standard pressure of the eye was a fundamental problem in glaucoma.

Dr. LOCKHART GIBSON (Brisbane) suggested that glaucoma was often due to a mild subthyroidism, with a mild myxœdema of the eye. He always gave his patients thyroid extract, he thought with considerable improvement.

Dr. W. F. ORR (Melbourne) doubted if tension were so all-important. He thought that an eye could stand high intra-ocular pressures without serious damage. In his opinion the field was not materially reduced while the intra-ocular circulation could be kept going, and if the choroidal veins were functioning the vision would not be impaired.

Dr. E. L. GAULT (Melbourne) said that the cause of glaucoma was still in the realms of speculation. He did not usually see patients in the very early stages, and always advised operation.

Dr. W. M. BOX (Melbourne) gave a description of Troncoso's gonioscope, an instrument for investigating the angle of the anterior chamber. He showed various drawings illustrating normal and abnormal angles, and said that in some cases of glaucoma, at least, there were no peripheral synechiæ. Blocking of the canal of Schlemm by the iris could thus have no part in the production of glaucoma in these patients.

Mr. BISHOP HARMAN (London) thought that glaucoma was essentially a disease of the eye, often due to a congenital defect. Diagnosis with the ophthalmoscope could often be better done if the illumination were reduced in intensity. He thought that the screen test was best for corroborative evidence, though it often exhausted the patient.

Mr. J. H. DOGGART (London) said he had found that pulsation of the retinal veins abolished by a miotic was a suggestive sign of early glaucoma.

Dr. E. RYAN (Melbourne) asked if anyone had any suggestion for the treatment of malignant glaucoma—those cases in which the tension remained high in spite of any interference.

Dr. RINGLAND ANDERSON (Melbourne) stressed the importance of reduced illumination in perimetry, and showed a diagram of a perimeter in which he was able to reduce the illumination at will.

The PRESIDENT did not think that all cases of glaucoma were cases of the same disease. He asked what were the signs by which the disease could be diagnosed in the preperimetric stage.

Mr. TRAQUAIR, in reply, said that he did not agree with Mr. Bishop Harman that glaucoma was primarily a disease of the eye, and he could hardly visualise a congenital defect that did not operate until the patient was middle-aged. The only sign in the preperimetric stage was increased tension.

POST-GRADUATE LECTURES

AMONG the addresses delivered at post-graduate courses in the autumn session at the London teaching schools was one by Mr. Julian Taylor of University College Hospital. It appears here in abridged form.

OBSTRUCTION IN THE COMMON BILE-DUCT

(MR. JULIAN TAYLOR)

OBSTRUCTIVE jaundice is a common symptom and a constant source of contact between surgeon and practitioner. From the patient's point of view its appearance is always a very serious event, often more serious than he suspects, as it necessarily carries with it the probability of a severe operation. From the surgeon's angle the jaundice may be on the one hand his introduction to a simple case of gall-stones with an easy, highly satisfactory, and just occasionally expensive operation, or on the other hand it may be the sign indicating the presence either of incurable disease or of formidable difficulty with uncomfortable danger. Nevertheless, in the presence of jaundice he must nearly always undertake the responsibility of performing some operation, even when confronted with whatever old or enfeebled subject, and however precarious the patient's condition it is rarely possible for him to turn tail in the exercise of his discretion.

I propose to deal with the subject of common bile-duct obstruction, starting from its cardinal symptom jaundice, and it is needless to say that its commonest cause is gall-stones. I do not presume to detail their symptomatology, which I doubt not many of you know better than I; but I would like to refer to the nature of the stones that cause it.

Stones causing jaundice are commonly primarily formed in the gall-bladder, passing thence to the bile-ducts where they may grow to large size and

where their residence may result in the formation of more stones. The stones that leave the gall-bladder for the common duct are nearly always the multiple faceted ones, as for some reason that I do not understand—although I have an idea about it—the round so-called pure cholesterol stones, whether large or small, single or multiple, rarely enter the cystic duct but seem rather to stay in the gall-bladder and there to produce their symptoms. A small faceted stone may produce the severest biliary colic, but provided that it passes to the intestine the jaundice resulting is mild and evanescent. If the stone stops in the duct the jaundice of the first attack of colic may again be evanescent but the stone grows and the further attacks of colic that it precipitates are associated with an ever-deepening jaundice of longer and longer duration, so that eventually the patient may never be completely free from yellow discoloration. Nevertheless it is possible for stones to exist for ten years or more in the common bile-duct and to produce little trouble; but we must remember that biliary obstruction results in ever-increasing distension of the passages in the liver, and in severe and long-standing cases in a fibrosis of its substance. In recurring biliary colic we thus have to envisage the possibility either of the repeated passage of stones to the intestine or of the prolonged residence of one or more in the bile-duct or ducts with the consequences to the liver arising from the prolonged halt and increasing size of the stone. In prognosis the first is hardly more serious than uncomplicated stones in the gall-bladder, while the latter, always surely indicated where the jaundice is more than evanescent, carries with it the dangers both of possible cholangitis and of depression of the liver function.

In saying that jaundice is the cardinal symptom of stones that leave the gall-bladder, may I remind you that it may also be the only one, and when jaundice without preliminary pain appears in one

past middle age it is perhaps as commonly due to gall-stones as to anything else. It is here that we may turn to cholecystography for help in the diagnosis, although we may fail to receive it. For theoretically if, in the current fashionable slang, there is pathology of the gall-bladder, the shadow of organ should not be seen in the radiogram, and most frequently it is not, as the gall-bladder is usually seriously diseased when containing multiple faceted stones. But the usefulness of cholecystography is nevertheless now firmly established largely by its caprices, and we may see a gall-bladder as an opacity surrounding stones showing themselves as translucent areas or ring-like shadows, or occasionally as an opacity not fading for 24 hours or more and thus indicating defective emptying of the organ by reason of obstruction; and very rarely we may see a common bile-duct itself depicted as an opacity linear or segmented by stones.

HEPATIC INSUFFICIENCY IN RELATION TO GALL-STONES AND THEIR TREATMENT

When Gwynne Williams in 1932 collated the figures of a collective inquiry instituted by the Association of Surgeons, he found that the mortality of operations for stone in the common bile-duct all over the kingdom was 14.65 per cent. The figure was roundly condemned as deplorable by Lord Moynihan, but the fact remains that nearly 15 per cent. died, and I feel sure that in searching for the cause we must turn to the state of the liver. Depressed function was given as the cause in no more than 16 of 91 deaths, but I believe that it was an important accessory in determining a large number of the fatalities assigned to other causes.

When after apparently successful operations for stone in the common bile-duct patients fail to make rapid recovery, in the absence of chest complications or catastrophes like peritonitis one of two things is usually happening.

First of all, where a tube is draining the common bile-duct, large quantities of fluid may escape in the form of bile. This may rapidly and completely exhaust the patient so that in 48 hours he is visibly wasted and clearly failing. We often treat the loss successfully by collecting the bile and returning it to the patient either by œsophageal or rectal tube, the latter method having surprisingly enough no enema-like action. It is likely however that the essential part of the loss that is affecting the patient is that of chlorides rather than of the special bile contents, and intravenous or rectal saline injections during the first day or so will usually suffice to prevent this occurrence or to restore condition, until mouth feeding is firmly established. That the patient is suffering from the effects of loss of chlorides may be disproved or suggested by noting their presence or absence in the urine.

The second and far more serious event is the lapse of the liver into inefficiency. When this happens the cause may not at once be recognised unless we have learned the clinical appearances of hepatic failure. The patient may make a good recovery from the operation but after a day becomes apathetic and sleeps continually, the drowsiness deepening with remissions and finally passing into a coma from which he cannot be roused. Whether previously jaundiced or not his colour soon changes to a dirty greenish-yellow tinged with an ugly cyanosis. From this condition patients may recover spontaneously but they may die rapidly or they may continue in the same state with remissions for many days. I have seen this only once in gall-stones where a hard-

drinking patient with a large liver had a stone in the common bile-duct, and I mistook it at first for post-operative cerebral thrombosis. The giving of a relatively large dose of glucose intravenously, say 30 grammes in a 5 per cent. solution, brings these people back to consciousness in a most satisfactory way.

If we believe that the functional state of the liver is the determining factor in the majority of the serious cases, the question at once arises how may we estimate its state of efficiency. I believe that at the present time little can be learned from laboratory tests unless the glycogenic function is practically exhausted, when the lævulose-tolerance test gives a clear answer. If a person swallows a quantity of lævulose he should absorb it completely in his liver so that it never reaches the general circulation. When in carrying out this test lævulose is found in the peripheral blood, the deduction is that the liver is practically out of action. We have stressed the hepatic insufficiency resulting from obstruction of the common bile-duct, but just as in prostatic disease damaged kidneys may be adequate for the body's needs, but with the onset of infection may very rapidly become gravely insufficient, so with the damaged liver the onset of cholangitis may change a case of common bile-duct obstruction from a serious but easily curable state into a most desperate business.

The subject of hepatic insufficiency naturally brings us to the question how may we attempt to obviate its disasters, and how may we treat patients so threatened. Our main resources are the general preparation of the patients for operation and the administration of glucose. In the general preparation the most important thing appears to be that we must not be in a hurry to operate but rather prepare the patient with perhaps a week or more of rest in bed, and with suitable feeding, glucose being added to the items of diet wherever possible. We delay operation not because we are frightened of jaundice, an old bugbear on which we need not lay too much stress, but because we wish to fortify the liver and to restore the patient's sugar and other metabolism, and also not less to make use of the stimulus to recuperative power that rest in bed seems always to provide. When an operation has been performed and we fear hepatic failure, it is usually sufficient to give the patient rectal or intravenous glucose injections until normal feeding is re-established, but it is rarely necessary to administer the large quantities often given by continuous infusion over many days, a method at the present time very much overdone as is our way with medical fashions. It is easily possible by the excessive intravenous or even rectal administration of fluid to produce œdema of the extremities, and remembering how many of these folk are fat, lethargic, and bronchitic, the possibility of at the same time embarrassing the lungs with watery secretion must not be forgotten.

I fear that I have overstressed the dangers attending stones in the common bile-duct but the average case is of course very different from the picture of hepatic insufficiency which I have outlined. It is obvious that the road to success in the treatment of these cases lies in the study of the group in which there is real danger, and it is perhaps fortunate that owing partly to danger to life of continued gall-stone jaundice, and partly to the visible disfigurement of the principal symptom, the surgeon is forced in almost all cases to undertake operative treatment. He will thus achieve gratifying success in many patients precariously ill; but he should remember that a

courageous operator is a surgeon with the patient's courage in his trust, and that where life is in danger operative interference should be kept to the necessary minimum directed towards restoration of liver function. There are thus cases in which the sole immediate aim of the surgeon should be the temporary drainage of the liver passages. I propose to say nothing more regarding the actual operative treatment.

ACCIDENTAL LIGATION OF THE COMMON BILE-DUCT

This next cause of obstructive jaundice follows in logical sequence preceding references to the operative treatment of gall-stones, and though I have fortunately so far no experience of the immediate results of the catastrophe I have operated upon two patients who had suffered it. In the first the duct had been incompletely occluded, and during the succeeding year he had recurring attacks of jaundice with intense itching, his condition being otherwise good. Exploring his abdomen I found that the bile-duct appeared to end in a bulbous dilatation as big as the end of one's thumb, but that leading from the duct higher up there was a narrow track passing to the duodenum and compressed by the expanded stump of the duct. The bulbous portion was joined to the duodenum by anastomosis and he made a good recovery. The second patient was in a far more serious plight and in the event she died. Aged 29, she had undergone cholecystectomy a year before and had suffered from unrelieved jaundice with itching ever since. Frail with hardly any muscle left on her bones she had a greatly enlarged liver and an intense dirty greenish-brown jaundice; her hæmoglobin was reduced to 50 per cent.; there was perpetual nausea and frequent vomiting. In her skin were many deposits of cholesterol, one of which formed a large tumour in the buttock, and in her muscles were a number of firm tumours that were hæmatomas in various stages of organisation. Three weeks were spent in preparing her for operation by administration of glucose, calcium chloride, and three blood transfusions, but we were unable to produce a satisfactory improvement in her hæmoglobin percentage. At operation no trace of the common bile-duct could be found among a mass of adhesions, only the stump of the divided hepatic duct inside the liver substance that had swollen and nearly concealed it. After freeing a small area of the duct from the liver substance it was joined to the duodenum, but she died 36 hours later, and at the post-mortem a pint of blood was found in the operation area. This patient died of a combination of hepatic insufficiency and hæmorrhage and I believe she would have had a better chance if I had attempted only the temporary drainage of the hepatic duct to the exterior, postponing anastomosis.

THE RELATION OF HÆMORRHAGE TO JAUNDICE

It is well known that jaundice favours the occurrence of hæmorrhage and it is thought that this is due to the presence of bile salts in the blood stream. There is no deficiency of calcium salts and therefore the giving of calcium before operation to prevent hæmorrhage in the presence of jaundice is probably quite useless; indeed it was administered in the last case in order that no known precaution might be omitted in a desperate situation. The two measures that seem to be useful are the administration of glucose and blood transfusion. The last case is the only one where I have encountered difficulty over hæmorrhage in jaundice, and it is to be noted that in this extreme example all known precautions were taken, but they proved inadequate to prevent the recurrence of the

oozing from the cut surface of the liver that had occurred in the operation but that had been seen to have ceased before closing the abdomen. Nevertheless, I believe that except in unusually severe cases such as this, we need not fear hæmorrhage if before the actual performance of our operations we spend a little time, say a week or so, in getting our patients into good condition by ordinary feeding, by giving glucose, and occasionally by blood transfusion.

DISEASES OF THE PANCREAS

On obstruction of the common bile-duct by disease of the head of the pancreas I do not intend to say much. The disease is commonly either chronic pancreatitis or carcinoma and in the latter case it is well known to produce obstructive jaundice with distended palpable gall-bladder, and later the evidences of pancreatic dysfunction. Yet there are cases in which the pancreatic insufficiency provides the first symptom and the biliary obstruction is late. Chronic pancreatitis on the other hand may easily be confused with gall-stones. One has seen these people with attacks of abdominal pain recurring over years and associated with jaundice. Cholecystography may show a normal or enlarged gall-bladder, and only at operation is it discovered that the pancreas is thickened either locally in the head or universally throughout the organ. It may be difficult to decide at the time of operation whether the pancreatic condition is inflammatory or carcinomatous, and on two occasions in the last year or so I have made a wrong diagnosis at operation. In one of these cases a man in his twenties had jaundice unaccompanied by other symptoms, and at laparotomy proved to have a firm enlargement of the whole pancreas thought to be inflammatory. Cholecyst-gastrostomy gave temporary relief but in a short time he died, the cause being carcinoma of the pancreas.

CYSTIC DILATATION OF THE COMMON BILE-DUCT

One other cause of obstructive jaundice may perhaps be mentioned despite its rarity. I refer to cystic dilatation of the common bile-duct, of which disease we have had in University College Hospital during the last ten years 4 cases. The condition is one in which the bile-duct is dilated either moderately to take the form of a bile-containing cyst about the size of a tangerine, or greatly to one containing gallons of bile. The reason that I wish to speak of it is that although it is only in comparatively recent times that the condition has been recognised, it often has a clear symptomatology and clinical picture.

The patients are usually women and the symptoms often begin either in childhood or adolescence. They consist of attacks of pain in the upper abdomen and back with vomiting and jaundice. Sometimes infection is superadded to the picture when there are fever and rigors; but curiously enough, although infection is common, gall-stones are rarely produced. The actual lesion present is dilatation of the common bile-duct which may be spherical or saccular, and the exact way in which the recurring attacks of biliary obstruction occur is unknown. It is thought that they may be associated with a disturbance of neuromuscular mechanism, in the walls of the biliary passages and in the sphincter at the duodenum, but it is certain that in some of the cases there are similar dilatations in the liver.

These patients respond extremely well to the making of a stoma between the cyst and the duodenum. The condition is of some importance clinically because

it is usually missed, and in two of my three cases operations had previously been done, the true nature of the cause of the jaundice not having been recognised even at operation. Recently, however, I operated upon a woman aged 38 in whom the clinical syndrome in question had been accurately reproduced in the form of pain, jaundice, and vomiting in monthly attacks since the age of 13. The cause was a congenital deformity of the gall-bladder that had resulted in external pressure on the hepatic duct.

EFFECT OF RELIEVING OBSTRUCTION

Lastly, may I say something about the disappearance of jaundice after correction or short-circuiting of obstruction in the common bile-duct. Visible jaundice sometimes takes a long time to disappear and three or four weeks after removal of a stone a tinge of jaundice may still be present. Such delay need occasion the surgeon no anxiety because it does

not signify that there is still any remaining obstruction in the duct. The effect of successful operation is nevertheless immediately felt by the patient who always finds that 24 hours after the operation, sometimes even on waking from his anæsthetic, itching has disappeared. If after an operation itching were not to disappear the surgeon would therefore at once have cause for uneasiness as it would certainly mean that the common bile-duct was still obstructed. The explanation of these well-known clinical facts probably lies in the difficulty experienced by the body fluids in removing bile deposited in the tissues rather than any delay in its disappearance from the blood stream. If therefore jaundice is rather long lasting and the surgeon has any anxiety about it, he has but to examine the blood when if the obstruction has been successfully treated no bile is found in the serum and he can prophesy a successful issue.

PANEL AND CONTRACT PRACTICE

Consultation Hours

THE terms of service provide that a practitioner shall attend and treat at the places, on the days, and at the hours to be arranged to the satisfaction of the insurance committee, any patient who attends there for that purpose. When applying to have his name included in the medical list the practitioner is required to indicate the hours and the days and places at which he will be available for consultation by insured persons. It is no part of the committee's functions to say to a practitioner who applies for inclusion in their list, "the hours you propose will not do," particularly if the applicant is merely starting practice and not buying an established practice. So long as he has no patients on his list, half an hour a day might be regarded as more than sufficient for the surgery consultation period; even if he states that he has a surgery only on certain days of the week, it might well be argued that insured persons who apply for inclusion in his list are aware of that fact and can have no cause of complaint. But in the case of a practitioner who has a number of patients it causes embarrassment to an insurance committee to find, for instance, that the doctor has no consultation period between 8 P.M. on Friday and 6 P.M. on Monday, and it is even less satisfactory to receive an application for inclusion in the list from a doctor who proposes to give a surgery period of one hour on Monday evening and one hour on Thursday evening. It would, of course, be very difficult to find a standard which would apply equally to practices of units and of thousands, but it might not be regarded as unreasonable that insurance doctors should have a definite consultation period every day, except Sundays. So many insured persons seem to be under the mistaken impression that they may see their doctor only during his recognised consultation periods that it is surely in the doctor's own interests that he should provide adequate time for surgery attendances, rather than have to make unnecessary home visits.

Prescribing Costs

Staffordshire panel committee have been drawing the attention of insurance practitioners in their area to the increasing cost of providing medicines. The letter runs:

"Well over one million prescriptions were issued in the area during the year 1934. A serious feature is the increase in the number of prescriptions issued by insurance practitioners in this county. The figures have steadily risen

from 3.67 prescriptions per insured person in 1931 to 4.07 in 1934, an increase which is not justified by comparison with the average increase in 16 other areas in the Midlands—3.72 to 3.88. For the first six months of 1935, the position is even worse. The Staffordshire increase of 0.4 per insured person represents an additional 100,000 prescriptions per annum. This addition is due not only to an increase in the number of forms issued by doctors, but also to a growing and questionable tendency to order two or more medicaments at one and the same time. Even though ordered on one form, each medicine or appliance carrying a separate dispensing fee counts as a separate prescription. This point should be borne in mind. Undue prescribing reacts unfairly on the chemists."

The reminder that when two or three medicaments are ordered on one form each medicine or appliance counts as a separate prescription and carries a separate dispensing fee is a timely one.

Spinal Jackets

Under the provisions of the Medical Benefit Amendment Regulations, 1934, an insurance practitioner may now prescribe (or supply and claim the cost of) spinal jackets when required for treatment of fractures, dislocations, or diseases of the spine. This appliance is, of course, rather expensive, and it is often much cheaper to repair a jacket than to supply a new one. Insurance committees have usually taken the view that the greater includes the less; ergo, it is proper to allow the cost of repairing a spinal jacket rather than to supply a new one, if the doctor is satisfied that the repair will make the appliance fully satisfactory. An enterprising pricing bureau has, however, drawn the attention of an insurance committee to an official letter of the Ministry dated October, 1929, in which it is stated that "no provision is made under the medical benefit regulations for the payment of the cost of repairing a prescribed appliance. The amount in question could not, therefore, be properly charged to the practitioners' drugs account, except by special sanction given as a result of an application by the insurance committee concerned."

If the position is still as indicated it is time the regulations were amended. Evidently the pronouncement of the Ministry has either been regarded with a Nelsonian eye or the official letter was sent to only one committee and safely interred in its archives, for we learn that an insured person in another area has had four spinal jackets since 1925 and repairs to his various jackets have been paid for by the insurance committee on no fewer than ten occasions—at a total cost of £34 7s. 10d.

PUBLIC HEALTH

Ultra-violet Treatment Given by Laymen

LAST month the Huddersfield town council were told that the baths' superintendent had been authorised to purchase an ultra-violet ray lamp. On which Dr. J. W. Hirst, physician to the Huddersfield Infirmary, said he thought he would be failing in his duty if he did not protest against permission being given to unqualified, unskilled people to give ultra-violet treatment without medical supervision of apparatus and persons treated. He moved that the minute be not confirmed, and his amendment was carried.

The question of the competence of a baths' committee to install ultra-violet ray apparatus arose in 1928 in Manchester and drew a wise pronouncement from Dr. R. Veitch Clark, the medical officer of health, which was reported in our columns at the time (*THE LANCET*, 1928, i., 418). He held that there was only one way in which the use of ultra-violet rays should be regarded—namely, as means of medical treatment. Unless a scheme provided for adequate medical supervision, both of the clinic and of the people who received treatment, it could not properly be adopted by a public health authority; or, one might add, by any authority or medical body responsible for the safety of the patients. Dr. Veitch Clark went on to say—and here again experience has amply proved him right—that dosage must be carefully graduated and controlled to suit each individual, if the possibility of harm is to be avoided. This control could only be effected properly by medical supervision, and the Ministry of Health had refused their approval of installation except under these conditions. Later deputations from the Manchester baths' committee visited Leeds, Bradford, and Stockport, where ultra-violet ray apparatus was installed in the public baths, and were informed that the innovation had proved a great success. There was no medical supervision while the treatment was given. The permission of the Ministry of Health for the installation had not been asked, and the medical officers of health of the three towns had raised no objections. Nevertheless, Dr. Veitch Clark stood firm and said he saw no reason to alter the views he had expressed.

Dr. Hirst's stand for adequate medical supervision revives the controversy. His protest is countered in the newspapers by statements intended to show the success obtained in Leeds, where ultra-violet ray apparatus was installed in 1927 and 100,000 treatments have been given—evidence of local satisfaction with the service. The good results are attributed by the baths' directors to employment of "trained" men to give the treatment; but this is a point on which there can be more than one opinion. It is true that skilful administration of treatment and care of apparatus present few technical difficulties, but the selection of suitable cases and the dosage for persons who suffer from some definite deviation from the normal—not merely convalescents or slightly subnormal individuals—is by no means so easy. Such tasks should not be undertaken by those who have no medical training and some acquaintance with ultra-violet therapy. The success of the Leeds scheme must be put down to the policy of working in conjunction with the medical profession and therefore to their selection of cases. Treatment is refused to anyone under medical care except on the doctor's

recommendations; cases of suspected illness are referred for medical opinion; and preliminary estimation of skin-reactions by erythema tests precede treatment. The Leeds experiment therefore closely resembles the procedure followed at many clinics, but it seems to differ nevertheless in certain important respects. In the first place the technical (non-medical) attendants are required to distinguish the normal (suitable) from the abnormal (not suitable) case. This leaves a definite possibility of serious error: for example, it is by no means easy even for the skilled medical examiner to detect the very early or the quiescent cases of pulmonary tuberculosis and to exclude them; the early case of diabetes might equally be missed; and patients with carcinoma, who sometimes show initial improvement in general health under ultra-violet treatment, might be regarded merely as persons in need of a tonic.

Stricter regulations seem to be enforced in Bradford, where it is reported that treatment is given only under a doctor's prescription. If this includes prescription of times of exposure and frequent periodic re-examination, the usual safeguards insisted upon in clinics have been adopted by this authority. Placing the apparatus in a room or building adjoining public baths presents no drawbacks, so long as its satisfactory insulation is achieved; indeed, the proximity of the baths becomes in these circumstances an advantage for the patients who will not require to undress more than once.

In arranging all the schemes, however, it seems to us essential that a medical authority should choose the apparatus and be responsible for the conditions of administration. A medical man or woman should select the patients, prescribe their irradiation, periodically inspect their treatment, and discharge them, and also take responsibility for the qualifications of the staff.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
NOV. 2ND, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2975; diphtheria, 1271; scarlet fever, 30; acute pneumonia (primary or influenzal), 822; puerperal fever, 25; puerperal pyrexia, 118; cerebrospinal fever, 11; acute poliomyelitis, 22; acute polio-encephalitis, 2; encephalitis lethargica, 5; continued fever, 1 (Paddington); dysentery, 28; ophthalmia neonatorum, 75. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the infectious hospitals of the London County Council on Nov. 8th was 3178, which included: Scarlet fever, 1184; diphtheria, 1247; measles, 59; whooping-cough, 231; puerperal fever, 20 mothers (plus 11 babies); encephalitis lethargica, 279; poliomyelitis, 10. At St. Margaret's Hospital there were 19 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 10 (0) from measles, 3 (1) from scarlet fever, 4 (2) from whooping-cough, 44 (6) from diphtheria, 56 (15) from diarrhoea and enteritis under two years, and 39 (5) from influenza. The figures in parentheses are those for London itself.

Diphtheria proved fatal in 5 cases at Liverpool, 3 at Sheffield and Birmingham, 2 at Dagenham, Ealing, West Ham, Portsmouth, Leeds, and Sunderland. Manchester reported 4 deaths from measles, Liverpool 2. Influenza is credited with 5 deaths at Manchester, 3 each at Sheffield and Birmingham, no more than 2 elsewhere.

The number of stillbirths notified during the week was 254 (corresponding to a rate of 41 per 1000 total births), including 31 in London.

CORRESPONDENCE

A FINAL APPEAL TO MEDICAL BENEVOLENCE

To the Editor of THE LANCET

SIR,—By your kindly permission I appealed to your readers in October for contributions towards our Christmas Gift Fund. I am very grateful to those who have already responded, but the amount received up to date is not sufficient to allow of Christmas gifts being given to more than a third of our beneficiaries.

The General Election is over, and Christmas is near at hand; may I therefore appeal once more in the hope that contributions will be forwarded to the hon. treasurer, Royal Medical Benevolent Fund, 11, Chandos-street, London, W. 1, lest any of our poor people be disappointed this year.

I ask all who have well-being in life to give as generously as possible and without delay, so that gifts may be distributed in time.

I am, Sir, yours faithfully,

THOS. BARLOW,

President of the Royal Medical Benevolent Fund.

Nov. 15th.

IMMUNISATION AGAINST DIPHTHERIA: ALUM PRECIPITATED TOXOID

To the Editor of THE LANCET

SIR,—In view of the increasing use of alum precipitated toxoid in connexion with diphtheria prophylaxis, it may be of interest to publish my own experience with this method during the course of the current year. The particulars are as follows:—

	Manufacturer.			Total.
	A	B	C	
Schick-negative				
1 month	162	19	3	184
after 2 months	11	—	—	11
3 „	2	—	—	2
Total Schick-negative ..	175	19	3	197

Patients Schick-negative in 1 month .. 93 per cent.

„ „ „ 3 months .. 100 „ „

Cases treated with two doses of 0.1 c.cm. A.P.T. at 1 month interval (included above under "B").

9 cases Schick-negative 1 month after last injection.

(N.B.—No pre-Schick done but all were 1-3 years old and presumably positive.)

Most of the injections were given subcutaneously and the proportion of reactions varied from 3 to 5 per cent. with different batches. None were serious.

I am, Sir, yours faithfully,

A. T. POWELL,

Nov. 9th. Medical Officer of Health, Walthamstow.

GASTROCOLIC FISTULA

To the Editor of THE LANCET

SIR,—Dr. Picton Davies, in his valuable article on Prognosis of Jejunal Ulcer published in your issue of Sept. 21st (p. 678), refers to three cases of gastrocolic fistula, all of whom died. My experience of this complication of jejunal ulcer leads me to believe that the prognosis is far less serious than these figures would indicate. We have had 7 cases of gastrocolic fistula among 90 of anastomotic ulcer in New Lodge Clinic since 1921. Of these 6 were operated upon by Sir Charles Gordon-Watson, the late Mr. R. P. Rowlands, Lord Moynihan, Sir Thomas Dunhill, Mr. Grey Turner, and Mr. Gaymer-Jones respectively, without a single death. In each

case the stomach, jejunum, and colon were separated from each other, the original anatomy being restored. In 5 nothing more was done, but in 1 an anterior gastrojejunostomy was performed. One patient subsequently had a perforated duodenal ulcer, from which he recovered. In addition a man of 64, first seen in March, 1932, 28 years after a gastrojejunostomy had been performed for a duodenal ulcer, presented definite radiological signs of a gastrocolic fistula. The usual post-ulcer régime with occasional lavage of the stomach and colon has kept him free from symptoms ever since, the fistula being apparently valvular and only giving rise to occasional trouble.

In 1928 Mr. R. C. Brock (Guy's Hospital Reports, 1928, lxxviii., 178) reported 3 cases of gastrocolic fistula following jejunal ulceration which had been operated upon by Mr. Rowlands; these included one of the New Lodge Clinic cases. He referred in his paper to 5 other cases which he had found in the Guy's records; no deaths occurred among the eight. He has kindly searched the Guy's records since 1928 and finds that 4 more cases have undergone operation with 2 deaths. The combined New Lodge Clinic and Guy's Hospital records give 17 cases with 2 deaths, a mortality of only 12 per cent. These remarkable results are of course mainly due to the exceptional skill of the surgeons concerned, but an important factor in the low mortality has, I believe, been the preparation of the patient by thorough lavage of the stomach and colon for several days before the operation.

I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, Nov. 6th.

THE INDEPENDENT MIDWIFE

To the Editor of THE LANCET.

SIR,—Your sympathetic leading article of Nov. 2nd, together with the valuable data contained in Lady Forber's Fynes-Clinton lecture, brings out very clearly the deplorable position of the private midwife. Most of those who have studied the question and read the report of the Joint Committee will concur in the view that a salaried service of whole-time midwives is likely to prove the only satisfactory way of escape from a most unhappy state of affairs. But, assuming the desirability of a service of competent midwives working under local authorities, voluntary associations, and hospitals, are there not certain questions which must be settled before it is possible to organise such a service on a national, or a compulsory, basis? For example, a successful whole-time service means in effect a limited and closed service, and therefore some control must be exercised over the number of new entrants to the profession.

The number of midwives now in practice is considerably in excess of those actually required, and in planning a midwifery scheme for any area it will not be easy to provide for the numerous midwives who, for various reasons, cannot be absorbed into the scheme. It would be unsatisfactory from the point of view of the local authority to compensate the midwives who were excluded, if newly qualified women could freely settle in the area as pin-money practitioners; neither would it be fair to continue to train many midwives who would have no chance of obtaining salaried posts. Therefore, the number of pupils, and consequently the number of training schools, would have to be reduced. If this is done,

how are the smaller maternity hospitals to be staffed, and who will make good the reduction of income from the loss of pupils' fees? Other matters which it seems desirable, if not essential, to settle concern the length and content of the training to be given to the new type of midwife who will gradually take over the work whole-time; what period it should cover; whether it should be based on general nursing or merely extend the midwifery experience; what provision should be made for the nurse who desires an additional qualification but does not wish to take up midwifery as a serious profession; how to reconcile the competing claims of the medical student and pupil-midwife for the use of clinical facilities.

There is also the question of improving and extending maternity nursing. Is it advisable to utilise the highly qualified midwife as economically as possible, and, following the example of Holland, train a body of registered maternity nurses to work for doctors and to assist the new midwives themselves?

These and other questions associated with the practice of midwifery are common knowledge; they have presumably remained unanswered because no single organisation has power and authority to deal with them. Obvious advantages will follow if the introduction of a salaried service of midwives makes it necessary not only to discuss them, but also to find a solution and remedy.

I am, Sir, yours faithfully,

Limpfield, Nov. 11th.

JANET M. CAMPBELL.

MEDICINE AND THE LAW

Medical Certificates by Deceased Practitioners

IN *Simon v. Simon* and others Mr. Justice Bucknill decided an interesting point on the evidential value of a medical certificate given by a doctor who had since died. A young woman obtained a medical certificate for a particular purpose in 1929; was it admissible in evidence for the purpose of refuting a charge against her relating to a time prior to the date of the certificate? Could it come within the rule of law which allows evidence to be given of declarations made by deceased persons in the ordinary course of their duty? Or did the usual rule against hearsay evidence govern the case and must the witness appear in open court and be cross-examined? The court decided that the certificate of the dead doctor was inadmissible. The law allows an exception where a deceased person had a duty to perform and had the duty also of recording that he had performed it. In the case under discussion the dead doctor had no duty to record the result of his examination of the young woman or to make any written statement of the result. He did undoubtedly give the certificate under his contract with the patient as any other professional man might give an opinion in the course of his practice. But this certificate was not within the exception allowed by law. Mr. Justice Bucknill thus followed Lord Merrivale's decision in *Mills v. Mills* (1920). There a charge of adultery was based on an allegation that the respondent contracted gonorrhoea in 1909 and that the petitioner was free from that disease, so that the husband could not have contracted it from his wife. Dr. N., a consulting physician who had treated the husband in 1908 and 1909, was dead. Dr. J., his successor in practice, was in possession of his case-books and notes. Dr. J. attended the court on subpoena to produce the case-book which was understood to contain the requisite information: he objected to produce the book unless

ordered by the judge to do so. "I cannot see," said Lord Merrivale, "that any duty was cast upon the consulting physician to make these entries; he was practising alone and not in partnership; he did not make the entries in pursuance of any duty to the persons consulting him nor in pursuance of any statutory order or any binding rule of the profession." Not being made under any such duty, the entries were inadmissible.

Prosecution under Venereal Diseases Act, 1917

Proceedings against Robert Vivian Storer, initiated by the Director of Public Prosecutions under the Venereal Diseases Act, stand adjourned till Nov. 28th. The charges relate to treatment of patients, and advertisement of the offer to treat patients, by a person who is not a duly qualified medical practitioner. The defendant, it was stated, was brought before the General Medical Council last May on a matter of professional discipline and it was ordered that his name be erased from the Register. The present proceedings will be more fully discussed when the case is concluded.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. H. R. S. Hull to *Malabar* for R.N. Hospital, Bermuda.

Surg. Comdrs. T. N. D'Arcy to *Victory* for R.N. Hospital, Haslar, and J. H. B. Crosbie to *Victory* for R.N.B.

Surg. Lt.-Comdrs. H. A. Clarke to *Enterprise*, and W. P. E. McIntyre to *Drake* for R.N.B.

Surg. Lt.-Comdr. J. Hamilton to be Surg. Comdr.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. (D) H. P. Buchanan to be Surg. Lt.-Comdr. (D).

Surg. Lt. K. E. L. Yuill to *Vernon*.

D. R. Maitland entered as Proby.-Surg. Lt.

ROYAL ARMY MEDICAL CORPS

Lt.-Col. C. J. Coppinger, O.B.E., having attained the age for retirement, is placed on ret. pay.

Maj. and Bt. Lt.-Col. E. A. P. Brock to be Lt.-Col.

Candidates granted short-service commissions as lieutenants on probation in the R.A.M.C.: S. J. Meyersohn, Univ. of the Witwatersrand; G. A. Weir, Glasgow Univ.; S. Brown, Edinburgh Univ.; W. N. L. Haynes and M. H. P. Sayers, St. Thomas's; W. N. J. Clarke, Queen's Univ., Belfast; J. F. Wilson, Edinburgh Univ.; P. J. Geoghegan, Univ. Coll., Cork; J. A. Dorrán, R.C. of S., Ireland; J. R. Kellett, Trinity Coll., Dublin; J. D. Cruickshank, Birmingham Univ.; C. P. Stevens, Edinburgh Univ.; J. H. Caverhill, St. Thomas's; G. A. E. Harman, Glasgow Univ.; K. G. F. Mackenzie, St. Thomas's; J. A. Farfor, Edinburgh Univ.; H. N. Perkins, St. Mary's; P. B. Hanbury and D. P. Stevenson, Guy's; A. B. Dempsey, London Hospital; and T. D. M. Martin, St. Thomas's.

TERRITORIAL ARMY

Maj. F. W. Widgery receives pay and allowances of his rank. W. Thomson (late Cadet Lee-Corpl., Glasgow Univ. Contgt., Sen. Div., O.T.C.) to be Lt.

ROYAL AIR FORCE

Flight Lt. G. M. Anderson is promoted to the rank of Squadron Leader.

Squadron Leader L. C. Palmer-Jones to R.A.F. Officers' Hospital, Uxbridge, for duty as Medical Officer.

Flight Lt. V. H. Tompkins to No. 28 (Army Co-operation) Squadron, Ambala, India.

Flight Lt. R. K. Muir relinquishes his short service commission on transfer to the I.M.S.

R. F. Courtin is granted a short service commission as a Flying Officer for three years on the active list and is seconded for duty at the Royal Victoria and West Hants Hospital, Bournemouth.

OBITUARY

WILLIAM GEORGE RICHARDSON,
F.R.C.S. Eng.

THE death of Mr. W. G. Richardson at Keswick on Oct. 27th, at the age of 72, removes an old and valued surgical member of the Newcastle school. Although educated at the Leys School, Cambridge, and a student of St. Bartholomew's Hospital, Richardson was born in Gateshead and returned to Newcastle-on-Tyne when he had obtained useful surgical experience elsewhere, and remained on the staff of the Royal Victoria Infirmary until his retirement as consulting surgeon ten years ago. His health was never robust, but he was exceptionally gifted with his fingers and his surgical results were very good, especially in difficult bone cases. His study of the prostate gland gained him the Heath prize essay in 1904, and although he wrote no book many of his interesting abdominal and cerebral cases were set out in our own columns at the time. He was always a lover of country life and it was to gratify a deep instinct of his nature that on retirement he went to settle in the Lake district.

Dr. A. W. Wakefield, one of his Keswick friends, writes:—

"It is difficult to realise that never again shall we see the familiar figure of W. G. Richardson, in an old slouch hat, riding around the district on his bicycle. Never again shall we see him hard at work in his garden, which he loved so well, and which, largely by his own personal effort, he had transformed from a rough field to an exquisite flower garden and rockery. Never again shall we interrupt him in the act of making his scientifically hung huge drive gate, or working in his rock garden, to tell him that some urgent surgical case had just been admitted to the hospital and *would* he come and do it? So often, so very often, this happened. And the response was always the same—a groan, a cheery smile, and 'must he leave his garden and get his hands clean?' And almost before one could explain the urgency, he would be at the hospital preparing for the operation. He came to Keswick professedly 'to retire.' Yet I sometimes think that he must have had almost as many emergency operations here as he had before his 'retirement.' He was always ready to help, in any way at all, and most of this work was gratuitous. In fact he had the way of almost making it appear that one was doing him a favour in asking him for help. And on seeing the patient how kindly and sympathetic, how thoughtful and how thorough he was in his examination.

"But his activities were not confined to his garden and his surgery. He loved our Lakeland, he loved our hills, and he loved walking over them and exploring them. The view from the house which he built for himself at Portinscale is lasting evidence of his eye for natural beauty. And besides all this he threw himself whole-heartedly into the local activities and interests. He was a member of the rural district council, and besides being the life and soul of the Keswick and District Bee Keepers' Association, he took an active part in the local horticultural society, the Braithwaite debating society, and the Portinscale reading-room. Whatever he did was done with all his might—always happy, a cheerful smile for everyone, deeply lamented by everybody of every class and creed."

Mr. Richardson married Sarah, daughter of Dr. George Arnison of Allendale Town, who predeceased him. There were no children of the marriage.

THOMAS DUTTON, M.D. Durh., M.R.C.P. Edin.

Dr. DUTTON, who died in London on Monday at the age of 81 years, had lived a varied and strenuous life. Born in Pimlico and educated at Bayswater Grammar School and Guy's Hospital, he went on to Scottish universities, qualifying in Edinburgh in 1878 and taking the Durham M.D. four years later. He was then for several years in the mercantile marine, acting as surgeon on the *Elysia*, *Tongariro*, and *Argonaut*, and later admiralty surgeon and agent for the Chichester division. On his return to London he practised in Holland Park, being active in medical politics, and becoming a consulting physician with special interest in diseases of the digestive organs and in the eradication and care of tuberculosis. In his early days he had taken up yachting and swimming—he was an amateur champion—and his writings covered a large range of subjects on the practice of healthy living. He published a popular book on "Voyaging for Health," and a treatise on "Indigestion Clearly Explained," which ran into several editions, and a handbook on "The Food and Rearing of Children," which also was reprinted several times. Papers on diet, alcohol, hygiene, and tuberculosis appeared in our own columns. He remained in practice until his death, being honorary physician to a welfare clinic in Uxbridge-road. He was also vice-chairman of the Pure Food Society.

JOHN MONRO GIBSON, F.R.C.S. Eng., who died at the Hospital of St. Nicholas and St. Martin at Pyrford, Surrey, of broncho-pneumonia, was son of Dr. H. Wilkes Gibson, formerly in practice in South Hampstead. He was educated at Rugby School and University College, Oxford, where he was an honorary scholar of his college and won the Theodore Williams scholarship for anatomy. He went on to St. Thomas's Hospital from which he qualified in 1920, and held the post of surgical registrar there after residence at the Surrey County Hospital. He then accepted a commission in the R.A.M.C. which he was obliged to relinquish on account of ill-health and became resident medical officer at Pyrford, where he was able to carry on orthopaedic work until a few days before his death at the age of 30 years.

Dr. GEORGE YOUNG, who died at Colchester on Oct. 30th after an operation, was ophthalmic surgeon to the Essex County Hospital and well known as a musician. He was educated at Zurich and Philadelphia, taking his Swiss degree in 1901 and qualifying in this country from the London Hospital in the following year. Turning to ophthalmology, after some experience in London, he went to New York where he became assistant surgeon to the Eye and Ear Infirmary, and ophthalmic surgeon to the Central and Neurological Hospital, taking the M.D. of New York State in 1908. For a time he lectured on physiological optics at Oxford University, and for the last 20 years was in charge of the department at Colchester, where he designed the new ophthalmic clinic opened ten years ago, which is one of the best things of its kind. Dr. Young was equally at home on the piano and violin, and he was able to accompany distinguished violinists like Albert Sammons to their entire satisfaction. In his spare time he used to make violins. He was only 60 years of age.

MEDICAL NEWS

Royal College of Surgeons of England

The annual meeting of fellows and members will be held at the College in Lincoln's Inn-fields, London, on Thursday, Nov. 21st. On behalf of the Society of Members of the College Dr. C. Luther Battenon will move, and Dr. Richard Gillbard will second, a resolution affirming that in the opinion of the meeting members should be represented on the council.

University of London

At meetings of the senate on Oct. 23rd Dr. W. D. Newcomb was appointed associate examiner in pathology at the M.B., B.S. examination in November, and Mr. C. B. Goulden, Mr. R. Foster Moore, and Prof. E. D. Telford examiners for ophthalmology in the M.S. examination in December. Dr. A. M. H. Gray was appointed a governor of the British Postgraduate Medical School, and Sir Ernest Graham-Little, Prof. H. R. Kenwood, and Sir Holburt Waring, members of the court of governors of the London School of Hygiene and Tropical Medicine.

On Dec. 2nd, 4th, and 5th at 5.30 p.m. at the London School of Hygiene and Tropical Medicine, Keppel-street, W.C., Major-General Sir John Megaw will lecture on neglected aspects of public health work with special reference to India.

University of Liverpool

The title of emeritus professor has been conferred on Mr. W. H. Gilmour who retired at the end of last session from the Louis Cohen chair of dental surgery.

University of Sheffield

Mr. T. B. Moutat, F.R.C.S., has been appointed lecturer in surgery to dental students, and Mr. Wilfred Hynes, F.R.C.S., has been appointed to the honorary demonstratorship in operative surgery which Mr. Moutat has resigned. The following external examiners have been appointed:—

Anatomy, Prof. D. M. Blair; physiology, Prof. H. S. Raper, F.R.S.; pharmacology, Prof. A. D. Macdonald; medicine, Dr. J. W. McNeer; surgery, Prof. G. E. Gask; public health, Prof. J. Johnstone Jervis; forensic medicine, Prof. J. E. W. MacFall; dental subjects, Prof. T. Talmage Read, and (for Ph.D. thesis) Sir Norman Bennett.

Royal College of Physicians of Edinburgh

At a quarterly meeting of the college held on Nov. 5th, with Dr. Edwin Bramwell, the president, in the chair, Dr. Helen May Russell (Edinburgh) was introduced and took her seat as a fellow. Sir Harold Gengoult Smith (Melbourne, Australia) and Dr. Sidney Solomon Rosebery (Sydney, N.S.W.) were elected to the fellowship. The Hill Pattison-Struthers bursary in anatomy and physiology was awarded to John Tolland, and the Wood bursary to C. C. Gardner.

The college will shortly award a Kirk Duncanson fellowship for medical research, of which further particulars will be found in our advertisement columns.

Royal Free Hospital

The annual reunion dinner of the old students of the London School of Medicine for Women will be held on Thursday, Nov. 28th, at the Savor Hotel at 7 for 7.30 p.m. Dr. Letitia Fairfield and Commander Stephen King-Hall will be among the guests.

Royal Society of Arts

At an ordinary meeting of this society to be held on Jan. 15th, 1936, at 8 p.m., Mr. L. H. Lampitt, D.Sc., will discuss Food and the World. On Feb. 10th, 17th, and 24th, at 8 p.m., Major-General Sir Robert McCarrison will give three Cantor lectures on Nutrition and the Nation. The address of the society is John-street, Adelphi, W.C.2.

Dental Clinics in Sweden

An official proposal is put forward for the establishment of dental clinics throughout Sweden, with the object of ensuring that everyone's teeth shall be under the care of the State from the age of three onwards. The country would be divided into 425 dental districts with a total of 575 district dentists, the yearly cost being estimated at over 7 million kroner (about £370,000), of which 4.65 million kroner would be borne by the State.

Infants Hospital

A course in infants' diseases for medical officers of welfare centres and others interested in nutritional disorders and dietetics will be given at the hospital, Vincent-square, S.W., from Nov. 25th to Dec. 6th.

Society of Medical Officers of Health

The annual dinner of this society will be held at the Piccadilly Hotel, London, on Friday, Nov. 22nd, at 7.30 p.m., with Dr. W. G. Savage, the president, in the chair. Sir George Newman will be the guest of honour, and Sir Kingsley Wood, Minister of Health, intends to be present.

British Health Resorts Association

The annual general meeting of this association will be held at the Institute of Hygiene, 28, Portland-place, London, W.1, at 4 p.m. on Thursday, Nov. 28th, with Lieut.-Colonel R. H. Elliot in the chair. The general secretary is Dr. Alfred Cox, and he may be addressed at 199, Piccadilly, W.1.

Royal Dental Hospital

The 26th annual clinical at home of this hospital will be held on Saturday, Nov. 23rd. During the morning there will be demonstrations at the hospital and at Charing Cross Hospital, while in the afternoon there will be exhibitions of clinical cases and specimens.

Glasgow University Club, London

The annual dinner of this club will be held at the Trocadero Restaurant, Piccadilly, W., on Friday, Dec. 6th, at 7.15 for 7.30 p.m., with Prof. J. Graham Kerr, F.R.S., in the chair. Any Glasgow University men who, though not members of the club, desire to attend, are asked to communicate with the hon. secretaries, 62, Harley House, N.W.1.

Research Scholarship in Tuberculosis

A Walton Marsh Barnes research scholarship on the biochemistry of tuberculosis, tenable in the pathological department of the City of London Hospital for Disease of the Heart and Lungs, Victoria Park, E., will shortly be awarded. The scholarship is of the value of £500 for the first year, and may be held for a further two years with annual increments. Applications should reach the secretary of the hospital by Nov. 29th.

Prize in Anaesthetics

The *British Journal of Anaesthesia* is offering a prize of ten pounds for the best essay on any subject concerned with the administration or physiology of anaesthetics submitted before August 1st. The essays should not exceed 4000 words in length and candidates must possess a medical qualification within the British Empire. Further particulars may be had from the editor of the journal at 19, St. Andrew's Mansions, Dorset-street, London, W.1.

St. George's Hospital, London

On Nov. 5th Miss Marie Tempest opened the new ward at this hospital for the use of the theatrical profession, which is the result of the matinée given at Drury-lane to celebrate her fifty years on the stage. The ward is to be called after her.

A cheque for £746 has been received from the management of Grosvenor House, Park-lane, which is the hospital's share of the gate-money of the Antique Dealers' Fair.

Ulster Medical Society

At the opening meeting of this society on Oct. 24th Dr. S. R. Hunter, on retiring from the chair, welcomed the newly elected president, Dr. Foster Coates, who gave an address on the importance of vitamins in dietetics. Referring to vitamin-D deficiency he pointed out that where there was much sunshine less vitamin was required in the diet; whereas in polar regions, where the sunlight was less intense and the body more completely clothed, the function of protection passed from the light to the diet. In Britain to-day the adaptation of diet to climate was incomplete. At the close of his address Prof. R. J. Johnstone and Sir Thomas Houston proposed and seconded a vote of thanks.

Warneford Hospital, Leamington

An anonymous donor has given £1000 for the endowment of two cots at this hospital. The fund for the new maternity block amounts at present to £4174.

Prince of Wales's Hospital Club

The annual dinner of the club of The Prince of Wales's General Hospital, Tottenham, will be held at the Trocadero Restaurant on Thursday, Nov. 28th, at 7.45 for 8 p.m., with Mr. Norman Fleming in the chair. The hon. secretary of the dinner is Mr. A. Lowndes Yates 36, Harley-street W.1.

Lectures on Tropical Hygiene

A course of lectures and demonstrations on tropical hygiene will be given by Lieut.-Colonel H. B. Newham, Mr. H. H. Clay, and Sir Malcolm Watson from Dec. 2nd to 12th at 4 p.m. for men and women outside the medical profession who are proceeding to the tropics. Further information may be had from the organising secretary of the Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine, Keppel-street, W.C.1.

International Congress of Physical Medicine

The sixth international congress of physical medicine will meet in London from May 12th to 16th. Lord Horder will preside over the British section and other officers will be: Sir Robert Stanton Woods (chairman of the executive committee), Sir Henry Gauvain (chairman of the general committee), Dr. Albert Eidinow (hon. secretary), and Dr. Alexander Cavadias (hon. assistant secretary). Further details may be had from Dr. Eidinow at 4, Upper Wimpole-street, London, W.1.

Medico-Chirurgical Society of Edinburgh

The following officers have been elected for the coming session: president, Dr. David Huskie; vice-presidents, Dr. John Orr and Mr. W. J. Stuart; councillors, Mr. Norman Dott, Dr. Rae Gilchrist, Mr. C. F. W. Illingworth, and Dr. C. W. Somerville; treasurer, Mr. Walter Carlow; secretaries, Mr. J. J. M. Shaw and Dr. T. R. R. Todd; and editor of *Transactions*, Dr. A. Fergus Hewat.

At a meeting to be held on Dec. 3th Sir Lancelot Barrington-Ward will address the society on the diagnosis and treatment of acute abdominal conditions in childhood.

Libraries in Hospitals

A meeting of the Guild of Hospital Librarians was held at St. Thomas's Hospital on Oct. 31st. Hospital libraries owe their origin to the war library started by Sir Hagberg Wright and Mrs. Gaskell in 1914 for the supply of books to the sick and wounded and the Red Cross is continuing the work. Dame Rachel Crowdy, vice-president of the guild, appealed for more books and more trained librarians. It is hoped to hold the second annual general meeting of the guild in Paris next year.

New Hospital at Hereford

The Herefordshire public assistance committee on Oct. 30th adopted a scheme for the erection at Hereford of a hospital which will provide wards for the sick to replace the accommodation at the poor-law institution, suitable maternity wards, accommodation for advanced cases of tuberculosis, and a new venereal clinic. The annual maintenance is estimated at £1200, and the scheme will cost in all £54,000.

Lectures on Child Health

A second series of ten weekly lectures has been arranged by the Jewish Health Organisation, and will be given at 8.30 p.m. on Saturdays at the Whitechapel Art Gallery, High-street, London, E., from Nov. 23rd to Jan. 25th. Dame Louise McIlroy will deliver the opening lecture on antenatal care, and other speakers will be: Dr. R. C. Jewesbury (care of the infant in the first two years of life), Dr. Bernard Myers (physical and mental welfare of the pre-school child), Dr. M. D. Eder (care of the child in relation to his studies), Dr. H. Harris (play in childhood), Mrs. Susan Isaacs, D.Sc. (mental welfare of the child), Mrs. Winifred Raphael (welfare of the worker), Prof. V. H. Mottram (domestic hygiene), Mr. Phineas Quass (protection of the worker), and Prof. Samson Wright (care of the adolescent). The lectures are open to all and no tickets are needed.

The Rogers Prize

An award of this prize will be made next year and candidates are invited to submit essays on the treatment of the sick poor of this country, and the preservation of the health of the poor in this country, or either of these subjects. Further particulars will be found in our advertisement columns.

Appointments

CARTER, HAROLD, M.B., F.R.C.S. Edin., M.C.O.G., has been appointed Medical Superintendent of the Central Middlesex County Hospital.

DENNY-BROWN, D. E., M.B. N.Z., M.R.C.P. Lond., Assistant Neurologist to St. Bartholomew's Hospital, London.

JONES, N. ROBYN, M.B. Camb., F.R.C.S. Edin., Assistant Orthopaedic Surgeon to the Prince of Wales' Orthopaedic Hospital, Cardiff.

LEWIS, EMLYNE, F.R.C.S. Eng., Resident Surgical Officer at the Hospital for Consumption, Brompton.

THOMAS, H. A., M.B. Liverp., D.P.H., Medical Officer of Health for the County of Debnish.

Gordon Hospital, Faulkhill Bridge-road, S.W.—The following appointments are announced:

HUTCHINSON, MAURICE, M.B. Lond., Hon. Anaesthetist;

JOHNSON, E. F., M.B. Lond., Hon. Anaesthetist; and

MORRIS, L. H., M.R.C.S. Eng., Hon. Anaesthetist.

Certifying Surgeons under the Factory and Workshop Acts: Dr. A. MACKINTOSH (Sunderland District, Durham); Dr. F. WIGGLESWORTH (Howden District, County of York East Riding).

Births, Marriages, and Deaths

BIRTHS

ANDERSON.—On Nov. 5th, at Homsey, the wife of Roy S. Anderson, M.R.C.S. Eng., of a son.

BARTLETT.—On Nov. 9th, at Saffron Walden, to Elsie, wife of Dr. Justinian Bartlett—a son.

BATCHELOR.—On Nov. 4th, at Putney Hospital, to Marjorie (née Radkin), wife of J. S. Batchelor, F.R.C.S. Eng.—a daughter.

COPEMAN.—On Nov. 7th, at Devonshire-place, W., the wife of Dr. William S. C. Copeman, of Ferncroft-avenue, N.W., of a daughter.

FRANKLYN.—On Oct. 31st, at Bradford, the wife of Dr. Harold Franklyn, of a son.

GOLDEN.—On Nov. 4th, the wife of Gerald N. Golden, F.R.C.S. Eng., of Haslemere, Surrey, of a son.

SATCHWELL.—On Nov. 4th, at North Curry, Somerset, Bristol, the wife of R. E. Satchwell, M.B., of a son.

SINGER.—On Nov. 2nd, at Greenhithe, Kent, the wife of Major E. O. A. Singer, R.A.M.C., of a daughter.

WIGFIELD.—On Nov. 5th, at Buntingford, Herts, the wife of Alan Wigfield, M.B. Lond., of a son.

MARRIAGES

CARR—CHRISTOPHERSON.—On Nov. 8th, at the Parish Church, Reigate, Claude Morris Carr, M.B. Camb., of Reigate, to Audrey Lorna Clifford, second daughter of Mr. and Mrs. Dudley Clifford Christopherson, Reigate Hill.

LEECH-WILKINSON—KINGDON.—On Nov. 4th, at Chelsea Parish Church, Arthur Leech-Wilkinson, B.M. Oxon., F.R.C.S. Edin., 11, The Circus, Bath, to Joan Kingdon, younger daughter of the late Mr. F. W. Kingdon and Mrs. Kingdon.

THOMPSON—STENHOUSE.—On Nov. 2nd, at West Lulworth, Dorset, Geoffrey Thompson, M.D., to Ursula Stenhouse.

GOLDEN WEDDING

TAIT—GREENWAY.—On Nov. 12th, at St. Andrew's Church, Plymouth, by the Rev. Preb. Wilkinson, D.D., and the Rev. B. Liptrott, M.A., William Tait, M.B. Edin., R.N., H.M.S. Cambridge, youngest son of the late George Tait, of Kirkcubright, Allowick, to Emma, eldest daughter of John Greenway, of Shaftesbury Villas, Ford Park, Plymouth. Present address: Kirkcubright, Alverstoke, Hants.

DEATHS

COATES.—On Nov. 1st, in London, after an operation, George Coates, D.M. Oxon., of South Kilworth, Rugby and Borden, Italy, aged 84.

CRESSY.—On Nov. 8th, at New Milton, Hants, Charles James Cressy, M.R.C.S. Eng.

LITGOW.—On Nov. 7th, at Farnborough, Hants, Thomas George Litgow, F.R.C.S. Edin., aged 82.

TEMPLETON.—On Nov. 2nd, at Bexhill-on-Sea, Percy Templeton, M.R.C.S. Eng.

WHITWELL.—On Nov. 3rd, at Church Stretton, George Graves Whitwell, M.B. Edin., late of Shrewsbury.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Nov. 19th.

General Meeting of Fellows. 5.30 P.M. Ballot for election to the fellowship.

Pathology. 8.15 P.M. (Group and Central Histological Laboratories at Archway Hospital (L.C.C.), Archway-road, N.). E. N. Allott: 1. Alkalosis in the Treatment of Gastric Ulcer. J. M. Alston: 2. Human Cases of Infection with an Organism resembling *B. necrophorus*. 3. Skin Reactions Produced by *Pneumococcus* Polysaccharide. W. G. Barnard and R. F. L. Hewlett: 4. Agranulocytosis. A. B. Bratton: 5. Anuria with Haemoglobin Casts in Kidneys following Abortion. 6. Dissecting Aneurysms of Aorta at 14 and 32 years. 7. Carcinoid Tumour of Small Intestine Associated with Carcinoma of Colon. H. C. Brown and J. M. Alston: 8. Demonstration of Antibodies to *L. icterohæmorrhagiae* in Human Serum. G. W. Goodhart and R. F. L. Hewlett: 9. Three Cases of Monocytic Leukæmia. 10. Case of Myeloblastic Leukæmia. 11. Case of Congenital Malaria. E. Hardy: 12. An Infection of Guinea-pigs due to *Bact. aertrycke*. L. F. Hewitt: 13. Electrode Potentials. J. E. McCartney: 14. Screw-capped Bottles for Culture Media. 15. Intravenous Solutions and a Simplified Method for their Administration. W. Mair: 16. Varieties of *C. diphtherie*. A. B. Rosher: 17. The Carrier Rate of Haemophilic Bacteria in the Trachea of Post-mortem Subjects correlated with the Influenza Death-rate during the last seven years. 18. The Use of Chocolate-tellurite Medium for the Diagnosis of Diphtheria. A. B. Rosher and E. Hardy: 19. The Persistence of Agglutinins in the Blood of Inoculated Subjects in Relation to the Serological Diagnosis of Enteric. E. W. Todd: 20. Antistreptolysin Titrations.

THURSDAY.

Dermatology. 5 P.M. (Cases at 4 P.M.) Dr. H. W. Barber: 1. Schamberg's Progressive Pigmentary Dermatoses. 2. Pigmentation of the Leg Secondary to Varicose Veins. Dr. C. H. Whittle: 3. Schaumann's Disease. 4. Pemphigus Vulgaris. 5. Carcinomatosis of the Skin. Dr. Elizabeth Hunt: 6. Xanthoma Tuberosum Multiplex.

Neurology. 8.30 P.M. Prof. E. D. Adrian, F.R.S.: Electrical Activity of the Cortex. Mr. J. H. Quastel, D.Sc.: Enzymic Activity of the Brain.

FRIDAY.

Disease in Children. 5 P.M. (Cases at 4.30 P.M.) Dr. P. Evans (for Dr. W. Sheldon): 1. Portal Cirrhosis. 2. Biliary Cirrhosis. Dr. G. H. News: 3. Infantile with Complete Hypospadias. Dr. R. Wilson (for Dr. D. Paterson): 4. Actinomycosis of the Lungs. Mr. R. M. Walker: 5. Total Pulmonectomy for Bronchiectasis. Dr. Maycock (for Dr. D. Paterson): 6. Late Rickets.

PADDINGTON MEDICAL SOCIETY.

FRIDAY, Nov. 22nd.—3.30 P.M. Visit to the Metropolitan Police Laboratory, Hendon.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

FRIDAY, Nov. 22nd.—2.30 P.M. (11, Chandos-street, W.). Dr. C. P. Blacker: Discussion on the Report of the Departmental Committee on Sterilisation. Other speakers: Dr. D. Blair, Dr. W. A. Potts, Dr. P. K. McCowan, Dr. D. McRae, Dr. W. J. T. Kimber, and Dr. T. Power.

HUNTERIAN SOCIETY.

MONDAY, Nov. 18th.—9 P.M. (Cutlers' Hall, Warwick-lane, E.C.4). The Bishop of St. Albans, Dr. C. P. Blacker, Dr. Halliday Sutherland, and Mr. E. R. T. Clarkson: That Birth Control is unnecessary in Modern Life.

EUGENICS SOCIETY.

TUESDAY, Nov. 19th.—5.15 P.M., rooms of the Linnean Society, Burlington House, Piccadilly, W. Mr. J. V. Quilliam, Mrs. C. B. S. Hodson, and Dr. C. P. Blacker: Voluntary Sterilisation—the Work of the last two years.

ROYAL SOCIETY OF TROPICAL MEDICINE AND

HYGIENE, Manson House, 26, Portland-place, W.

THURSDAY, Nov. 21st.—8.15 P.M., Dr. Eric de Verteuil and Prof. F. W. Ulrich: The Study and Control of Paralytic Rabies transmitted by Bats in Trinidad.

TUBERCULOSIS ASSOCIATION.

FRIDAY, Nov. 22nd.—5.15 P.M. (Manson House, 26, Portland-place, W.). Sir St. Clair Thomson: Tuberculosis of the Upper Respiratory Tract. Mr. R. E. Bickerton: Tuberculosis of the Eye. 8.30 P.M. Dr. E. L. Middleton and Dr. P. Heffernan: Industrialism and Tuberculosis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

VICTOR HORSLEY LECTURE.

TUESDAY, Nov. 19th.—5 P.M. (University College Hospital Medical School, Gower-street, W.C.), Sir Walter Langdon-Brown: Integration of the Endocrine System.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE

MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, Nov. 18th, to SATURDAY, Nov. 23rd.—INFANTS HOSPITAL, Vincent-square, S.W. Mond., Wed., and Fri., 8 P.M. Course in anatomy and physiology for the F.R.C.S. (Primary).—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. All-day course in medicine, surgery, and gynaecology.—LONDON LOCK HOSPITAL,

91, Dean-street, W. Daily, 3 P.M. and 6 P.M., course in venereal disease.—Courses are open only to members of the fellowship.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C. MONDAY, Nov. 18th, and TUESDAY.—2.30 P.M., Dr. David Nabarro: Diagnosis of Congenital Syphilis for School Medical Officers.

THURSDAY.—2 P.M., Dr. E. A. Cockayne: Fever of Obscure Origin. 3 P.M., Dr. W. Payne: Diabetes (IV.), Diabetes and the Ductless Glands.

Out-patient clinics daily at 10 A.M. and ward visits (except on Wednesdays) at 2 P.M.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Nov. 18th.—3.30 P.M., Dr. Symonds: Intracranial Pressure.

TUESDAY.—3.30 P.M., Dr. Critchley: Epilepsy and Allied Conditions.

WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.

THURSDAY.—3.30 P.M., Dr. Walshe: The Motor System (II.).

FRIDAY.—3.30 P.M., Dr. Gordon Holmes: Disorders of Vision (I.).

Out-patient clinics daily at 2 P.M.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, N.W.

WEDNESDAY, Nov. 20th.—4 P.M., Dr. H. Courtney Gage: Radiology of the Genito-urinary Tract.

KING'S COLLEGE HOSPITAL, Denmark Hill, S.E.

THURSDAY, Nov. 21st.—9 P.M., Mr. John Everidge: Genito-urinary Tuberculosis.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

NOTES, COMMENTS, AND ABSTRACTS

KWASHIORKOR

A NUTRITIONAL DISEASE OF CHILDREN ASSOCIATED WITH A MAIZE DIET

BY CICELY D. WILLIAMS, B.M. Oxon., M.R.C.P.,
D.T.M. & H. Lond.

THE name "kwashiorkor" indicates the disease the deposed baby gets when the next one is born, and is the local name in the Gold Coast for a nutritional disease of children, associated with a maize diet, which was first described in December, 1933.¹ An attempt is here made to compare the disease with other conditions, and to indicate the differential diagnosis.

Kwashiorkor is usually observed between the ages of six months and four years, the youngest case noted being nine weeks and the eldest five years old. Some sixty cases have been observed in three years among patients at the Children's Hospital, Accra, the mortality being about 90 per cent. The history always includes defective feeding. The mother is sick, old, and malnourished, or has become pregnant again while the patient is still very young; or the mother may have died, breast-feeding being supplied by an unsuitable foster-mother, very often a senile grandmother; for among these African women some mammary secretion may be present in a woman who has not had a child for 20 years. Supplementary feeds consist mainly of a gruel made from partially fermented white maize, called *arkasa*, or, for older children, a thick dough of the same called *kenki* or *kon*. The child at first appears to progress normally. After a variable interval it ceases to gain weight and becomes

irritable. Some swelling of the hands and feet and face appears. This always passes off, both in the event of improvement and in the terminal stages of fatal cases. There may be attacks of diarrhoea; there may be photophobia; and there was sloughing of the cornea in two cases. The most obvious feature is the skin condition. Small, black, thickened, crumpled patches appear first about the knees and elbows, afterwards along the extensor sur-

FIG. 1.—A half-caste child, aged 5, suffering from kwashiorkor, with sores at the corners of the mouth.

faces and the buttocks. These are areas exposed to irritation and pressure. They have no relation to exposure to light, in contrast to the lesions of pellagra. The skin is soft and pliant, but tends to peel off, leaving a moist, raw surface. There is no "branny desquamation." Small sores at the corners of the eyes and mouth and about the vulva are usual. There may be a trace of albumin in the urine. Malaria, bronchitis, and worms are frequent complications; in uncomplicated cases there may be a slight irregular pyrexia. The blood count is little affected; there is no great anaemia and no leucocytosis. The W.R. is negative. Post mortem the only constant

finding is an extreme fatty infiltration of the liver.

Cases seen very early react well and promptly to an improved diet, rich in accessory substances. Nestlé's sweetened condensed milk with cod-liver oil and malt seemed to be the most successful line of treatment. Unfortunately the condition is an insidious one, and once the dermatitis has set in there is not much hope of recovery. Butter, eggs, tomato, orange, liver, Marmite, yeast, Bemax, iron, and arsenic have also been tried in the treatment.

Figs. 1 and 2 show the condition in a half-caste child of five who died two months later. It is just possible to see the sores at the corners of the mouth. The dark thickened patches of skin are seen on the legs and buttocks. There are none in the areas typical of pellagra. The microphotographs are of the liver (Fig. 3) and of a section of skin (Fig. 4) from the same case. Some points in the differential diagnosis between kwashiorkor and pink disease, vitamin-A deficiency, pellagra, and vitamin-C deficiency are set out below.

DIFFERENTIAL
DIAGNOSIS*Pink disease.*—

Characteristics common to pink disease and kwashiorkor, both of which occur in young children, are irritability, irregular pyrexia, and skin lesions. The latter reacts well to early treatment, whereas the former runs a prolonged course, unaffected by treatment. In kwashiorkor photophobia is seen only occasionally, skin lesions are distinct and typical, and desquamation is extensive, deep, and severe; whereas in pink disease photophobia is pronounced, skin lesions are different, and desquamation is slight.²

Vitamin-A deficiency.—Characteristics common to both kwashiorkor and vitamin-A deficiency are the lack of animal fats in the diet, the occurrence of skin lesions, attacks of enteritis, and improvement under cod-liver oil. Phrynodema, Bitot's spots, night-blindness, and xerophthalmia, often described in connexion with vitamin-A deficiency, occur in other members of the same population, but have not been observed in kwashiorkor, nor does the liability to skin infections appear to be increased.³⁻¹⁰

Vitamin-A and -B deficiency of Sierra Leone has in common with kwashiorkor stomatitis, conjunctivitis, and skin lesions, but it occurs in adults; many cases show eversion of the eyelids, and the desquamation is relatively slight.^{11, 12}

Vitamin-B deficiencies.—The differential diagnosis from beri-beri, which also causes oedema and affects children and infants, is that beri-beri, unlike kwashiorkor, may lead to sudden death in infants; may be very acute in onset; causes polyneuritis; and produces no skin lesions.¹³ Moreover beri-beri responds to treatment in hours instead of in weeks.

Vitamin-B₂ deficiency differs from kwashiorkor in that the diet leading to the condition contains

FIG. 2.—Dark thickened patches of skin on the legs and buttocks of the same child.

no milk or yeast, whereas the diet of the children described above usually includes milk, though its quality is probably defective; and arkasa and kenki do contain yeasts, which have not, however, yet been cultured or tested for biological value.^{14 15}

Other deficiencies.—Kwashiorkor cannot be due to deficiency of vitamin C or vitamin D, because the victims show no evidence of either scurvy or rickets. No tests for mineral or protein deficiencies have yet been made.

Pellagra has in common with kwashiorkor the occurrence of cedema, sores at corners of mouth and

FIG. 3.—Photomicrograph of the liver showing extreme fatty infiltration.

FIG. 4.—Photomicrograph of the skin.

eyes, skin lesions, irritability, and an association with maize diet and with diet poor in protein. The differences are set out below in tabular form.

Differences between Kwashiorkor and Pellagra

KWASHIORKOR	PELLAGRA ^{16, 17}
Affected skin black, rugose, and soft.	Affected skin rough, dry, and branny.
Extensor surfaces and points of irritation and pressure affected.	Face, neck, and area, and dorsum of hands and feet affected.
Skin not photosensitive.	Skin photosensitive.
Occurs in children under five years.	Rare in children.
Usual under two years.	Almost unknown under two years.
Reflexes unchanged.	Peripheral neuritis common.
Dementia not observed.	Dementia common.
Patients may be largely on a breast milk diet.	Very rare with milk diet.
Arkasa (preparation of maize) in diet contains yeasts.	Yeasts said to be curative.
Fatty infiltration of liver severe and constant.	Fatty infiltration of liver may be present, but is generally mild.
Never seen in adults.	Common in adults.
Common condition in the Gold Coast.	Never yet described in the Gold Coast.

It has been suggested that kwashiorkor is in fact pellagra,¹⁸ but the points of difference appear to be more numerous and more striking than the points of similarity. The series of cases seen in East Africa by Dr. R. U. Gillan present apparently many points of resemblance to those described above³¹ and a perfectly typical case of kwashiorkor has been described by Dr. Dyce Sharp in Cape Coast.³²

I am indebted to the director of medical and sanitary services for permission to publish this article.

SKELETAL REMAINS OF BISHOP JAMES KENNEDY

STRUCTURAL alterations at the University of St. Andrews in 1930 provided an opportunity for an almost complete anthropometric examination of the remains of Bishop James Kennedy, "the most eminent man in Scotland" in the first half of the fifteenth century. Kennedy was of royal descent, his mother being James I. of Scotland's elder sister, whose second husband was Sir James Kennedy. He took an active part in the development of St. Andrews University founded in A.D. 1411 under a Papal Bull, and was appointed one of the regents of the kingdom during the minority of James III. He was a great churchman and statesman, and was thought to have been the means of preserving the Stuart dynasty on the throne. In 1465 he was buried in St. Salvator's Chapel and when the tomb was opened in 1930 a massive casket of dark oak, engraved "Jacobi Kennedy" fell apart owing to dry rot, and the skeleton lay exposed. Prof. David Waterston was invited to examine the bones during the restoration of the tomb and describes his findings (*Trans. Roy. Soc. Edin.*, 1935, lviii., 75).

No evidence of senile changes were seen in the skull or jaws. The limb bones indicate a man 5 ft. 8 in. in height, whose shoulders had been broad with powerfully developed muscles. The areas of attachment of the pronator quadratus on the left ulna was better developed than on the right, the difference being due to a special movement such as fencing. That he was probably a horseman is indicated by an excessive bone formation on the medial surface of the femora. An old oblique fracture is apparent in the right clavicle caused by indirect violence and sustained within the last few years of his life; there is an excess of callus but the fragments are in a position creditable to the surgeon of the day. For some years before his death he had suffered from chronic ill-health; the thoracic vertebrae are the seat of ossifying spondylitis, the sixth to the twelfth being fused together owing probably to some chronic pulmonary affection; there are also signs of a slight arthritis of the hip-joints.

The endocranial cast shows exceptional development of the areas of Broca and Wernicke, which are

associated with the power of speech. The brain in general was large and highly developed and falls into the "brachycerebral" group. The form of the skull is distinctive, low and wide in the frontal region, and high and wide in the occipital. The face is long, cheek bones prominent, and the nose is high-bridged, these features being shown in drawings reproduced in Prof. Waterston's paper. In measurement and in general form the skull is characteristically Scottish.

RADIOPHOBIA

WHEN X rays were first discovered there was very natural enthusiasm for experiment on their application to diagnosis and treatment. Then came a period of growing caution inspired by accidents and unexpected sequelae; and now again there are signs of a bolder outlook. But if our attitude is nowadays changing the change has by no means gone far enough for Dr. Foveau de Courmelles who inveighs against alarmist teaching (*Jour. de méd. de Paris*, 1935, xli., 889). He has the temerity to ascribe the whole scare to the non-medical radiographer who, he declares, came into the radiological department like a wolf into the fold and raised agitating cries about mysterious effects due to radiations from a distance. De Courmelles does not actually deny the damaging potentialities of rays directly encountered from near at hand, but he says that a very real and new disease—radiophobia—has been created by those who believe in influences felt yards away and through walls and ceilings. He suggests satirically that it is time we all started worrying about the effects of wireless rays, cosmic rays, and many other radiations which are now known to surround us from sun, earth, and stars. Certainly every alienist knows that the introduction of X rays has been a godsend to the deluded and paranoid patient who wants to explain abnormal sensations to his own satisfaction. Nevertheless, whatever de Courmelles may say, most radiologists will continue to feel that their speciality is no place for the foolhardy or careless worker.

CLANDESTINE DRUG TRAFFIC

RECENT meetings of the Council and the Assembly of the League of Nations have made it clear that, in spite of the complicated organisation which has been set up, there is no decrease in the amount of the illicit traffic derived from clandestine manufacturing. This "very real menace to the world" it was resolved must be met by "an intensified international campaign." In the first place it was recognised that a universal application of the existing convention is indispensable to final success, and in the second place yet another convention is required which shall be directed to the suppression of illicit traffic. It is hoped that an international conference will be convened next year to consider a scheme, already in draft, which is intended "to coördinate the various forces, international and national, whose task it is to put an end to the illicit traffic." The lack of universality of international coöperation is shown by the fact that Soviet Russia, the Argentine, Paraguay, Saudi Arabia, and Ethiopia are not parties to any of the three Opium Conventions. The Limitation Convention of 1931 also lacks the adhesion of Albania, Denmark, Finland, Iceland, Latvia, Liechtenstein, Luxembourg, Yugoslavia, Bolivia, Liberia, and the Union of South Africa. In addition to the foregoing the Geneva Convention of 1925 has not been ratified by China, Iran, the United States, Guatemala, Haiti, Mexico, Nicaragua, Panama, Peru, and Afghanistan. Even some Governments which are parties to some of the conventions are lax in effectuating them or, as in the case of a majority of the Latin-American countries, fail to supply annual reports to the secretariat of the League.

In May, 1933, at its seventy-third session the Council of the League instructed the secretariat to communicate to governments, for a first consultation,

draft articles prepared by the advisory committee as suitable for inclusion in an international convention. The replies which have been received were utilised for preparing an annotated draft for second consultation of the governments concerned. Out of 45 governments which have submitted observations 33 are in favour of the draft convention. The matter, after examination by a committee of experts, will again be brought before the Council.

There remains the not less important question, which has been for some years now before the advisory committee—namely, the limitation of production of raw opium and the coca leaf. It is now recognised that "clandestine manufacture depends on the liberal supply of raw materials" and that such limitation "if effectively applied would be a valuable step towards the final suppression of illicit traffic and drug addiction."

BRITISH AMBULANCE SERVICE IN ETHIOPIA

THE first unit of this service, consisting of four doctors, five orderlies, and transport personnel, will sail under the auspices of the British Red Cross Society next Saturday, Nov. 16th, by the *Sudan* and the *Rampura* for Berbera, where it will be joined by 24 trained African dressers recruited from Kenya and Uganda. This unit will proceed to the Ogaden war zone. Its members are Mr. John Melly, F.R.C.S. Edin. (principal medical officer), Dr. Arne Barkhuus, Dr. C. E. Bevan, and Dr. J. W. S. Macfie. A few days later the British Red Cross Society will send a small unit of two doctors and transport officers with medical stores via the Sudan to the northern war zone, which is at present entirely without medical aid. This second unit is being sent at the express request of the Emperor, and will be reinforced later. The appeals for funds for Red Cross help for Abyssinia have met with an immediate response, and the donations amount to about £22,000. But a total of at least £35,000 is needed and lack of money has prevented the equipment of the present unit with the X ray apparatus considered necessary. Further contributions, therefore, are urgently required, and they may be sent to Sir Arthur Stanley, British Red Cross Society, 14, Grosvenor-crescent, London, S.W.1.

GALL-STONE OBSTRUCTION IN THE INTESTINE

THE way in which an obstructing gall-stone has entered the lumen of the bowel must often remain doubtful, for it is usually considered wise to restrict exploration, and not to examine too carefully the gall-bladder and its surroundings. Rarely an opportunity arises of examining a case which throws light on the process of fistula-formation between biliary and intestinal tracts. In the October issue of the *British Journal of Surgery* Mr. C. P. G. Wakeley and Mr. F. W. Willway describe the findings of an autopsy in which a gall-stone measuring $\frac{3}{4}$ in. by $\frac{1}{2}$ in.—i.e., of a size which they consider might cause intestinal obstruction—was on the point of ulcerating through from the common bile-duct to the duodenum. The stone was tightly impacted in the ampulla of Vater and the ulceration was beginning just above the opening on the papilla. Passage through the papilla itself of a stone large enough to cause intestinal obstruction would seem to be impossible, and it is probable that the most usual method of entry into the duodenum is through a fistula between the fundus of the gall-bladder and the duodenum. Wakeley and Willway point out that there is a good chance that such a fistulous opening does not close completely afterwards, and that it is therefore dangerous to perform cholecystectomy on a patient who has recovered from gall-stone obstruction of the intestine. They also think it important that the surgeon operating on a case of obstruction by gall-stone should be alert to the possibility of double obstruction. They have examined stones which have appeared to be on the point of breaking into two; they actually met

with a case of double obstruction, one stone being lodged in the rectum, and the other in the ileum. The two stones fitted neatly together. A facet on a stone removed should at once raise the question in the surgeon's mind as to whether another stone is present. The site of impaction seems to be fairly constantly in the ileum, most often in the lower ileum. Wakeley and Willway found the stone in the lower ileum in 7 cases, and in the middle ileum in 2 cases, while the site was in other parts of the intestine in four instances only. All their 11 patients (one with double obstruction) were operated on, with the low mortality figure of 3 deaths out of 11 cases. A correct preoperative diagnosis was made in 2 cases only. The possibility of dislodging the stone, and of shifting it either up or down to a healthier site for removal, is discussed. They found dislodgement possible in 6 cases; in 2 they were able to push the stone on, and in 4 they pushed it back. It was then possible to open the bowel at a part where healing could be confidently expected.

THE VICTIMS OF X RAYS

THE year 1935 is the fortieth anniversary of the discovery of X rays, and a notice in the November issue of the *British Journal of Radiology* states that it is proposed to publish in *Strahlentherapie* a memorial to all the X ray workers who have died as a result of devotion to their calling. Radiologists who have been personally associated with these men and women are asked to send brief accounts of their lives and deaths (about two type-written pages) and a photograph to the editor of *Strahlentherapie*, Prof. Hans Meyer, Parkallee 73, Bremen, Germany.

Oswestry, Robert Jones and Agnes Hunt Orthopaedic Hospital.—

Res. Surg. O. £350.

Plumouth, Prince of Wales's Hospital, Greenbank-road.—H.S.

At rate of £120.

Poplar Hospital for Accidents, East India Dock-road, E.—

Second Res. O. £175.

Preston, Biddulph Grange Orthopaedic Hospital.—Jun. H.S. At

rate of £150.

Princess Elizabeth of York Hospital for Children, Shadwell, E.—

Res. M.O. £200. H.S. Also Cas. O. Each at rate of

£125.

Princess Louise Kensington Hospital for Children, St. Quintin-

avenue, W.—Clin. Asst. for Out-patients.

Queen Mary's Hospital for the East End, Stratford.—Res. M.O.

and 2 Cas. and Out-patient Officers. Each at rate of

£150. Also 2 H.S.'s, H.P., Obstet. H.S., also Res. Anæ-

sthetist and H.P. Each at rate of £120.

Rochester, St. Bartholomew's Hospital.—Res. Surg. O. At rate

of £225.

Royal Waterloo Hospital for Children and Women, Waterloo-

road, S.E.—H.S. At rate of £100. Also Hon. Clin. Asst.

St. Charles's Hospital, St. Charles-square, W.—Asst. M.O. £250.

St. George-in-the-East Hospital, Raine-street, E.—Asst. M.O.

£250.

St. Olave's Hospital, Lower-road, Rotherhithe, S.E.—Asst. M.O.

£250.

Salford, Infectious Diseases Hospital.—Jun. Asst. Res. M.O.

£200.

Salisbury General Infirmary.—Res. M.O. £250.

Salvation Army, Mothers' Hospital, Lower Clapton-road, E.—

Sen. Res. M.O. £150. Also Jun. Res. M.O. At rate

of £80.

Sheffield Royal Hospital.—Clin. Asst. to Ophth. Dept. £300.

Southampton, Royal South Hants and Southampton Hospital.—

Cas. O. Also H.S. to E.N.T. Dept. and Res. Anæ-

sthetist. Each at rate of £150.

South London Hospital for Women, Clapham Common, S.W.—

H.P. and two H.S.'s. Each at rate of £100. Also Anæ-

sthetist. 10s. 6d. per attendance.

Stafford, Standon Hall Orthopaedic Hospital.—H.S. £200.

Swansea General and Eye Hospital.—Res. Anæsthetist. £150.

Taigarth, Breconshire Mid-Wales Counties Mental Hospital.—

Asst. M.O. £400.

Watford and District Peace Memorial Hospital.—H.S. and H.P.

Each £150.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Jun.

Res. H.S. At rate of £100.

West London Hospital, Hammersmith-road, W.—Physician to

X Ray (Therapeutic) and Electrical Depts.

Winchester, Royal Hampshire County Hospital.—H.S. At rate

of £125.

Wokingham, Berks. Pinewood Sanatorium.—Asst. M.O. £250.

York County Hospital.—H.P. £150.

The Chief Inspector of Factories announces vacancies for
Certifying Factory Surgeons at Biggleswade (Bedford) and
Rochford (Essex).

NEW MATERNITY CLINIC AT DEPTFORD.—The
foundation-stone of a new maternity clinic at Dept-
ford, which it is hoped will centralise six of the
eight existing clinics, has been laid by the mayor. The
building will be in two blocks, with a sun balcony, a
gymnasium for massage and remedial exercises, and a
toddlers' playground.

ADDRESSES AND ORIGINAL ARTICLES

INTEGRATION OF THE ENDOCRINE SYSTEM*

By SIR WALTER LANGDON-BROWN, M.D. Camb.,
F.R.C.P. Lond.

EMERITUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF
CAMBRIDGE, AND CONSULTING PHYSICIAN TO
ST. BARTHOLOMEW'S HOSPITAL

IN 1894 Horsley was awarded a medal by the Royal Society "for his investigations relating to the physiology of the nervous system, and of the thyroid gland." These were, of course, two separate lines of inquiry, but my purpose to-day is to show how much more closely these two subjects are related than was imagined at that time.

Recent Lines of Advance

Three recent lines of advance are leading to a clearer conception of the integration of the endocrine system.

1. The diencephalon (particularly the part we were taught to call the hypothalamus) has been conclusively shown to be the nervous structure concerned with the expression of the emotions.

2. The pituitary, which is so closely associated with the diencephalon, has become recognised as the leader of the endocrine orchestra.

3. It is now realised that all nervous impulses have a chemical mediator between the neuron and the tissue cell, and indeed between one neuron and another.

DIENTEPHALON AND THE EXPRESSION OF THE EMOTIONS

From the experiments of Sherrington it has been known that if the higher parts of the brain be severed from the diencephalon in a dog, the animal responds to ordinary stimuli in an exaggerated way by an explosion of what he terms "sham rage." Cushing has reported similar explosions in a patient suffering from a cerebral tumour which similarly destroyed these connexions. The ravages of lethargic encephalitis on this part of the brain have not only damaged the statics of the body but have profoundly affected the temperament and behaviour of the victim.

In these instances we are dealing with partial lesions which no doubt have an irritative effect on the remainder. But in an extraordinary case under the care of Prof. Naish,¹ of Sheffield, a teratoma involving the whole of hypothalamus completely blotted out the normal expression of the emotions; in Hughlings Jackson's nomenclature, a destroying rather than a discharging lesion.

A girl, aged 10, came under observation with the history of having been of an unusual temperament since birth. As an infant she used to sleep considerably longer hours than do most infants, and without moving. As she grew older it was noticed that she never showed joy, excitement, or fear, although she apparently felt fear, especially of loud noises, darkness, solitude, and certain persons. She would say she was afraid, but her expression and voice were calm. What was taken to be anger was shown by sudden refusal to comply with suggestions. She appeared to have strong feelings, but displayed none of the usual childish graces; her manners to chance callers were incorrigibly rude and she was very impenetrable

to suggestion. All her life she was liable to sudden rises of temperature followed shortly by sudden falls. Her mental powers were good and she had an excellent memory. Her balance was never very good; when she tripped she seemed to have less than the usual powers of recovery and would fall flat on the floor. Three years before her death it was noticed that she was drinking heavily and passing large quantities of pale urine by day and by night; her appetite for solid food was poor and she was wasting, and not growing at all. The polyuria continued till about five weeks before death and then ceased somewhat abruptly. There was no sugar in the urine. Her emotional reactions were further diminished; she never shed a tear. Some three or four weeks before her death she found herself unable to walk, surmised that she was going to die, and said in an indifferent tone "Well, we can't help it." She appeared to feel the cold intensely, and was apt to huddle in front of a big fire. This feeling of cold increased until some two or three weeks before death when it ceased abruptly. She began to fall asleep in unusual places. Her powers of vision were lost apparently quite rapidly about five weeks before her death.

On admission she was remarkably drowsy. The pupils were equal and reacted normally. No cranial nerve paralysis was found; the reflexes were normal. There was marked pallor of the central area of each optic disc. She became comatose and died a few days later.

At the post-mortem a firm tumour with a smooth lobulated surface was found projecting from the base of the brain in the hypothalamic region behind the optic chiasma. The body showed no other abnormality except for enlargement of the mesenteric glands with evidence of tuberculous infection. The pituitary gland appeared to be normal. Microscopically the tumour was a teratoma.

You will note that she had temporary symptoms presumably due to pituitary compression, such as polyuria, disturbances of temperature, and much drowsiness, but that the most striking feature was the blotting out of nearly all normal emotional expression.

My second point really contains two separate propositions.

ASSOCIATION BETWEEN THE DIENTEPHALON AND PITUITARY

The anatomist of the past, looking at the brain enclosed in bone, and joined by a narrow stalk to this small pituitary body also thus enclosed, like a brain in miniature, were struck with the idea of a little shrunken brain, which, as it were, responded to, or repeated, the actions of the big brain above. Modern research has shown that there is more in this idea than was supposed in the nineteenth century. Harvey Cushing gave a brilliant review in his Lister memorial lecture² of the relationship between this gland and the diencephalon lying immediately above it; he re-echoed the saying of Ridley in 1693 that "it seems in a manner almost impossible to treat of one independently of the other."

A clear-cut instance of inhibition of the secretion of pituitrin through emotional disturbance is provided by Leslie Pugh's observation on cows that refuse to yield their milk, either because the calf has been taken away or because they object to an individual dairyman. If she hears the blaring of the calf the mother may yield her milk, but either cause of her refusal can be overcome by an injection of pituitrin. The disturbance of her diencephalon inhibited the chemical stimulus to the expulsion of milk, but the injection of that stimulant cut under the nervous inhibition, and the milk had perforce to flow.

* Being the fifth Horsley memorial lecture (abbreviated), delivered at University College, London, on Nov. 19th, 1935. The full text of the lecture will be published later by the Cambridge University Press.

Diabetes insipidus has been referred by some observers to a hypothalamic lesion and by others to a pituitary one. It is generally admitted now that damage to either place or the stalk connecting them can have this effect. Since pitressin can reduce the secretion of water by a denervated kidney, it is clear that when a nerve lesion leads to polyuria it does so by interfering with the secretion of pitressin. Presumably nervous polyuria is a temporary functional condition of the same sort. Thus we may accept the view of a diencephalo-pituitary apparatus, in which the nervous apparatus can implement itself through the chemical secretions of the glandular portion. Moreover, as P. T. Herring has pointed out, this secretion may be diverted either into the hypothalamus or into the general circulation by a local vascular adjustment.

THE PITUITARY AS LEADER OF THE ENDOCRINE ORCHESTRA

Cushing some years ago laid down the principle that polyglandular syndromes had their primary focus in some pituitary disturbance. The close association between the pituitary and the other endocrine glands is now generally admitted. Facts have accumulated so rapidly, that in order to gain any clear impression of the present position it is necessary to be concise and rather dogmatic. We recognise three types of cell in the anterior pituitary: (1) the chromophobe which resists staining and is probably the parent cell of (2) the eosinophil, and (3) the basophil. An adenoma composed of chromophobe cells diminishes pituitary function. Fröhlich's syndrome of obesity of the limb-girdle type and genital hypoplasia was originally recognised in a case of this sort. But extreme obesity may also result merely from division of the pituitary stalk, either experimentally or by disease. Milder cases, occurring in the absence of an adenoma, may be attributed to a delay in the differentiation of chromophobe cells; puberty may be delayed but the outlook is not so serious. That the eosinophil cells are the source of a growth hormone can be definitely accepted. The experimental evidence as to the production of gigantism in rats, the clinical evidence derived from acromegaly and acromiery, and from Simmonds's disease both in children and in adults seem alike satisfactory, though Novak³ maintains that this hormone has not yet been obtained free from all the others. The basophil cells became regarded as the source of the sex hormone after the researches of Evans and Simpson, and still more so after Cushing's description of the syndrome of pituitary basophilism.⁴ We may accept the view that the growth and sex hormones are antagonistic, and that it is not until the latter gains the upper hand that puberty occurs, but as I hope to show later, there are strong reasons to doubt the basophil cells as the source of the sex hormone. The position with regard to gonadotropic hormones is involved. We must distinguish clearly between oestrogenic substances which can act directly in the absence of the ovaries and gonadotropic principles which act indirectly by exciting the production of oestrin in the ovary. The gonadotropic extracts in therapeutic use are obtained not from the pituitary but from the placenta or from pregnancy urine; their active principle is probably chorionic in origin. Although it is similar to, if not identical with the type which can be obtained by chemical treatment of the pituitary, there is an important difference in their physiological action. The one obtained from the pituitary can produce both maturation of the ovarian follicles and their subsequent

luteinisation in an animal deprived of its own pituitary, while the chorionic one cannot do either under such conditions (Collip⁵). The contrast between the small amount of oestrogenic substance produced by the pituitary and the enormous amount of oestrin found in the placenta, whence it overflows freely into the urine during pregnancy, is highly suggestive of a catalytic agent acting on a large mass of substrate, or at any rate of a stimulating synergic mechanism. In other words, while we must admit the prime importance of the anterior pituitary in initiating the events of the reproductive cycle, the process suggests that it does so by calling into activity hormones formed in the gonadal apparatus itself. This seems all the more probable in view of its capacity to evoke a response in male and female alike. More surprising is the fact that though the primary sex hormones are not identical, even though chemically closely related, descent of the testes in cryptorchids has been repeatedly observed after the injection of the extract from pregnancy urine.

It is still a matter of dispute whether the maturation and the luteinisation of an ovarian follicle are excited by two distinct hormones from the anterior pituitary or by only one, which produces these two effects according to the stage of the cycle. Most observers now, except Collip, seem to incline to the latter view, which would harmonise with the general conception I am advancing.

After the recognition of the growth and sex hormones, claims for other hormones secreted by the anterior pituitary multiplied rapidly. The principal ones are as follows:—

The thyrotropic hormone.—The loss of the secretion of the anterior pituitary through disease or experimental extirpation is followed by atrophy of the thyroid with reduction of the basal metabolic rate, and these changes can be prevented by injection of an anterior pituitary extract. Such an extract can produce hyperplasia of the thyroid with exophthalmos and an increased basal metabolic rate, but the two last named cannot be produced in animals from which the thyroid has been removed.⁶ We have here an experimental method of producing Graves's disease and as in Graves's disease the condition can be controlled by the administration of iodine. Such observations throw light on the emotional causation of hyperthyroidism. It has long been known that the thyroid has an abundant supply of sympathetic nerves, but as these appear to be purely vasomotor, and indeed vasoconstrictor in action, it was difficult to see how their stimulation could lead to thyroid hypertrophy. It is therefore tempting to attribute such enlargement to excessive production of the thyrotropic hormone in the pituitary under diencephalic stimulation. Harington, however, thinks that although the greatly increased rate of secretion by the gland in hyperthyroidism is probably due to some extrinsic stimulus and although the thyrotropic hormone has been shown to be such a potential cause, it is unlikely that anything so simple as the overproduction of this hormone can account for Graves's disease.

Parathyrotropic hormone.—The existence of this hormone has not yet been established, but the striking similarity of the decalcification and bone pains of pituitary basophilism and of hyperparathyroidism is suggestive, despite the fact that in the former the blood calcium is not increased as in the latter.

Diabetogenic hormone.—Houssay first found that if a dog is previously deprived of its pituitary, subsequent removal of its pancreas does not cause glycosuria. But if an anterior pituitary extract is injected the blood-sugar is raised and sugar appears in the urine. Houssay has recently obtained this blood-sugar raising principle from the urine and according to Wilder and Wilbur it acts by way of the adrenals on the liver. In this connexion it is of great interest that Hertz⁷ found symptoms of von Gierke's disease in a pituitary dwarf, suggesting that the

non-utilisation of glycogen characteristic of that condition is due to a lack of Houssay's pituitary hormone. We are now realising the complexity of the endocrine-autonomic mechanism by which the blood-sugar level is maintained; a balance being struck between the agencies tending to depress it—i.e., the pancreas under the influence of the vagus, and those tending to raise it, i.e., both lobes of the pituitary, the thyroid and the adrenals acting with the sympathetic, while mid-brain and bulbar centres regulate the whole. Just as cerebral anaemia leads to a rise of blood pressure through peripheral vasoconstriction, and as increased hydrogen-ion concentration in the medulla leads to increased respiratory effort, so a fall of blood-sugar brings into play the mechanisms which raise it again. Conversely the intravenous injection of hypertonic glucose may so stimulate the other side of the balance that actual hypoglycaemia may follow.

The fact that this Houssay hormone acts much more rapidly if injected into the cerebro-spinal fluid is regarded by Lucke as evidence that it acts through the nervous centres and then presumably via the splanchnics on the adrenals. This is not unlike the view expressed by J. J. R. Macleod in the Herter lectures shortly before his death. Funk and others noting the marked ketonuria which occurs both with Houssay's extract and in von Gierke's disease claim to have isolated a separate *ketogenic principle*, differing from that which raises blood-sugar because it increases the lipid content of the blood.

Lactogenic hormone.—It has long been recognised that the post-pituitary can influence the expulsion of milk from the mammary ducts, but it is now claimed that an anterior pituitary hormone, prolactin, stimulates the actual secretion, while oestrin is responsible for the unfolding of the mammary duct system.⁵

Adrenotropic hormone.—Here we are on rather securer ground. The close resemblance between pituitary and adrenal virilism, the fact that progeria was first referred to adrenal atrophy and now to atrophy of the pituitary, the association of anencephaly with incomplete development of the adrenals all point to some fairly close interaction. Experimentally injection of anterior pituitary extracts can produce marked adrenal hypertrophy. Among others, Broster and Vines and Lescher and Robb-Smith⁹ have emphasised the great difficulty of determining whether in a case of virilism the primary lesion is in the pituitary or the adrenal. Indeed in proved cases of a pituitary basophil adenoma such as Parkes Weber's the adrenals showed hypertrophy.

THE RÔLE OF THE BASOPHIL CELLS

We are now in a position to come to closer grips with the questions—what is the function of the basophil cells and can we draw any conclusions therefrom which will throw light on the way in which the pituitary does its work? We were a little too ready to conclude that the syndrome of pituitary basophilism confirmed the idea that the sex hormone originated in the basophil cells. Woollard¹⁰ was the first, as far as I am aware, to point out that if this were so, it would be unreasonable to suppose that in women virilism and decay of sexual function should follow excess of it. Injection of pituitary gonadotropic hormone produces nothing like pituitary basophilism, but may produce gonadal atrophy. Woollard envisages the basophil cells as the inhibitors of the acidophilic activities rather than as the source of the sex-hormone. He thinks that the pituitary plays no part in sexual differentiation, but brings testis or ovary to structural differentiation and full endocrine activity. Lescher and Robb-Smith come to a similar conclusion, that the basophil cells are the source of some depressive inhibitory substance. Levy Simpson¹¹ also suggests that the basophil secretion is inhibitory on the homosexual glands, allowing the development of a latent heterosexual rudiment. Wright has reported an excess of the pituitary sex hormone in the urine of female patients with basophilism; Levy Simpson thinks it is the

male sex hormone that is present. In any case clinical evidence of increased sexual activity in such patients is more than dubious.

Crooke¹² has described a characteristic hyaline change in the basophil cells in Cushing's syndrome, whether that syndrome be associated with basophilic adenoma or a neoplasm of the thymus or hyperplasia or a neoplasm of the adrenal cortex. He did not regard this as a degenerative change, but as an expression of altered physiological activity. In Addison's disease Crooke and Russell¹³ found an extreme reduction in the pituitary basophil cells. They think this may be the cause of the low blood pressure and possibly of the hypoglycaemia; it is certainly in sharp contrast with the high pressure and hyperglycaemia found with basophilic adenomas. These authors, together with Evans,¹⁴ have described two cases of such adenomas in which most of the characteristic symptoms of the syndrome were lacking, cardiovascular hypertrophy being the salient feature. Nevertheless, they are not prepared to go as far as Cushing in regarding essential hypertension as due to increase in the number of basophil cells. Broster and Vines regard an excess of fuchsin-staining material as the essential change in the adrenal cortical cells which produces virilism. This change may be absent in pituitary basophilism. The way in which a growth in the thymus gland, usually regarded as antagonistic to sexual development, may stimulate the basophilic syndrome adds to all these doubts concerning the sexual functions of the basophil cells.

In earlier days the number of "centres" located by the physiologist in the medulla around the fourth ventricle multiplied until they produced a revolt against the whole conception. That centres should exist ready-made for a contingency which might never arise throughout life was a *reductio ad absurdum*. In the same way the functions controlled by the anterior pituitary have multiplied until the existence of a separate hormone for each function has become almost incredible. It seems more probable that the somewhat violent chemical measures adopted to isolate these pituitary hormones even in only an approximately pure state have produced alterations in the basic products, as P. E. Smith⁸ suggests. In the less complicated case of the thyroid Harington¹⁵ believes that the molecule of the complete active secretion contains both thyroxine and diiodotyrosine, and that some linkage between them is ruptured during the hydrolysis necessary for the isolation of thyroxine. Surely something of the same sort is probable in the case of the pituitary. Thus its thyrotropic hormone is obtained by acid extraction, which may easily produce changes in chemical structure.

In view of these facts, this newer conception of the anterior pituitary producing an accelerating hormone in the eosinophil cells and an inhibitory one in the basophil cells seems a rational one—the functions and the staining reactions of these cells being alike diametrically opposed. One may regard the anterior pituitary as largely controlled by the diencephalon and putting down the loud or soft pedal, as it were, on the other glands.

Fresh light on the whole subject has been thrown by Dodds¹⁶ who classifies hormones under two headings. The first are complex protein bodies formed by the anterior pituitary, which act on the other endocrine glands, causing them to form the secondary type of hormones which are bodies of comparatively small molecular weight, most of which have been isolated in a crystalline form and some of

which have actually been prepared synthetically. It will be noted that in this respect the posterior pituitary belongs to the second group.

In conjunction with Cook, Dodds has carried out a brilliant series of researches into these secondary hormones and has shown that simpler compounds than those prepared by the body can have the same biological effect to a less or even greater extent. This basal group with the simplest chemical structure that can produce the biological effect he calls the "skeleton key" which picks the physiological lock. Even more striking was his demonstration that the same basal group could produce more than one biological effect. To such groups he gave the name of "pass keys." Perhaps the most impressive instance of this is the condensation of benzene rings into a phenanthrene ring, which by simple alteration in the degree of hydrogenation can give rise to œstrin, to vitamin D or calciferol, and to the carcinogenetic substance present in coal tar.

It is accordingly by no means fanciful to regard the anterior pituitary as receiving the impulses from the diencephalon, and producing an activating and an inhibitory hormone of a protein character according to demand, which can speed up or inhibit the secretion of the simpler grade of hormone in the other endocrine glands. At any rate it is a unifying hypothesis which deserves further and careful consideration.

ANTIHORMONES

The question has not been simplified by the claims made for the existence of antihormones. Collip showed some time ago that parathormone gradually lost its effect on repeated injections. One might imagine that this failure could be adequately accounted for by its destructive action on the calcium content of bone and muscle, but he¹⁷ now thinks that there is an antihormone both to the pituitary growth and the thyrotropic hormones, and advances the hypothesis that the production of antihormones may be responsible for hypoglandular states. He regards a hormone-antihormone linkage as the normal condition, which can readily be disturbed. The purposive character of such antihormones is hard to see; certainly thyroid administration is effective when continued over many years. The claim for the existence of a catechin in the blood which is antagonistic to thyroxine, if substantiated, suggests a simpler explanation—namely, that various chemical substances can destroy hormones, just as we know the acetylcholine and adrenaline set free on nerve stimulation are rapidly destroyed in the blood or tissue cells.

A CHEMICAL MEDIATOR BETWEEN NEURON AND TISSUE CELL

And this leads me directly to my third point. It has long been common knowledge that emotional states may modify secretion; the tears of sorrow and the dry mouth of fear are proverbial. In such instances it is obvious that a nervous impulse has produced or prevented a chemical process. But it is only quite recently that we have realised that all nervous impulses have a chemical mediator between the neuron and the tissue cell, and indeed between one neuron and another. In Hopkins's phrase, chemical substances are produced which translate for the tissues the messages received by nerves. We have indeed been curiously blind to the fact that the chemical changes produced in a gland by nervous stimulation is only a special case of a general law. I say curiously blind, because this century had only just begun when Langley found a clue which was not really followed up for years. We knew that adrenaline

is manufactured by the cells of the adrenal medulla, which are actually formed out of sympathetic ganglion cells. Langley enunciated the law that the effect of adrenaline on any part is the same as if the sympathetic nerves to that part were stimulated; an extraordinarily interesting example of a chemical substance imitating a nervous response. The adrenal medulla was seen to represent the post-ganglionic element in the sympathetic. In 1907 W. E. Dixon made some tentative experiments on the liberation of a chemical substance in the heart after vagus stimulation; unfortunately this encountered so much scepticism that he dropped the subject. But later the work of Loewi and of Dale has proved that acetylcholine is liberated at the terminals whenever sympathetic or parasympathetic pre-ganglionic fibres are stimulated, and adrenaline at the sympathetic post-ganglionic terminals. So Dale¹⁸ speaks of cholinergic and adrenergic fibres, and incidentally shows how this conception explains Langley and Anderson's cross-suturing experiments. You can cross suture cholinergic with cholinergic or adrenergic with adrenergic, but you cannot successfully cross suture cholinergic with adrenergic fibres. Cannon thinks that the substance liberated at the sympathetic post-ganglionic terminal is not identical with adrenaline; he thinks he can extract a slightly different one after an excitant action from that appearing after an inhibitory one. But is it not possible that the adrenaline is modified by an ergotoxin-like action in the former case? For Loewi has shown that physostigmine imitates or increases the effect of parasympathetic stimulation because it prevents the blood or the tissue cell from destroying the acetylcholine produced. Just as physostigmine facilitates, so does atropine interfere with the normal chemical results of parasympathetic stimulation. It is important to note that just as much acetylcholine is produced, whether atropine is given or not—the atropine merely blocks access to the tissue cell.

A Receptor Substance between Nerve-ending and Tissue

This leads me to an aspect of endocrinology which is urgently demanding attention. Some thirty years ago Langley and Elliott independently postulated the existence of a receptive substance between the nerve-ending and the tissue as necessary to explain the facts then known. If such a postulate was required then, how much more is it needed to-day. Just as the appropriate chemical material may get into this receptive substance so may a toxin. G. N. Myers has shown that a therapeutic drug may seize on the receptive substance and thus bar the way to the ingress of the toxin. It seems to me that the pharmacology of the future will have to concern itself with the natural history of these receptive substances, and find out in what way they can be helped by drugs both positively, by facilitating their reactions, and negatively, by blocking the way against the entrance of toxins. Nor is this topic remote from my subject, for Zondek maintains that the adsorption of a hormone such as thyroxine is decreased in the presence of narcotics, such as the barbiturates which are able to adhere to the cell surface and thus to displace the hormone from it. But it is also germane to my subject in a wider sense. Sir Henry Dale, in his recent Harveian Oration before the Royal College of Physicians,¹⁹ reminded us that we are still entirely without any conception why a particular cell should be sensitive to a particular

chemical substance or why the same substance should augment the activity of one type of cell and inhibit that of another. He indicates indeed precisely the problem to which many minds are beginning to devote themselves—the nature of these receptive substances. The nature of the stimulus has been intensively studied, but it is now clear that this is only half, and perhaps the simpler half of the question. The importance of the responsive capacity of the receptor tissues was clearly indicated by Harrison in his Harvey Lectures for 1934. He showed that when transplantation is effected between embryos of species of different sizes, the transplant responds according to its inherited growth capacity rather than to its new endocrine environment. As Keith pointed out some years ago, the partial gigantisms in certain cases of hyperpituitarism can only be explained on the theory that the locally hypertrophied tissues had developed a special sensitiveness to the growth hormone. H. M. Evans has recently shown that the response of the dachshund and of the sheep dog to injections of the pituitary growth hormone is entirely different. Indeed, if such things were not so it would be difficult to account for the structural plasticity of the dog in the hands of the breeder.

Again, after the menopause oestrin may be present in large amounts yet reproductive cycles cease, as if the reproductive organs had lost their capacity to respond rather than that the hormonal stimulus had failed.²⁰ According to Zondek the fact that hormones in such minute quantities can produce marked generalised effects indicates that they act as catalysts; their activity seems apparently to depend upon the integrity of cellular structure; they are *physical* catalysts. He maintains that the hormones circulate in the blood in an active form; not until they reach the organ of their destination, where they are adsorbed, do they become activated. But at present we have no inkling as to the mechanisms by which any such cellular response is produced or rendered specific. Hopkins,²¹ commenting on the comparative failure of the attempts to correlate chemical structure with pharmacological action, pointed out that so far the investigation had been one-sided and should involve consideration of the structure of the cell. The same comment is applicable to the present position of endocrinology.

For a time after Starling developed his conception of the chemical control of the body by hormones, the pendulum swung so far in that direction that it seemed as if the nervous system would be deprived of its pride of place, although Starling himself had pointed out that its special function was to provide for special rapidity of response when required. There are a good many examples of a double mechanism in physiology, and it might be expected to occur in the endocrine system. Cannon's theory of the emergency action of adrenaline in coming to the assistance of the defensive apparatus of the sympathetic is a good example, which, though seriously criticised by Stewart and Rogoff, seems to have re-established itself in favour. Indeed, Dale's work makes it all the more intelligible and probable. Then the nervous control over the pancreatic secretions, both external and internal, became recognised in addition to chemical methods of stimulation such as secretin. If the recent claims²² are substantiated, that the oral administration of a duodenal extract can keep the blood-sugar of a diabetic normal after he has first been treated by insulin, not only will this double mechanism have been proved for the internal secretion of the pancreas but a therapeutic advance of import-

ance will have been made. And so the pendulum is swinging back again. But lest it should be thought that the propositions, with which I started, stressed the nervous control too much, I will try to restore the balance by referring to recent work on the organiser in the embryo.

The Organiser in the Embryo

We have realised for years that lowly organisms react to such stimuli as light and chemical agents at an evolutionary level before a central nervous system has appeared. But recent embryological work has shown the profound influence exerted by chemical agents on the very genesis of the nervous system. Some twelve years ago Spéman showed that if he transplanted a group of cells from the dorsal lip of the blastopore—i.e., the part where a central nervous system would first appear in the development, to some other part of an embryo—it would lead to the initiation of a central nervous system there, however different the situation was from the normal one. He could produce two central nervous systems at right angles to each other. He called these cells the organiser. Recently the Needhams and Waddington²³ at Cambridge have shown that they can reproduce all the effects of the organiser by extracting a chemical substance from these cells which resists both freezing and boiling. It is therefore a very definite chemical entity but not a ferment. Thus from the very start chemical and nervous mechanisms are interdependent. They have now gone on to some most exciting observations. They have been able to imitate this chemical organiser synthetically and it appears to be closely allied to, if not identical with, oestrin which we know to be a sterol. Thus the ovarian hormone is apparently carried on to the next generation and is primarily responsible for organising the central nervous system. These observers have also been able in a similar way to lead to the formation of various mesodermal structures in parts of the body to which they are foreign.

It seems to me probable that the formation of teratomata is to be explained by the escape of such chemical organisers from their proper site. Dr. Needham has called my attention to some observations by Witschi²⁴ on the results of delaying the fertilisation of amphibian ova. If the sperm cell is not allowed to unite with the egg cell almost at once, there is a disturbance of the normal sex-ratio in the offspring. If there is a further delay the organiser is liberated at the wrong time and place and teratomata result. Finally, if there is a still greater delay exceedingly abnormal monsters result which actually produce metastases when implanted into adult amphibia. Holtfreter in Munich has already applied these results to the explanation of teratomata in human beings.

It would be a valuable piece of gynaecological research to see if the occurrence of maternal salpingitis or endometritis, which might well delay the fertilisation of the egg cell, could be correlated with the incidence of teratomata. But it would be difficult because a teratoma may produce no symptoms for years. However, Aschheim²⁵ states that the gonadotropic hormone of pregnancy is to be found in the urine of patients suffering from a teratoma, even in men! This may provide a diagnostic test of real value, and seems to make still more probable the association of teratomata with oestrin gone astray, as it were. Incidentally, I may suggest that the discovery of the importance of oestrin for the development of the embryo may explain why the

chorionic villi of the placenta should manufacture it in such large amounts. Hitherto I do not know that a reason has been offered for this striking fact.

Relation between Œstrin, Calciferol, and a Carcinogenetic Substance

That œstrin, calciferol, and the carcinogenetic substance in coal tar should all be closely related sterols is remarkable. It is extraordinary to find that the necessary stimuli to the growth of the next generation, to the ordinary growth of bone, and to the disorderly growth of malignant disease are due to closely similar chemical substances; that they should to some extent be interchangeable is even more extraordinary. The fact that teratomata stand halfway between abnormal twinning and malignancy is full of interest. It is true that some critics declare that to say that all these conditions are associated with alterations of sterol metabolism is no more than saying that another group of conditions are associated with altered protein metabolism, so manifold are the sterols. Loeb²⁶ is of opinion that though the hydrocarbons of tar and the œstrogenic hormones may be more efficient than other factors in producing cancer, in principle they do not act differently to numerous other conditions which may cause it. They seem able to induce the change at any point where they come into prolonged contact with tissues which still possess the potentiality of growth and proliferation. But I think such criticisms rather unnecessarily belittle a remarkable series of mutually consistent observations. The widespread importance of sterols in what one may call the metabolism of the moment, has received additional evidence from some recent researches of Carter and Mapson,²⁷ who find that for the proper functioning of both voluntary and cardiac muscle in the frog, a definite proportion between the concentrations of acetylcholine and sterols in the tissue is necessary. They find moreover that many of the sterols can replace each other in this as in their other actions. Further, they showed that if thyroxine is added to the Ringer's solution in which the muscle is bathed, a tetanic contraction instead of the normal single twitch results on electrical stimulation if this acetylcholine sterol balance is disturbed. Here are some hints as to the lines along which research may reveal something of the factors in the receptive mechanisms.

Sex Reversal

It may be well to say something on sex reversal in general. Undoubtedly the initial bias in sex differentiation is determined by the chromosomes. But although this is the sole and efficient cause in, for instance, insects, its effect is much slighter in birds and mammals, and has to be reinforced by the endocrine activity proper to each sex. Indeed, as Woollard²⁸ has pointed out, before this time is reached the influence of the chromosomes is so weak that the embryo passes through an indifferent or bisexual phase. This is followed by a brief interval when a masculinising tendency apparently occurs in both sexes; in the female it declares itself as a medullary mass in the rete of the ovary which is really a testicular rudiment, and which may later in life become the site of a virilising new growth. The gonadal territory in the embryo consists in the first instance of a ridge on the medial side of the mesonephric mass. It seems certain that sex reversal is caused by an abnormal growth of mesonephric derivatives which are normally present, though only

in a rudimentary form in the female. It follows that the testis is monosexual while the ovary is bisexual, with a male medulla and a female cortex, as it has been expressed. Therefore, physical sex reversal can only occur in woman, and may be due to—

1. Overaction of a basophilic adenoma which inhibits normal ovarian activity, allowing the rudimentary masculine elements to reassert themselves.

2. Overaction of the adrenal cortex, which is mesonephric and contains similar cells to those of the testis.

3. Overaction of mesonephric cells in the rete ovarii, which, as in some of the arrhenoblastomas first described by Pick,²⁹ may actually develop convoluted tubules resembling the seminiferous tubules of the testis.

Closely similar syndromes of virilism may originate in any one of these three positions and are all due to absolute or relative overaction of masculinising mesonephric structures. On the other hand, the testis being monosexual, sex reversal in man can only be psychogenic.

Conclusion

To state briefly the view of the integration of the endocrine system which I am attempting to visualise, there is doubtless an autonomous activity of these glands according to the steady biochemical demands of the body, but their activity can be profoundly modified and extensively controlled by centres in the diencephalon which are largely concerned with emotional expression. These centres may operate directly through the sympathetic nervous system (indeed, the hypothalamus has been called the head ganglion of the sympathetic) or indirectly through the chemical activities of the anterior pituitary. The anterior pituitary forms two basic secretions probably of a protein character, one being stimulating, the other inhibitory in effect. They correspond in fact to Sharpey-Schafer's original distinction between a hormone and a chalone. It is suggested that the former is produced by the eosinophil, the latter by the basophil cells. These basic secretions are capable of chemical modification according to the needs of the body, and are then ready to stimulate or restrain the secretion of simpler hormones by the other endocrine glands, including the post-pituitary. It may be, as Zondek³⁰ maintains, that the hormones circulate in an inactive form, only becoming activated when they reach their destination. This indeed might explain some of the observations on the alleged hormone-antihormone linkage. Certain it is that their destination is decided by some peculiar receptive capacity in the structure on which they act, catalytically or otherwise. What determines that receptive capacity we do not know as yet. But we can say that the whole process appears to be a special case of the general law that nervous stimuli, whether passing from the diencephalon to the pituitary, or down neurons to pre- and post-ganglionic endings, act through the intermediary of chemical substances locally produced. And we may find some further support for this view in the fact that, in one instance, the same substance, adrenaline, is the final product of either hormonal or nervous activity.

Historically it is interesting that in 1775 Borden wrote: "Every organ serves as a workshop for the preparation of a specific substance which enters into the blood; such substances are useful to the body, and are needed in order to maintain its integrity." Here indeed was the germ of the idea of internal secretion, which was, however, to lie dormant for more than a century. In its renaissance Victor

Horsley played an important part, though at the outset he showed a caution not always characteristic of him. It is not merely for that reason that we are here assembled to do honour to his memory. It is of the man himself of whom we are thinking— attractive, vivid, eager, enthusiastic, a very Rupert of debate, and may I say an intellectual hormone in his effect upon others. Osler tells us that in October, 1873, he listened to an introductory lecture at one of the largest of the London medical schools, the burden of which was that the art of surgery had all but reached its limits! In the falsification of that gloomy prognosis, Horsley with his pathological training, his new ideas, his fresh technique, must be allotted an honourable share. For all these reasons we honour his name and cherish his memory.

THE VALUE OF GASTROSCOPY

BY HAROLD C. EDWARDS, M.S. Lond., F.R.C.S. Eng.
SURGEON AND LECTURER IN SURGERY TO KING'S COLLEGE
HOSPITAL, LONDON

(WITH COLOURED PLATE)

THE invention in 1932 of a flexible gastroscope by Wolf and Schindler marked a new era in gastroscopy. The instrument is such an enormous improvement upon anything which had been produced previously that it has entirely replaced the older instruments, which were chiefly of the Sussmann type and semi-rigid (Fig. 1.) and has converted a somewhat dangerous and uncertain operation into one which can be performed with no risk and little discomfort. The instrument differs from its predecessors in that the part which enters the stomach is made of rubber and is thus truly flexible, and may be bent in any direction. The degree of flexibility is not much less than that of an ordinary stomach-tube, while its diameter is approximately the same. A clear vision can be obtained with the flexible part curved on the rigid part, which carries the eye-piece, to an angle not exceeding 60 degrees.

Before any method of investigation can claim a place in clinical medicine it must be shown that its value to the patient is worth any risk or discomfort entailed in its performance. It would thus be unwise to regard the recent display of enthusiasm for gastroscopy in European clinics as a correct index of its clinical value. Anyone who has examined the flexible gastroscope cannot fail to be impressed with its wonderful ingenuity, and the possibility will arise in his mind that enthusiasm begotten of the

instrument itself has unwittingly been translated into magnification of the results obtained with it, in order that its use may be justified. In other words, is it gastroscopy or is it the gastroscope which appeals? I have tried not to allow myself to be thus influenced in this attempt to assess the value of the modern gastroscope to clinical medicine.

My interest in the Wolf-Schindler gastroscope was first aroused by an editorial appearing in *THE LANCET* in 1933.¹ Soon afterwards I visited Dr. Norbert Henning's clinic in Leipzig, and later that of Prof. François Moutier in Paris, and I am greatly indebted to both these gentlemen for the generous way in which they instructed me. Immediately on my return from Henning's clinic I began to practise gastroscopy at King's College Hospital.

The Examination

Gastroscopy is done after the routine radiological investigation, so that obvious contra-indications to

it, such as oesophageal stenosis and aortic aneurysm, are avoided. There is no risk whatever if ordinary care is exercised. The examination is carried out under local

FIG. 1.—The Sussmann gastroscope (kindly lent by Mr. Arthur Edmunds) and below the latest pattern Wolf-Schindler flexible gastroscope. The Sussmann instrument is all metal, but the distal half of the Wolf-Schindler instrument is made of rubber.

anaesthesia (2 per cent. Dessicaine), after a preliminary injection of morphia and atropine, with the patient lying on his left side on a special table. As the flexible part of the instrument is no larger in diameter than an ordinary stomach-tube its passage is not a matter of great difficulty, and neither does it cause any great distress to the patient. In both respects there is, naturally, considerable variation in different individuals, and both diminish as the experience of the operator increases. So far there has been no failure to pass the gastroscope.

¹ The Flexible Gastroscope, *THE LANCET*, 1933, ii., 813.

After the instrument has passed through the cardia the rest of the introduction is made under vision, the stomach being moderately distended with air from a bellows attached to a special arm near the eye-piece of the gastroscope. The patient is conscious of a dull pain if the instrument presses at all upon the greater curvature, and this may give rise to considerable distress in the nervous subject. It is, however, not always necessary to bring the gastroscope into contact with the greater curvature; in the event of its necessity it may be done so gently that the discomfort is slight and transient.

Distension of the stomach with air does not cause much distress provided it be of moderate degree and the air be not forced in too quickly. The chief distress to the patient in this connexion is inability to express his apologies to the operator should he involuntarily belch up some of the air while the examination is in progress! The day after examina-

confidence declare what area of the stomach he has in the field of the gastroscope at any given time. He must learn to distinguish the greater from the lesser curvature by the character of the mucous membrane alone, and by the same token to distinguish the anterior from the posterior wall. The stomach as viewed through the gastroscope differs vastly from all conceptions of it derived from previous anatomical, physiological, and radiological studies. Its normal gastroscopic appearance and motility can be learned only by actual practice upon the living subject; for experience upon the cadaver or upon the phantom stomach—however ingeniously the latter be constructed—is entirely without value.

The area which may be inspected in the average case is shown diagrammatically in Fig. II. The fundus of the stomach—that is, the part under the diaphragm situated at a higher level than the cardia—cannot be seen. In most of the cases this applies also to the greater curvature aspect of the antrum. The pylorus itself is visible in rather more than half the cases—excluding those in which there is midgastric stenosis. The ability to see it depends largely upon the angle which the antrum makes with the body of the stomach. Frequently the pylorus may be clearly seen when relaxed, but as it contracts it disappears out of the field behind the greater curvature wall of the antrum, or vice versa.

The view obtained of the stomach wall is not distorted and is perfectly clear—as clear every bit as that to be obtained of the bladder at cystoscopy under ideal conditions. In the normal stomach the mucous membrane is of an orange colour and thus differs from the white appearance of the normal mucosa in the bladder and rectum. At first sight, indeed, the normal stomach appears to be inflamed because of this. The very powerful illumination given by the gastroscope causes very complex light effects, the light being reflected brilliantly from the moist surface of the stomach so that that part of the field which faces the light may appear to be of a dazzling pink-white, whereas the periphery is of a darker orange. The complexity of the effects produced is due to the presence of the numerous folds. This lighting effect, however, in no way interferes with the identification of pathological changes once the operator has got used to it.

LANDMARKS

The two chief landmarks are, I think, the antrum above (the patient lying on his left side) and what is described by French authors as the "lac muqueux" below. This collection of mucus gathers at the most dependent part of the stomach, which in the lateral position is at the splenic aspect of the greater curvature; it is seen as a brilliantly white area. The antrum in front, though it can always be recognised provided there is no mid-gastric stenosis, varies considerably in appearance (Fig. III. on Plate). On occasion it is merely a narrowing of the stomach whose folds may not completely surround the stomach, but form only two-thirds or even a half of a circle. In this condition the wall of the antrum is relaxed. When a peristaltic wave comes down the stomach, however, the antral wall becomes more clearly defined and on occasion it may contract in a sphincteric manner so that the antral chamber is momentarily shut off from the body of the stomach. At first the gastroscopist may think that he is looking at the pylorus, so complete is this sphincteric action.

The lesser curve can readily be distinguished from the rest of the stomach because it contains few or no rugæ, but shows a glistening smooth surface to

FIG. II.—Diagram to show the area of stomach which may be inspected by means of the flexible gastroscope. The fundus (A) cannot be seen. The greater curvature aspect of the antrum is usually obscured by the pillar of the antrum (B and D). The pylorus (B and D) may be seen in the majority of cases. At C is a lake of mucus, which obscures the mucosa in this area.

tion the patient complains of a little soreness of the throat, but has no other discomfort.

Though as yet I lack the opinion of a patient who has experienced both, it is my impression that the discomfort of gastroscopy is no greater than that of cystoscopy. A further comparison of the two is, however, unfavourable to gastroscopy. In the first place the duration of the examination in gastroscopy should not exceed 5-6 minutes, so that the examiner has less time at his disposal. Secondly, the stomach does not lend itself as readily as the bladder to visual inspection, and difficulties of orientation are far greater. The stomach cannot be uniformly distended, nor can an even pressure be maintained in it. It moves continuously during the examination. This movement is partly due to the excursion of the diaphragm, the stomach moving as a whole, and partly to peristalsis. The latter is the more disturbing to the gastroscopist. As a result of peristalsis the shape of the stomach is continually changing, and consequently some of the landmarks which the gastroscopist uses as a guide to orientation change their relation one to another from one moment to the next. It is thus a matter of great difficulty to get to "know one's way round" the stomach, and although, as on the cystoscope, there is a small knob on the eye-piece which indicates the direction in which the objective lens is pointing, considerable experience is required before the operator can with

the observer. On the anterior and posterior walls the rugæ are numerous and well defined. They form a very complex pattern, but their chief direction is parallel with that of the long axis of the stomach.

As has been stated, the pylorus can be seen in the majority of the cases, but it may be necessary to wait for a considerable time for it to come into the visual field (Figs. III. and VII. on Plate). Normally, it is obscured by the upper and anterior part of the antral fold and it is not until a wave of peristalsis comes down the stomach that it swings into view. The mode of its contraction may be clearly observed in some cases where it is in the visual field all the time. When relaxed it shows as a wide opening with a slightly crenated margin. Through it the mucous membrane of the duodenum can be seen, but this is not sufficiently illuminated for one to observe detail. Its contraction occurs rapidly and the greyish-coloured opening disappears as the walls of the pylorus come together. When closed the pylorus is seen as a dimple from which radiate a number of fine lines. As the pylorus closes a little of the duodenal mucous membrane is forced through into the stomach and with this a spurt of bile comes through from the duodenum. Should there be any doubt in the mind of any that duodenal regurgitation is a normal feature of the pyloric action, inspection of the behaviour of a pylorus in the normal stomach would convince him that it is a very real thing. Throughout the whole examination, as has been said, the stomach is in constant movement, partly from external forces and partly because of peristalsis.

Appearances in Disease

Thus the gastroscope, whose introduction into the stomach is not attended by any great degree of discomfort, enables a direct inspection of the greater part of the mucous lining of the stomach. What helpful data may the gastroscope therefore add to those derived from clinical, radiological, and chemical investigations in cases of gastric disorder? The answer to this question is best considered under separate headings.

GASTRIC ULCER

An ulcer of the lesser curve can always be seen unless it is of small size and lying between two folds of the stomach. The first time an active ulcer is seen a very striking impression is made upon the investigator. It looks what it really is—a great angry sore. Its edges are swollen with œdema and intensely red, and its base is covered with a light yellowish or grey slough. The œdema at the margin of the ulcer produces an edge which is raised into the stomach and thus the ulcer is crateriform (Fig. IV. on Plate). If observed in section it would be thus:

As a result of the œdema the thickness of the stomach wall at the margin of the ulcer is considerably greater than the normal. In an inactive type of ulcer, or rather during the stage of quiescence of symptoms, this œdematous appearance is lost and the ulcer in consequence appears to be a great deal shallower, although the degree of actual penetration of the stomach wall is probably the same in both (Fig V. on Plate). This confirms what I believe Barclay² was one of the first to point out—viz., that the very deep crater shown in a radiogram of an active ulcer is not due to penetration of the coats of the stomach so much as to the wall of œdema built up at the ulcer edge, causing this to project into the stomach; and that the rapid disappearance, or rather diminu-

tion of the size of the ulcer crater, which follows on treatment, is due not to the healing of the ulcer but to the resolution of the œdema. In less active types the base is greyish and inert looking, and the rugæ are drawn together towards the ulcer so that the latter bears the same relation to them as does the axle of a wheel to the spokes. It is not too much to say that one gets an entirely new conception of a gastric ulcer when it is shown up thus in its true colours, and one can far more readily appreciate the suffering which it is capable of causing. Moreover, through the gastroscope one may be able to witness the upsetting effect of the presence of an active ulcer upon the normal movements of the stomach.

Of what practical value is this ability to see gastric ulcers? In what way, if any, does the gastroscope help the clinician? The patient is being submitted to a degree of discomfort by gastroscopy. To what extent may he benefit? Is his gain worth the price he is paying for it? These are the questions which demand an answer before gastroscopy can be accepted as a routine measure in the investigation of gastric ulcer cases.

First, *diagnosis*. Is the gastroscope of value? The answer to this, I think, is yes, but only in cases of doubt. The vast majority of gastric ulcers may be demonstrated radiologically, and with little or no discomfort to the patient. In every clinic, however, there are a certain number of cases in which the clinical history strongly suggests the presence of a gastric ulcer, but in which radiography shows no more than persistent irregularity of the lesser curvature or sometimes of the greater curvature. In such cases gastroscopy is of immense value. The gastroscopist is able to concentrate his attention entirely upon the area of the stomach under suspicion and can readily determine whether or not an ulcer is present. Gastroscopy here is every bit as reliable a diagnostic measure as exploratory laparotomy—and how frequently has this been done in the past with inconclusive results—and, it is needless to add, immeasurably safer and less disturbing. Already in my experience a small ulcer on the anterior wall of the antrum near the lesser curve has been demonstrated by the gastroscope in a case in which X rays showed only persistent spasm of the greater curvature opposite to this situation (Case 1).

A further use of the gastroscope lies in *differential diagnosis*. A large ulcer crater is demonstrated radiologically—is it malignant? The good view yielded by gastroscopy may, as will be discussed later, enable this question to be answered with certainty.

Thus for diagnosis. How far may *treatment* be affected? It is not practicable to use the gastroscope as a direct means of treatment, such as making an application of drugs to the ulcer. It is thus of no value in this connexion. But its use here lies in checking the results of medical treatment, in which we have so far had no absolute criterion of complete cure. The disappearance of symptoms, and of occult blood from the stools, and even of the ulcer crater as shown radiologically, are not entirely reliable guides. By gastroscopy a much greater degree of certainty is achieved. Already in two cases in which the criteria given above were present, a small ulcer crater could still be demonstrated by gastroscopy. Such knowledge well repays the patient for the discomfort of the examination, for it either may bring about the termination of the weary process of dieting or prevent it being stopped prematurely. Thus may gastroscopy be claimed of value in relation to

² Barclay, A. E.: THE LANCET, 1929, II., 1213.

gastric ulcer: (a) in cases of doubtful diagnosis; (b) in differential diagnosis; or (c) as a criterion of medical cure.

NEW GROWTH

Most cases of carcinoma of the stomach do not find their way to the surgeon until a stage has been reached when the diagnosis is made only too readily by clinical examination and easily confirmed by X rays. There are cases, however, in which doubt exists as to whether the symptoms are due to a peptic ulcer or to a growth, or whether a peptic ulcer is becoming malignant—the clinical and radiological evidence being equivocal. Here the gastro-scope offers the most adequate means of coming to a decision. The degree of infiltration; the presence of secondary nodules, the friability of the edge, and the readiness to bleed, are all signs of malignancy which the gastro-scope is capable of revealing. In fact one has the enormous advantage of direct inspection. Just imagine how hampered we should be, say, in making a differential diagnosis of an ulcer of the tongue had we to rely on the history and a radiogram showing the extent and shape of the ulcer cavity! How many errors we should make, and yet how simple a matter it is as a rule to diagnose with certainty a malignant ulcer of the tongue just by looking at it. By gastroscopy we are offered the inestimable advantage of being able to look directly at the ulcer. Herein lies one of its greatest values—in this differential diagnosis between a peptic ulcer and early carcinoma. I do not claim that in every case a differentiation is possible—is it so in carcinoma of the tongue by inspection? But I do plead that it adds enormously to the present routine methods of diagnosis.

In three cases (Nos. 2, 3, and 4) in my series, in which the clinical and radiological diagnosis was ? carcinoma of the pylorus, the gastro-scope showed a normal stomach, with the motor function of the pylorus unimpaired. All three were operated upon. In one there was a narrowing of the pylorus with no sign of growth or ulcer (Case 3). In a second there was some thickening along the greater curvature, starting at the pylorus (Case 2). A gastro-enterostomy was performed, and seven months later the patient reported well, having put on weight. In the third (Case 4) the stomach was normal, and the cause of the symptoms was found to be a carcinoma of the head of the pancreas.

The radiologist has made possible of recent years the diagnosis of simple tumours of the stomach, as also that borderline condition of polyposis ventriculi. Here the gastro-scope will confirm with absolute certainty such diagnoses.

CHRONIC GASTRITIS

Previous to my experience of gastroscopy, largely perhaps as a result of surgical bias, I had regarded a diagnosis of chronic gastritis with suspicion. I had the feeling, no doubt shared by many, that such a diagnosis was in reality a cloak for ignorance. But I now recognise the condition as a very definite clinical entity, and one which is not so very rare.

Changes in the mucosa consistent with such a diagnosis are, in fact, seen through the gastro-scope fairly often. These changes exist in a confusing variety of forms. Basing them on gastroscopic observation, Moutier describes four main varieties of chronic gastritis, with no less than fourteen sub-groups. My own observations have so far enabled me to distinguish only three distinct types: (1) superficial or catarrhal, (2) hypertrophic, (3) atrophic.

Superficial or catarrhal.—In this condition the pathological changes appear to be limited to the surface layers of the mucous membrane, and little change is to be observed in the rugæ. The most characteristic feature is an alteration in colour from the normal orange to a dull red, and a loss of that lustre which, in the normal, reflects the gastro-scope light very brilliantly. The mucosa appears to be thickened, and there is an excess of mucus, which collects between the folds. There may be small superficial erosions, from which a little blood may ooze.

This form of gastritis is most frequently seen in association with a gastric ulcer or carcinoma, and is localised to the area of stomach wall in the immediate vicinity. It may also be seen in very characteristic form surrounding the stoma of a gastrojejunostomy (Fig. X. on Plate).

Hypertrophic.—This condition is characterised by thickening of the rugæ, with deepening of the intervening furrows in consequence. In extreme examples, according to Moutier and other observers, the stomach may develop a mamillated appearance, or fringes of thickened mucosa project into the stomach like polypi. Erosions are seldom seen, there appears to be little tendency to bleeding, and there is no excess of mucus. The condition most commonly exists independently of ulceration or growth (Fig. VIII. on Plate).

Atrophic.—This condition may be readily recognised by the thinness and paucity of rugæ. The mucosa is of a paler hue than normal, and it may be possible to see the larger blood-vessels, which are normally invisible, as they traverse the submucosa. Atrophic gastritis is a rare form of the disease; it is usually associated with one of the anæmias, and is probably not primarily a lesion of the stomach (Fig. IX. on Plate).

It is well known that the diagnosis of chronic gastritis, more particularly of the hypertrophic type, may be made radiologically; without in the least disparaging the use of X rays in this connexion, I have no hesitation in declaring that gastroscopy offers a surer means of diagnosis, especially in the earlier stages of the disease.

POST-OPERATIVE LESIONS—GASTROJEJUNAL ULCER

The mass of literature which has grown up in recent years relating to the diagnosis of gastrojejunal ulcer is eloquent of the uncertainty which at present attends it. I hesitate to make any statement about the incidence of gastrojejunal ulcer for fear of reawakening the now latent enthusiasm of those who wrote so extensively on the subject a few months ago. Nevertheless, it should be made clear that most published statistics of the incidence of anastomotic ulcers include a large number of cases diagnosed by symptoms alone.

The mere appearance of symptoms suggestive of ulcer after a gastro-enterostomy has been performed is no certain criterion of the presence of an actual ulcer at the anastomosis; and X rays, though of immense value on occasion, cannot reveal ulcers here with anything like the precision they reveal ulcers of the lesser curve of the stomach. Symptoms identical with those of a chronic gastrojejunal ulcer may arise from a chronic non-ulcerative inflammation surrounding the stoma. I cannot do better than quote the view expressed by Dr. Hurst in this connexion:³

"A good deal of disagreement about the incidence of the complications of gastrojejunostomy arises from the fact that many surgeons are unaware that a severe gastrojejunitis on both sides of the anastomotic line, with or without superficial erosions, is as common a cause of serious symptoms as a chronic ulcer, and is generally responsible for recurrent hæmorrhage in the absence of pain. This condition cannot be recognised with the X rays nor by inspection of the anastomosis in the course of an operation, with the result that the abdomen is often

³ Hurst, A. F.: Brit. Med. Jour., 1931, 1, 897.

closed after dividing adhesions or some other equally futile procedure. If partial gastrectomy is performed the true nature of the condition is discovered and the patient cured."

My experience thus far has been limited to the examination of three cases in which on clinical grounds there were the strongest reasons for suspecting the presence of a gastrojejunal ulcer following gastro-enterostomy; the radiograms were inconclusive. The intervals following operation were 7, 5½, and 2½ years, and, as far as could be ascertained from the history, the gastro-enterostomy had in each case been performed for the cure of duodenal ulcer (Cases 5, 6, and 7). In all three I was able to make a close inspection of the stoma. I do not know whether I was unusually lucky in bringing all three stomata into the field, although theoretically it should always be possible to see the opening when situated on the body of the stomach, whether anterior or, as of course is more usual, posterior. The view is limited to the gastric aspect, needless to say. A portion of the jejunal mucous membrane may, however, be seen if conditions are favourable.

In no case was a gastrojejunal ulcer present. In all, however, the area of stomach surrounding the anastomosis had the characteristic appearances (already described) of chronic superficial or catarrhal gastritis, two of them with small erosions. In one case the persistence and severity of the symptoms led to operation, and the gastroscopic findings were confirmed (Case 5).

In the light of this experience it is clear that the gastroscope is a very valuable help in the elucidation of suspected trouble in the neighbourhood of a gastro-jejunal stoma. I would even go further and say that the gastroscope is the only sure means of diagnosis.

RARE CONDITIONS

In tuberculous disease or syphilis of the stomach or in conditions such as chronic intussusception through a gastro-enterostomy stoma, it seems probable that gastroscopy would be a very useful adjunct to radiological diagnosis, although as yet none of these rare conditions has come under my observation.

Case Records

The following cases illustrate the value of the method.

CASE 1.—Man aged 39. Complained of pain in the stomach 1½–2 hours after meals, and relieved by sickness. Symptoms began about six years ago, but there had been long periods of remission. In 1930 was radiographed at another hospital and a gastric ulcer reported (? position). Had been treated medically for the past two years. Radiography showed persistent spasm of the greater curvature of the antrum, but no ulcer. Gastric residuum showed hyperacidity.

Gastroscopy (Feb. 2nd, 1935).—Oval shallow ulcer on lesser curvature of antrum. Nil else abnormal. Operation advised, but refused.

CASE 2.—Man aged 65. For 12 months had complained of pain in the epigastrium with some loss of weight. The pain had no relation to meals and was practically constant. He vomited on one occasion and the appetite was poor. Radiography showed a filling defect at the pylorus, and the report queried the possibility of carcinoma of the pylorus. Gastric residuum showed low total acid and no free acid.

Gastroscopy (Feb. 19th, 1935).—Very easy examination and a good view of the distal two-thirds of the stomach obtained, though residue prevented inspection of the proximal end of the posterior wall. Both the pylorus and the antrum were clearly seen. Peristalsis was active and there was no sign of growth. The mucous membrane was healthy.

Operation (Feb. 22nd).—There was some thickening extending from the pylorus for a little distance along the greater curvature, but no actual growth was evident. The stomach was opened and the antrum and pylorus were explored with a finger. No sign of ulceration was present. In view of the thickening at the pylorus gastro-enterostomy was performed. When seen on Sept. 12th he was feeling very well and had put on weight.

CASE 3.—Man aged 54. Vague history of indigestion for many years. During the past three weeks had complained of pain in the epigastrium and sickness. Appetite poor. ? Loss of weight. Examination of the abdomen revealed a rounded immovable mass to the right of the umbilicus, corresponding with the position of the pylorus as shown in the radiogram. X rays showed a five-hour residue in the stomach with a fixed deformity at the pylorus. ? ulcer ? new growth. Gastric residuum showed a high normal acidity. The association of a mass with deformity at the pylorus, together with the history, seemed to make a diagnosis of carcinoma of the pylorus, despite the gastric acidity, a reasonable certainty.

Gastroscopy (Sept. 4th, 1935).—Complete and easy examination. Pylorus normal.

Exploration (Sept. 9th).—Despite the negative gastroscopic finding, the clinical and radiological findings appeared to make operation imperative. The fixed mass proved to be an ectopic kidney of normal size and shape. The pylorus appeared to be normal to inspection and palpation. A small incision was made in the stomach and the pylorus explored with the finger. Apart from the fact that the pyloric ring appeared to be narrower than is usual, no abnormality was found, and the findings at gastroscopy were thus confirmed.

CASE 4.—Man aged 66. Three months' history of pain in the epigastrium. Practically constant and no relation to food. Occasional vomiting with poor appetite and some loss of weight. A history of coffee ground in the vomit on one occasion. X rays showed a deformity at the pylorus which suggested an ulcer in this situation although no crater was to be seen. Gastric residuum showed acid content to be within normal limits.

Gastroscopy (May 3rd, 1935).—Examination was not satisfactory as there was too much residue in the stomach. The patient then spent some time in the hands of the dentist and on May 22nd a second gastroscopy was done. Complete examination was possible and the pylorus was seen to be quite normal. Neither growth nor ulcer was present. The mucous membrane was pale and atrophic.

Operation (May 24th).—Carcinoma of the head of the pancreas was found growing upwards towards the first part of the duodenum. The stomach was normal.

CASE 5.—Man aged 39. Long-standing history suggesting a chronic duodenal ulcer. Two and a half years ago appendicectomy was performed and two years ago a gastro-enterostomy, both at another hospital. One year ago he had been under observation for a return of pain, also at another hospital. He complained of pain similar to his old trouble in incidence but situated to the left of the midline, and there was some tenderness on abdominal examination above the umbilicus. Radiography showed a gastro-enterostomy stoma which appeared to be working satisfactorily. The gastric residuum showed achlorhydria with only a mild response to histamine.

Gastroscopy (May 3rd, 1935).—Complete examination possible. Pylorus normal. The stoma was seen and appeared to be of adequate size, but the mucous membrane of the stomach surrounding it was reddened and swollen from oedema (Fig. X. on Plate). Two small erosions were present.

Operation (May 17th).—There was no naked-eye evidence of a duodenal ulcer and the pylorus was patent. The gastro-enterostomy stoma was examined and no ulcer found, although there was considerable redness of the peritoneum in the neighbourhood. The stoma was excised and the parts restored to their normal relations. Pathological report on a section of the stoma showed inflammatory infiltration of submucosa consisting of polymorphonuclears, eosinophils, and plasma cells.

CASE 6.—Man aged 59. Gastro-enterostomy had been performed for duodenal ulcer five and a half years ago.

After a period of relief of some months only, he began to experience abdominal pain again. This resembled in character the pain before operation, but relation to food was less defined and it varied in intensity from day to day, though there were no periods of complete remission. Latterly it had become more constant. X rays showed a gastro-enterostomy stoma apparently functioning satisfactorily. Gastric residuum showed a low normal acidity.

Gastroscopy (April 4th, 1935).—The pylorus was not seen. The mucous membrane of the distal half of the stomach appeared to be normal. The gastro-enterostomy opening was seen on the posterior wall, near to the greater curvature. The surrounding area was scarred, and the gastric mucous membrane at the margin of the stoma was pale and cedematous. There was no ulcer.

CASE 7.—Man aged 33. Previous history suggesting duodenal ulcer, for which a gastro-enterostomy had been done seven years ago. This was followed by complete relief from symptoms until six months ago, when epigastric pain returned, accompanied by occasional sickness. On two occasions there had been blood in the vomit. X rays showed the gastro-enterostomy stoma to be working, apparently satisfactorily. Gastric residuum showed a low normal acidity.

Gastroscopy (March 3rd, 1935).—Pylorus seen and working normally. Distal two-thirds of stomach normal. The edges of the gastro-enterostomy stoma were well defined, and there was no contraction. The rugæ in the neighbourhood were much hypertrophied, and the mucous membrane reddened. At one point there was an erosion.

Summary

The examination of gastroscopy, carried out with the new Wolf-Schindler flexible gastroscope, is entirely without risk, and its performance does not cause much discomfort to the patient.

The gastroscope permits of direct inspection of the greater portion of the lining of the stomach, but experience is necessary in order to interpret the findings, and particularly to master the technique of orientation. Gastroscopy does not in any way replace or rival X ray examination, which should always be performed before gastroscopy is contemplated.

Gastroscopy may be a useful adjunct to radiological examination in the diagnosis of gastric ulcer, especially in obscure cases, and may be of value to the clinician in checking the results of medical treatment.

It is of the greatest assistance in cases of suspected

carcinoma when the clinical and radiological findings are equivocal. It is the best means at our disposal of making a diagnosis of chronic gastritis, and also of the nature of morbid conditions affecting the stoma in gastrojejunostomy. Finally, gastroscopy may be the means of saving the patient an operation.

The gastroscope has therefore a definite field of usefulness in the management of cases of gastric disorder, and with increasing experience of the operator, and perhaps when still further improvements are made in this most ingenious instrument, this field of usefulness will be more widely extended.

CYSTS OF THE SEMILUNAR CARTILAGE OF THE KNEE

By JOHN P. HOSFORD, M.S. Lond., F.R.C.S. Eng.
TEMPORARY ASSISTANT DIRECTOR, SURGICAL PROFESSORIAL UNIT,
ST. BARTHOLOMEW'S HOSPITAL

(WITH ILLUSTRATIONS ON PLATE)

In 1904 Ebner reported the first case to be recognised of a cyst of the external semilunar cartilage of the knee. Since then cysts of the semilunar cartilages have been reported in gradually increasing numbers; the condition is not uncommon and most orthopaedic surgeons probably meet several cases a year. In all the six cases seen at St. Bartholomew's Hospital in 1934, recorded below, histological sections of the cysts and adjoining cartilage were made and it is thus possible to discuss their pathology and origin as well as their clinical manifestations.

This peculiar cystic change in the semilunar cartilage is found about five times as frequently in the external cartilage as in the internal, and males are affected more commonly than females. It usually occurs between the ages of 20 and 30, although it has been recorded in patients over 50 (Ollerenshaw). There is often a history of trauma though this is not in any way as characteristic or constant as in cases of injury to the cartilage. It is difficult to appreciate the exact relationship between trauma and the origin of these cysts, because an injury to

FIG. III.—A view of the antrum partly contracted. The pylorus is almost fully contracted.

FIG. IV.—An active ulcer of the stomach situated on the lesser curvature aspect of the antrum. Much "catarrhal" gastritis coexists. The mucosa is intensely reddened and swollen so that the rugæ are almost obliterated and there are a few small erosions, one of which is to be seen in the left pillar of the antrum. The patient was a man of 53, who had had symptoms of epigastric pain of 14 days' duration. There had been no previous gastric history.

FIG. V.—A callous ulcer situated on the posterior wall of the stomach near the greater curvature. The rugæ in the neighbourhood are considerably thickened but there is little or no œdema at the edge of the ulcer.

FIG. VI.—Carcinoma of the stomach. A large growth with necrotic surface growing from the posterior wall

and encroaching upon the lesser curvature near to and obscuring the pylorus. X rays showed a 7-hour delay of barium in the stomach.

FIG. VII.—The pylorus semi-relaxed. The stomach in this case was atonic and little peristalsis was observed.

FIG. VIII.—Chronic hypertrophic gastritis. Hypertrophy of the rugæ with increased vascularity of the mucous membrane.

FIG. IX.—Chronic atrophic gastritis from a case of pernicious anaemia. The mucous membrane of the stomach is pale and the rugæ are small and poorly defined. Owing to atrophy of the mucosa the blood-vessels of the lesser curvature can be clearly seen.

FIG. X.—Gastro-enterostomystoma. (Case 5.) The gastric mucosa is swollen and cedematous. There is excess of mucus and there are two small erosions near the orifice.

FIG. IX.

the knee of one sort or another is so common. The associated history, however, occurs so often that it cannot be neglected.

Usually the patient seeks advice because of a continuous discomfort in the whole knee, aggravated by exercise, and unless the possible presence of a cyst is remembered the surgeon as well as the patient may overlook it. Sometimes he helps in diagnosis by complaining of a swelling on the outer side of the knee, slightly tender, and becoming more painful after exercise. Occasionally the history is that the knee "lets the patient down"; but never that the knee-joint locks. Not uncommonly the knee swells after vigorous exercise.

On examination, when the cyst is of the external semilunar cartilage, a swelling is found on the joint line above and a little anterior to the head of the fibula and to the external lateral ligament. The swelling may be so small as to be hardly perceptible or as large as a walnut. Fluctuation may or may not be obtainable depending on the size and tenseness of the cyst. The range of movements of the joint are in most cases full and painless and neither clicking nor grating are felt. Springing of the external lateral ligament causes no pain; on the other hand, when the tibia is abducted on the femur pain is sometimes felt on the outer side of the joint, presumably produced by compression of the enlarged external cartilage. So far as is known these cysts do not tend to disappear spontaneously although a number of patients say they get smaller and the pain gets less when the knee is rested, only to return when activity is resumed. A skiagram of the joint does not usually show anything abnormal, although occasionally there may be considerable erosion of the tibia, as in the cases reported by Fairbank and Lloyd.

CASE 1.—A. B., male aged 33, a clerk. 1929. Following a "twist of the knee" at football, there was an effusion into the right knee, which gradually subsided. On patient recommencing football three months later a swelling appeared at the outer side of the knee. It got larger and more painful whenever he played games, and improved when he rested. When he kept the leg still in one position for any length of time the knee ached; this had recently interfered with sleep.

February, 1934: The cyst was removed together with the external semilunar cartilage.

CASE 2.—C. D., male aged 24, an accountant. December, 1933. There was no history of injury but patient noticed pain in his left knee while playing football. Even after rest for a month he was unable to continue playing for more than ten minutes, since the whole knee became painful. The pain was always felt throughout the joint, and was not confined to one spot.

April, 1934: The cyst was removed with the external semilunar cartilage.

CASE 3.—E. F., female aged 23. October, 1933. While going downstairs her right knee "gave way" but

did not lock. This recurred on four occasions. February, 1934, patient noticed a swelling on the outer side of the knee; it gradually increased in size. There was no history of injury.

April, 1934: The cyst was removed with the anterior three-quarters of the semilunar cartilage.

CASE 4.—G. H., male aged 26, a clerk. In 1932 the right knee swelled up following football; this recurred on several occasions and caused pain. It always recovered with rest, but never locked. A history of a number of blows on both knees was obtained.

August, 1934: Mr. S. L. Higgs removed the cyst together with the external semilunar cartilage to which it was attached.

CASE 5.—I. J., male aged 26. March, 1933. While patient was playing football the right knee became painful on the outer side. The pain recurred a number of times so that he had to give up playing. Apart from vigorous exercise it was not painful.

September, 1934: The cyst and cartilage were removed by Mr. C. N. Morgan.

CASE 6.—K. L., male aged 24, a gas worker. May, 1934. Aching in the left knee and pain on bending were first noticed when walking. Patient was treated elsewhere for synovitis with rest for six weeks. There was little improvement and the knee remained painful, especially when resting. September, 1934, he noticed a swelling on the outer side of the joint. The knee never locked but it felt unsafe when at work on a ladder. There was no history of definite injury.

October, 1934: The cyst and most of the external cartilage were removed. Within a month the man was able to run upstairs and walk six miles, the pain having completely disappeared.

These cases have been followed up in September, 1935. All are completely free from symptoms, have full use of the knee, and no return of the swelling.

MORBID ANATOMY

Macroscopically, after removal at operation, these cysts are almost always seen to be multiple. They are small in size, varying from that of a pin's head to that of a pea. They are deep to the capsule of the joint and involve and are attached to—in fact are part of—the semilunar cartilage. They are situated on the outer convex border of the cartilage, usually about half-way along its antero-posterior length. When a cross-section of this part of the cartilage is examined the internal sharp concave border is seen to be normal and unaffected. As the section is followed outwards, the cartilage becomes a little thicker than normal, giving the appearance of being expanded with a softer central portion. In the outer part of the section a number of cysts are seen, bulging into the surrounding tissues, as well as involving the cartilage. Some of the cysts are separated from one another by a definite thickness of cartilage, while others are so close together, being separated only by the thinnest membrane, that they might be called multilocular. The cysts contain a somewhat thick,

mucoïd, clear, colourless, or slightly brownish material. The remaining portions of the semilunar cartilage, anterior and posterior to the parts affected by cysts, appear to be normal, as do the adjacent articular surfaces of the tibia and femur.

The typical microscopical changes are as follows. Passing outwards from the normal fibrocartilage at the inner concave edge, we come to a region of scattered areas of mucoïd degeneration (Fig. I. on Plate); a little further out may be seen a number of very small spaces with well-defined edges and containing material which takes up the hæmatoxylin stain—apparently mucoïd substance. Further out are much larger but compressed spaces which are the collapsed cysts, some being as large as a pea and containing thick mucoïd fluid. In some sections the arteries at the outer edges of the cartilage appear greatly thickened, almost to the degree of an obliterative endarteritis (Fig. II.).

THEORIES OF ORIGIN

Several hypotheses of origin have been put forward. Ollerenshaw has insisted that the cysts are lined by endothelium and believes them to be developmental in origin. Goldzieher, reporting on Kleinberg's case, describes the cyst as lined by a layer of flat endothelial-like cells and probably arising from lymph vessels. Fisher believes that these cysts are ganglia which originate between the peripheral surface of the external cartilage and the synovial membrane with which it is covered at this spot. Allison and O'Connor suggest that the cysts are the end-result of a degenerative process due to interference with the blood-supply of the cartilage. King concludes by saying that the cysts are compatible with ganglia. His views will be referred to later.

In support of the first two theories, viz., those in which a developmental or a lymphatic origin are propounded, a layer of endothelial cells lining the cysts has been described. A good deal of discussion has arisen in the past as to whether endothelial cells are present or not. A difficulty always liable to arise in studying microscopically a single-layer of cells lining a cavity is that during the preparation and cutting of the section the cells may become detached and lost. However, in a number of published microphotographs and drawings of sections of cysts of the semilunar cartilages, and in sections from a recent case, a layer of lining cells at first sight resembling endothelial cells is clearly seen. This, however, is only seen in the larger cysts. In the very small cysts no endothelial lining cells can be seen, although the cysts are still filled with mucoïd material (Fig. III.). It is difficult to imagine that a layer of endothelial cells could become detached from the cyst-wall during the preparation of the section while the mucoïd content of the cysts remains in position. The same observations as regards a true lining of cells in large as compared with small cysts have been made by Bristow. If the cells lining the cysts are studied carefully it may be observed that although they form a definite continuous layer they are not typical endothelial cells, and that, moreover, they are very similar to the cells in the immediately adjacent fibrocartilage (Fig. IV.). It is difficult to believe that these lining cells are a specific endothelium or that they are anything more than compressed cells from the surrounding fibrocartilage in which the cysts are situated. If an endothelium of developmental origin were present, one would expect not only to find it well-formed in the smaller cysts, but even more noticeable there than in the larger ones, where it would be flattened out owing to stretching. King,

using several modifications of the silver impregnation method, was able to determine the actual type of cell lining the cysts because the silver methods allow differentiation between connective tissue and endothelium. King says: "The larger cysts are lined by connective tissue and not by endothelium. This is apparent not only from the morphology in hæmatoxylin and eosin sections but also from the section impregnated by silver. In these the surface material is seen in most cases to be actual fibrous tissue and the cells are embedded in the fibrous tissue stroma. A few lie on the surface but these do not constitute an endothelium."

It is difficult to believe that Fisher is right when he says that these cysts are ganglia originating between the peripheral surface of the cartilage and the synovial membrane because an examination of a complete section through a semilunar cartilage, where a cyst is present, shows changes not only in the outer edge of the cartilage but also in the deep parts and close to the inner concave margin. Microscopically some areas of degeneration can be seen surrounded by normal cartilage and separated from the periphery of the meniscus. In view, therefore, of the facts that the cysts do not possess an epithelial or endothelial lining and that degeneration is found commencing deeply in the cartilage, the pathology must be considered to be one of *primary mucoïd degeneration* of the cartilage. The cause of this degeneration is, however, not clear. Although an endarteritis is frequently seen in sections of this condition, it does not seem to account, as Allison and O'Connor suggest, for a degeneration of cartilage, a tissue which has few or no blood-vessels in it. It is not possible to blame trauma as the actual cause of this degeneration, either on clinical or pathological grounds. No similar degeneration of cartilage following trauma is seen elsewhere in the body, although it is frequently subjected to injuries, both severe and slight.

TREATMENT

Most patients come for treatment owing either to pain or disability; few come only because of the presence of a swelling. Conservative treatment gives only temporary relief from symptoms until activity is resumed. Therefore, if pain or disability is sufficient to demand treatment, removal by operation is the only satisfactory measure. The pathological change is primary in the cartilage, therefore cysts will recur if only the macroscopic cysts are removed; the semilunar cartilage itself must be taken away also. Through a curved skin incision the fascia lata near its insertion is incised and the cyst is exposed. It is dissected from the surrounding tissues, the joint opened, and the semilunar cartilage exposed; as much of the latter as possible is then removed with the cyst attached.

RESULTS

The end-results after operation, provided there are no changes in the adjacent articular cartilage or bone, are excellent. There are neither pain, weakness, nor any disability in the joint, and the patient can use his limb fully for any games.

I have to thank Mr. Higgs and Mr. Morgan for allowing me to examine the specimens removed in Cases 4 and 5. For permission to operate on the other cases my thanks are due to Prof. G. F. Gask.

THE INCIDENCE OF CONGENITAL ABNORMALITIES IN THE GENITO-URINARY TRACT AS SEEN IN 500 CONSECUTIVE INTRAVENOUS PYELOGRAPHIES

By I. B. BARCLAY, M.R.C.S. Eng., D.P.H., D.M.R.E.

RADIOLOGIST, SELLY OAK HOSPITAL, BIRMINGHAM; AND

J. B. BAIRD, M.C., M.B. Glasg., F.R.C.S. Eng.

SURGEON TO THE HOSPITAL

(WITH ILLUSTRATIONS ON PLATE)

THE literature of congenital abnormalities of the kidneys and ureters lays great emphasis on their rarity. Our experiences at Selly Oak Hospital, using the more recent methods of urological investigation, suggest that such abnormalities are commoner than has been realised. Reviewing 500 consecutive cases referred for intravenous pyelography we have found the following congenital and other abnormalities:

- (a) Unilateral fused kidney showing two normal ureteric orifices with the left ureter crossing to the right side.
- (b) Congenital absence of left kidney with complete reduplication of pelves and ureters of right kidney.
- (c) Six cases of bilateral double ureters and pelves (two with complete reduplication and four with incomplete).
- (d) Seven cases of unilateral double ureters and pelves (two with complete reduplication and five with incomplete).
- (e) A case of probable valvular ureteric obstruction.
- (f) Two cases showing unilateral true renal ptosis.

Many writers have stated that unilateral fused kidney is extremely rare. Some object to this term because the kidneys, though crossed, may be fused only by fibrous tissue and prefer the term "crossed renal dystopia." But as it is highly unlikely that the second kidney ever lay on the opposite side—which means that it never crossed the midline—this expression is even less fortunate. "Unilateral fused kidney" is at little variance with accepted embryological findings and is a sufficiently accurate clinical term.

Pierson¹ states that up to 1932 only 103 cases were recorded. Stewart and Lodge found only one example in 6500 post-mortems; Henry Morris found one in 15,908 post-mortems. Our own series of 500 consecutive cases show one well-defined example of this condition, and one other case, which at first we thought to be unilateral fused kidney, but which we now think combines the two anomalies—viz., congenital absence of one kidney, and complete reduplication of pelves and ureters of the remaining kidney. While recognising that it is not fair to compare a routine series of cases seen at autopsy with a series of cases referred because of possibly urological signs or symptoms, the occurrence of two such cases in one year at one hospital suggests that the frequency of the condition has been underestimated.

7. Kleinberg, S.: *Jour. Bone and Joint Surg.*, 1927, ix., 323.
8. Ollerenshaw, R.: *Brit. Jour. Surg.*, 1929, xvi., 555.

In order fully to appreciate the conditions we have found it is necessary to go into certain embryological and pathological considerations.

The cortex or secreting part of the kidney—i.e., the part from glomerulus to convoluted tubule—is formed from the most caudal part of the intermediate cell mass, but the "conveying" part of the kidney (the collecting tubules, the calyces, pelvis, and ureter) is an outgrowth from the lower end of the Wolffian duct. In early embryonic life these structures lie side by side low down in the pelvis. The "outgrowth" or bud develops several branches, which are enveloped by the growing cortex or metanephros. These terminal branches are the collecting tubules of the permanent kidney. At an early stage the renal pelves and ureters lie anteriorly, but as the ureter grows cranially the kidney moves with it from pelvis to abdomen and as it does so the metanephros swings laterally and the pelvis mesially. At the end of the second month rotation into the permanent relative positions of cortex and pelvis has taken place, and by the fifth month migration upwards to loin has been accomplished; thereafter the ureter lengthens by growth caudally, not by cranial migration of the kidney.

As budding ureters and metanephros lie adjacent in the pelvis, in their earliest weeks, adjacent blood-vessels supply both, and as they climb the "ladder" to the loin they acquire new vessels at each new level. When migration has ceased most of the temporary vessels disappear but others remain to supply the structures at different levels—e.g., the inferior vesical, spermatic, and renal arteries.

Such being the normal, how is one to explain the production of (1) unilateral fused kidney, (2) renal agenesis, and (3) double ureters and pelves?

UNILATERAL FUSED KIDNEY

One cannot do more than make as good a guess as possible at what happens. There are only two broad possibilities:—

- (a) The renal masses fuse before migration; "then if this fused mass remains in the pelvis we get the pelvic fused kidney. Migration may carry the fused mass to either side or to the midline, so causing either unilateral fused kidney or horse-shoe kidney. Any extreme variation of blood-supply is not surprising." (Pierson.¹)
- (b) The kidneys develop in the normal situation and are subsequently displaced by some mechanical factor. This appears very unlikely on general grounds, but in its favour is the fact that unilateral fused kidney, unlike congenital absence of one kidney, is never associated with developmental abnormalities of the gonads, adrenals, or other structures derived from the Wolffian body and genital ridge.

Unilateral fused kidney is commoner on the right side. This may be due to rotation of the embryonic mesentery (Pierson).

It is interesting to contrast with unilateral fused kidney the congenital absence of one kidney. In the latter condition either duct fails to give off any ureteric bud on that side, or the bud fails to develop and the adult ureter is represented by a mere fibrous cord. There would, therefore, be either no ureteric orifice at all on the side concerned or at most there would be an abnormally small and blind one; whereas in a unilateral fused kidney there are always two normal ureteric orifices.

The case classified in Group B seems more likely to be a case of renal agenesis on the left side and complete reduplication on the right side, rather than one of right unilateral fused kidney; for the ureteric orifices, as seen cystoscopically and as shown on

the skiagram, are within $\frac{1}{2}$ in. of each other and are both definitely on the right side of the bladder. No ureteric orifice could be found on the left side, and though there was a very good efflux from both the right ureteric orifices, no blue came from any other opening.

In cases of unilateral fused kidney neither cystoscopy nor chromocystoscopy indicates the absence of a kidney on one side, because the ureteric orifices occupy their normal positions in the bladder. It has occasionally happened indeed that the whole renal mass, only part of which has been diseased, has been removed, the operator trusting to what he considered a good blue efflux from a kidney on the other side, for the maintenance of renal function. Hence the desirability of complete urological examination, and, especially of intravenous pyelography, which should, we think—were it not for the expense—be always an initial attack on a possibly urological case.

DOUBLE PELVES AND URETERS

As regards double ureter, there are again only two possibilities: either (a) there are two separate buds—which theory alone can explain two ureters separate in their whole length—or (b) a single ureteral bud divides into two at any point between its origin and the kidney (which explains the ureter which is single near the bladder, but double higher up). Also, as the ureteric expansions are separate, so are the cortical masses that envelop them; so that if there are two ureters there are also two distinct kidneys, fused together.

Several practical points are worth noting in cases of incomplete reduplication of the ureter, arising out of the fact that a ureteric catheter passes usually into the pelvis of the upper kidney and not into the lower.

(1) Retrograde pyelography will give a small shadow, highly placed, of the pelvis. This, when compared with the large renal shadow present, should make one suspicious and indicate that an intravenous pyelogram should be done as well.

(2) If the lower pelvis is infected the catheter may obtain an uninfected urine from the upper pelvis, and unless the presence of the lower kidney is suspected the result will be very misleading. The recovery of clear urine by catheterisation when purulent urine has previously been obtained should not be regarded as a sure sign that the infection has cleared up.

DOUBLE URETERS AND PELVES

Most writers state that the ureter from the lower kidney crossed in front of that from the upper (usually

low down), and that its orifice is always above and outside that of the upper ureter. This finding has not been borne out in our series of cases. We have found by study of lateral views with an opaque bougie in each ureter that no reliance can be placed on any assumption as to their relative positions.

Fig. I., for example, shows an upper ureter which lies at first posterior to the lower one and then crosses to lie anteriorly, at the level of the upper border of the fifth lumbar vertebrae, crossing again to lie posteriorly at the upper level of the first sacral segment, and finally crossing once more at the level of the third sacral segment. Again Fig. II. shows an upper ureter lying anteriorly at its origin, but crossing the lower at the level of the first sacral segment to lie posteriorly for the remainder of its course. The importance of these anatomical findings from the surgical viewpoint is obvious.

Case Records

We can now briefly consider the cases under review.

A.—UNILATERAL FUSED KIDNEY

CASE 1.—Mrs. A., aged 34, was admitted on July 1st, 1935, complaining of three weeks' pain on micturition. It was severe and was preceded by pain in the right loin, which had been coming round to the front for two weeks. Frequency about two-hourly. Urine on admission: cloud of albumin; mass of pus cells and blood corpuscles deposited; no casts; *Bacillus coli communis* on culture.

Intravenous pyelography (Fig. III. on Plate) showed no renal outline or function on the left side; on the right

FIGS. I. and II.—Described in text.

there was a double renal pelvis with a large kidney outline, and the lower ureter crossed to left side in pelvis. Cystoscopy on July 15th, after rest and treatment, showed mild cystitis in a bladder of good capacity. The ureteric orifices were in normal positions and of normal shape. Indigo-carmin (5 c.cm.) produced a good efflux from both ureteric orifices beginning in five minutes and regularly repeated. Later opaque bougies were passed up the two ureters and an intravenous pyelogram was taken. This confirmed the anatomical diagnosis (Fig IV. on Plate).

On her discharge the patient had no symptoms and her urine was sterile.

B.—CONGENITAL ABSENCE OF LEFT KIDNEY WITH COMPLETE DUPLICATION OF PELVES AND URETERS ON RIGHT SIDE

CASE 2.—A woman aged 21, with no noteworthy previous illnesses, was admitted complaining of pain in the back and right loin of four days' duration. Temp., 99.4° F.; pulse-rate, 80; respirations, 20. She had vomited on the day before, but had no dysuria. The abdomen showed no rigidity and there was no special tenderness over the right kidney either in front or behind; very slight deep tenderness was left over the right iliac fossa. Intravenous pyelography showed no renal outline or

function on the left side in 30 minutes. On the right the renal outline was large and there were complete double pelves and ureters. Retrograde pyelograms (Fig. V. on Plate and Fig. VI.) show clearly the two opaque catheters emerging from two separate ureteric orifices and passing up to the separate renal pelves. Chromocystoscopy showed double right ureteric orifices, the inner of which was more active than the outer, though both showed good efflux; the orifices were about $\frac{1}{4}$ in. apart. There was no evidence of any left ureteric orifice. Retrograde pyelography along both ureters confirmed intravenous findings.

It should be borne in mind that the radiographic appearances do not necessarily give the degree of true fusion present in any case; there may be complete continuity of cortical tissue or merely two separate kidneys held loosely together by connective tissue. In both the above cases, however, the renal outline was seen to be continuous, and so far as can be gathered there was true renal fusion. In both these cases there was an infection of the lower pelvis but not of the upper one; this characteristic has been noted by previous writers.

C.—BILATERAL DOUBLE URETER

The six cases in this group may be tabulated as follows:—

Complete Duplication (2)

Sex and age.	Clinical findings.	Observations.
M., 16	Pyelitis right lower pelvis.	Discharged, urine sterile.
F., 23	Pyelitis left lower pelvis.	"

Incomplete Duplication (4)

M., 34	Small calculus below fusion of ureter, right side, with hydronephroses lower pelvis.	Calculus passed. Recovery.
F., 28	Nil definite found.	—
F., 42	Pyelitis lower pelvis.	Recovery. Discharged, urine sterile.
F., 21	Enlarged upper right ureter with two faceted calculi below the fusion just above right ureteric orifice. (Case 3: Figs. VII. and VIII. on Plate).	Calculi removed by vesical route. Uneventful recovery.

D.—UNILATERAL DUPLICATION OF PELVES AND URETERS

In this group there were seven cases:—

Complete Duplication (2)

Sex and age.	Side.	Clinical findings.	Observations.
F., 20	R.	Pyelitis lower pelvis.	Discharged, urine sterile.
F., 28	L.	Hydronephrosis, &c., upper pelvis with pyelitis, poor function lower pelvis (Case 4: Fig. IX. on Plate shows catheters in both ureters and Uroselectan in upper pelvis).	Discharged relieved.

Incomplete Duplication (5)

F., 10	R.	Nil definite.	—
F., 19	R.	Pyelitis right lower pelvis.	Discharged, urine sterile.
M., 26	R.	Nil definite.	—
M., 28	L.	Pyelitis both pelves, poor function.	Discharged relieved.
F., 33	R.	Pyelitis lower pelvis with some dilatation of ureter.	Discharged, urine sterile.

It will be noted that (a) out of 13 patients with double ureters, &c., 9 were female and 4 male;

FIG. VI. (Case 2).—Opaque bougies passed through the separate ureteric orifices. (Course of bougies has been made clear.)

(b) in 9 cases showing proved pyelitis, the lower pelvis was alone involved 7 times, the upper pelvis alone once; (c) in 7 cases of unilateral duplication 5 were on the right side and 2 on the left.

E.—URETERIC OBSTRUCTION—PROBABLY VALVULAR

Other congenital abnormalities of the ureter appear to be rare and therefore of some interest. We consider the following case a striking example of an uncommon type of abnormality.

CASE 5.—Female, aged 22. Frequency of micturition throughout her life. Intravenous pyelography (Fig. X. on Plate) showed on the right side well-marked enlargement of calyces and pelvis with dilatation of the ureter, increasing to the level of the upper border of the first sacral segment. At this level the ureter, about 1.5 cm. in diameter, was seen to be well filled with the dye and showed a sharp semicircular, concave border with the concavity downwards at the site of obstruction; no further delineation of the ureter below this level was discernible on the intravenous pyelographic examination. The opposite side appeared normal.

Cystoscopy showed some cystitis with normal ureteric orifices; an opaque bougie was felt to hitch approximately 2 cm. from the right ureteric orifice. After eventually passing this obstruction the bougie was passed up to the renal pelvis and simultaneously a second intravenous injection of uroselectan was given (Fig. XI. on Plate). It is interesting to note that at approximately the level of the obstruction, just above the ureteric orifice, the ureter itself is seen to be enlarged for approximately an inch. When the bougie was withdrawn very purulent urine was discharged. This urine showed a large mass of pus cells and organisms. The kidney was removed together with the ureter to the level of the upper border of the fifth lumbar vertebra. Unfortunately it was not possible to take the ureter to the level of the obstruction as seen in the intravenous pyelogram. When examined

later the ureter was seen to be much hypertrophied with the wall increasing in thickness from the pelvi-ureteral junction downwards. There was no obvious evidence of valves in the specimen under observation, though it is difficult to explain the appearances found upon any other suggestion. There was no question of calculus being present either during the time the patient was under observation or (so far as we can ascertain) at any time previously.

Valves in the ureter are well known at the junction of the pelvis of the kidney with the ureter, and also at the entrance of the ureter into the bladder. We have been unable to find any definite references to the presence of valves in other parts of the ureter giving rise to obstruction.

In view of—

- (1) The definite obstruction demonstrated by intravenous pyelography;
- (2) The difficulty encountered in passing an opaque bougie along the initial 2 cm. of the ureter above the ureteric orifice;
- (3) The dilatation of the ureter just above the orifice as depicted in the intravenous pyelogram combined with the opaque bougie (Fig. XI.);
- (4) The passage of the purulent urine upon withdrawal of the bougie (i.e., through the upper obstruction);
- (5) The fact that all the disease discovered appeared above the level of the first obstruction;
- (6) Her lifelong history of frequency of micturition;
- (7) And the well-marked hypertrophy of the ureter, with no present or obvious evidence of any calculus being present,

we suggest that our findings are those of partial obstruction arising out of the presence from birth of abnormal valves in two locations: (a) just above the ureteric orifice; (b) in the ureter at the level of the first sacral segment.

F.—RENAL PTOSIS

Throughout our series only two cases have shown definite evidence of ptosis of one kidney. Slight differences of level in the upper or lower poles during inspiration and expiration have been noted, but in these two cases only has there been any anatomical state of true ptosis. The patients were both women and both had well-marked pyelitis; in one of them, aged 51, there was also definite hydronephrosis (Fig. XII. on Plate).

We feel that a series of 500 cases showing such abnormalities as have been described would have demonstrated a large number of "dropped" or "floating" kidneys if such a condition was fairly common, especially as most of our cases are drawn from the poorest inhabitants of Birmingham, some of whom have been unemployed and have probably found it extremely difficult to obtain sufficient food. We therefore suggest that the condition of true renal ptosis, demanding or even suggesting nephropexy, is far less common than some authorities would lead us to suppose.

We desire to express our thanks to Dr. A. M. Nussbrecher for his helpful suggestions upon the case of congenital ureteral obstruction, and to Mr. E. Alexander, head technician of the X ray department, Selly Oak Hospital, for his careful preparation of the prints illustrating some of our cases.

NEW SANATORIUM AT BOURNEMOUTH.—Bournemouth town council is considering the provision of a new sanatorium and an option to purchase some 48 acres of land at Canford Magna for this purpose is being secured.

THE USE OF "CAMBRIDGE ELECTRODE JELLY"

By H. B. RUSSELL, M.D., M.R.C.P. Lond.

MEDICAL OFFICER IN CHARGE OF THE CARDIOGRAPHIC
DEPARTMENTS OF ST. THOMAS'S AND THE ROYAL
MASONIC HOSPITALS

It is of great importance, when an electrocardiograph having a string galvanometer is in use, to obtain an efficient electrical connexion between the patient and the machine. The resistance of the string is in the neighbourhood of 3000 ohms; for efficient working the resistance of the patient should not exceed this value and for preference should be considerably less. If the resistance of the patient is high, in order to standardise the machine, the fibre has to be made unduly sensitive; this results in an increase in deflection time and consequent distortion of the electrocardiogram.

The electrodes in common use can be divided into two groups, the "immersion" and the "bound on" varieties. Up to the present, the former have been the more satisfactory, as it has been difficult, when using the latter, consistently to obtain an efficient connexion of low resistance. The use of "Cambridge electrode jelly" seems to be a great advance on anything that has been tried previously; it yields, as

Two electrocardiograms from the same patient (Case 14) showing the results obtained with immersion electrodes and with Cambridge electrode jelly.

will be seen later, results that compare favourably with those given by immersion electrodes—and therefore, it may be assumed, with those given by bound-on electrodes such as "saline pads." It enables electrodes that are much smaller in size than heretofore to be used efficiently. The jelly is sterile, soluble, and colourless, and it has quite an agreeable odour.

Method of application.—No previous preparation of the limbs is necessary. A small portion of jelly—about the size of the finger-nail—is squeezed on to the forearms and left leg and rubbed over an area as large as the electrode that is to be used. The rubbing, which should be quite gentle, is continued for about ten seconds until a faint flush appears on the skin; no irritative after-effects have been noted, even on a skin where varicose eczema was present. The electrode is placed over the prepared area and gently strapped in position; it is only necessary to have this strap sufficiently tight to prevent the electrode from slipping.

*Made by the Cambridge Instrument Co., Ltd., London.

The actual form of electrode is of no great import. The following tests were made with small German silver electrodes, each having an area of a little over 3 sq. in., but other forms do equally well (e.g., Kohn electrode). Actually, the resistance falls slightly with electrodes having a larger area.

Nature of the test.—Twenty-five cases were taken at random; these were the ordinary patients sent to the department for an electrocardiogram. Each case had two tracings taken, one with immersion electrodes and one with electrode jelly, the results being shown in the accompanying Table. The machine used was the trolley type of Cambridge string galvanometer. Before each lead of each electrocardiogram was taken, the machine was carefully standardised to give the usual 30 mm. deflection when an E.M.F. of 3 millivolts was thrown into the circuit. The actual deflection in mm. is given in each case in the following Table: the resistance of the patient can be easily calculated from the following formula. The resistance of the fibre in use was 3100 ohms.

$$R = \left(\frac{R_1}{R_2} \times \frac{R_2}{1} \right) - R_2$$

Where R_1 = deflection of galvanometer without patient connected.

R_2 = deflection of galvanometer with patient connected.

R_3 = resistance of fibre.

No.	Type of electrocardiogram.	Deflection in mm.					
		Jelly.			Immersion.		
		1	2	3	1	2	3
1	T ₁ and T ₂ inverted ..	15	20	15	18	18	18
2	Abnormal Q R S ₂ ..	20	20	18	15	15	15
3	Normal ..	18	18	16	18	18	16
4	Normal ..	20	20	18	16	16	16
5	Auricular flutter ..	17	17	15	17	17	17
6	Normal ..	25	25	25	20	20	20
7	Auricular fibrillation: notched R ₂ ..	20	20	20	14	14	14
8	Normal ..	20	20	20	20	20	20
9	Normal ..	21	21	21	15	15	15
10	Displacement of R-T ₁ & ..	20	20	20	15	15	15
11	Normal ..	22	22	22	20	20	20

14	L. axis deviation ..	20	20	20	17	15	15
15	Normal ..	20	22	20	18	18	18
16	Normal ..	20	20	20	20	20	20
17	Auricular fibrillation ..	22	22	22	18	16	16
18	Bundle branch block ..	20	20	20	20	20	20
19	Coronary thrombosis type ..	20	20	20	15	17	15
20	Paroxysmal tachycardia ..	18	18	18	15	15	15
21	Auricular fibrillation ..	22	22	22	20	20	20
22	R ₂ notched ..	22	20	20	18	18	18
23	Normal ..	18	18	16	18	18	16
24	Auricular fibrillation ..	18	18	18	20	20	20
25	Normal ..	20	20	20	15	17	15

It will be noticed that the jelly connexion gave a lower resistance in 16 cases (64 per cent.); in 5 cases (20 per cent.) the resistance was the same as with the immersion electrodes, while in the remaining 4 cases (16 per cent.) the resistance was higher. In many instances the connexion whilst using the jelly was greatly superior and in none was it inferior to any material extent.

There are, however, many other advantages to be gained by the use of the jelly. In the first place, it does not matter whether the patient is sitting or lying down; with immersion electrodes the former position is practically essential. Secondly, somatic tremor is almost always much reduced. The Figure illustrates this point. Thirdly, it is not necessary for the patient to keep so still; I have taken a perfectly satisfactory "lead I." from my assistant whilst he was walking slowly about the room! Talking has practically no effect on the fibre. At no time was

any sign of polarisation evident (as shown by "wandering" of the fibre).

One disadvantage of immersion electrodes is a tendency to spill saline or possibly zinc sulphate solution on the surrounding floor, an accident which may interfere with effective insulation of the patient. No such trouble is experienced when jelly is used. For use on bed cases, too, the absence of liquid solution has obvious advantages. Another minor advantage of the jelly over the "pots" is that it is unnecessary for the patient to remove his boot.

Immersion electrodes are ugly, and if they are unnecessary their removal is doubtless an advantage. The introduction of electrode jelly as a substitute is a useful contribution to electrocardiography.

Clinical and Laboratory Notes

DOUBLE PYOSALPINX DUE TO SALMONELLA NEWPORT INFECTION

By DOROTHY BROWN, M.B. Sheff.

LECTURER IN BACTERIOLOGY IN THE UNIVERSITY OF SHEFFIELD

THE patient, a married woman of 26, had had no children and no abortions. There was no history of severe illness.

Present Illness.—She first felt ill on Dec. 1st, 1930, her symptoms being backache and attacks of slight shivering. These continued for four days, but were not severe enough to prevent her working. On Dec. 5th she was seen by her own doctor and was found to have pyrexia and slight tenderness in the lower abdomen, then attributed to the onset of menstruation. She remained in bed but the symptoms continued, and after about 18 days a definitely tender area was apparent in the lower abdomen. She was therefore transferred to the Jessop Hospital for Women, Sheffield.

On admission (Dec. 22nd) she had a temperature of 101.6° F. and a pulse-rate of 128. A tender area was found just above the brim of the pelvis, the tenderness being greater to the left of the midline and extending to the left iliac fossa. Per vaginam, a hard, immobile swelling was found in the pouch of Douglas.

At operation on Dec. 30th a large left pyosalpinx and a smaller right pyosalpinx were found and drained. As clinically the condition appeared tuberculous, some of the pus was sent to the laboratory for bacteriological examination and guinea-pig inoculation. During the 17 days immediately following the operation the temperature and pulse gradually returned to normal. She went home on Jan. 30th with only very slight discharge and feeling well. Throughout her illness she never experienced headache, acute abdominal pain, diarrhoea, constipation, nausea, or vomiting; the backache, abdominal tenderness, and pyrexia were her only symptoms.

EXAMINATION OF PUS

(a) A direct film preparation showed the presence of numerous pus cells and Gram-negative bacilli.

(b) On culture a pure growth of a motile Gram-negative bacillus was obtained. It fermented glucose, maltose, mannitol, dextrin, and xylose with the production of acid and gas. It had no action on lactose, saccharose, adonitol, inositol, or inulin. The Voges-Proskauer reaction was negative, and there was no indole production. Litmus milk was turned faintly acid then alkaline.

In order to identify the organism agglutination tests were performed with Oxford standard specific agglutinating sera for *Salmonella paratyphi* A, *S. paratyphi* B, *S. enteritidis* Gaertner, *S. aertrycke*, and *S. newport*; but it was not agglutinated by any of these. The bacillus was therefore subcultured daily in broth, and after three

weeks it was found to be agglutinated by *S. newport* (H.sp.) serum in dilutions of from 1/25 to 1/250.

(c) A portion of untreated pus was inoculated subcutaneously into two guinea-pigs. Both animals developed an abscess at the site of inoculation in the course of a week to ten days, and from the pus a pure growth of a bacillus corresponding in every respect with the original organism was obtained. A portion of pus treated by the antiformin method was inoculated subcutaneously into two guinea-pigs. These developed no local lesion, nor did they show any evidence of tuberculosis when killed six weeks later.

AGGLUTINATION TEST

As soon as it was realised that the causal organism was probably of the salmonella group, agglutination tests were performed with the patient's serum (Jan. 6th). No agglutination of Oxford standard agglutinable cultures of *S. typhi*, *S. paratyphi* A, *S. paratyphi* B, *S. enteritidis* Gaertner, or *S. aertrycke* occurred in any dilution, but *S. newport* was agglutinated in dilutions of from 1/25 to 1/500. A second series of agglutination tests performed on Jan. 29th showed that the titre for *S. newport* had fallen to 1/250.

ANTIGENIC ANALYSIS

It was concluded from the above that the organism was a *Salmonella newport* and agglutinin-absorption tests were therefore performed to confirm this.

A. Specific Phase.—Specific phase emulsions and sera (rabbits') were prepared from the strain 2703 (isolated from the patient) and from strains of *S. newport* and *S. reading*. Each of the three sera was absorbed separately with each organism, and in every case the specific agglutinins were entirely removed.

The original titre of each specific serum was 1/10,000.

B. Non-specific Phase.—Non-specific phase emulsions and sera (rabbits') were prepared from strain 2703 and from strains of *S. newport* and *S. aertrycke*, and reciprocal agglutination and agglutinin-absorption tests were performed. The accompanying Table shows the results.

Results of Agglutinin-absorption Tests

Non-specific serum.	Emulsion.	Original titre.	Percentage absorption after absorption with—		
			2703 non-specific.	Newport non-specific.	Aertrycke non-specific.
2703	2703	1/10,000	100.0	87.5	95.0
	Newport	1/2,500	100.0	100.0	100.0
	Aertrycke	1/2,500	100.0	100.0	100.0
Newport	2703	1/10,000	100.0	100.0	100.0
	Newport	1/50,000	97.5	100.0	100.0
	Aertrycke	1/50,000	95.0	100.0	97.5
Aertrycke	2703	1/2,500	100.0	100.0	100.0
	Newport	1/20,000	75.0	100.0	100.0
	Aertrycke	1/20,000	87.5	97.5	100.0

In the case of both the specific and non-specific phase the emulsions were prepared from colonies selected as described by Bruce White.¹

C. Somatic Phase.—Somatic emulsions and sera (rabbits') were prepared from strain 2703, and from strains of *S. newport* and *S. moribificans-bovis*. Reciprocal agglutination and agglutinin-absorption tests were performed with these. In the case of each serum the somatic agglutinins were entirely removed by absorption with each of the organisms.

The original titres of the sera were 1/1000 in the case of strains 2703 and *S. moribificans-bovis*, and 1/500 in the case of the *S. newport* strain.

The emulsions were prepared by growing the organisms on phenol-agar and then treating them with alcohol as described by Muir and Ritchie.²

Discussion of Results of Antigenic Analysis.—The specific phase of strain 2703 was proved to be identical with that of the strains *S. newport* and *S. reading* = D₁D₂ (Bruce White's classification). The non-specific phase showed a slight difference from that of *S. newport* and *S. aertrycke*. There was apparently a minor factor present in 2703 not found in the others, and, on

the other hand, in the non-specific phase of both *S. newport* and *S. aertrycke* there appears to be some antigenic fraction which is not present in the strain 2703. The somatic antigen was shown to be identical with that of *S. newport* and *S. moribificans-bovis* = IV. (Bruce White's classification).

OTHER INVESTIGATIONS

A blood sample was taken for culture but was found to be sterile, as was to be expected so late as the fifth week of illness.

Specimens of faeces and urine were cultured but no organism of the salmonella group could be recovered from them.

The source of infection could not be traced. The patient helped her husband in a sweet and tobacco business and they had no assistants. She did all the housework and cooking herself. They rarely visited others or received visitors. They could not recollect sharing a meal with any other person for some weeks previously. The husband was apparently healthy. He had had no serious illness nor could he recollect even slight indisposition during the last few months. Agglutination tests performed with his blood-serum against the chief members of the salmonella and dysentery groups proved entirely negative.

This case is of interest in that, as far as I know, it is the only recorded case of abscess-formation due to *Salmonella newport*.*

I am indebted to the late Mr. W. W. King for the clinical history of this case.

INTUSSUSCEPTION DUE TO INVAGINATION OF A MECKEL'S DIVERTICULUM

BY GORDON DUNCAN, M.B. Lond.

ACTING MEDICAL OFFICER, HILLINGDON COUNTY HOSPITAL, MIDDLESEX

A BOY, aged 9 years, was admitted to hospital complaining of abdominal pain of five days' duration. The pain was generalised and colicky, and he was said to have had a similar but less severe attack five weeks previously. At the onset, five days before admission, he had vomited once, and he vomited bile-stained material on arriving in the ward. His bowels were open the day before admission and there was no history of passage of blood per rectum.

On examination a tender mass, both visible and palpable, was found filling the right iliac fossa. A diagnosis of appendix abscess was made and Ochsner-Sherren treatment adopted. Twelve hours later the mass had shifted to the midline and the patient's condition was worse. The abdomen was opened by a right paramedian incision and an ileo-ileal intussusception was found. Reduction was fairly easily performed, but about 12 inches of gut, comprising the intussusceptum, was gangrenous and the intussusciens was plum-coloured but viable. A Meckel's diverticulum, 3 inches long, was found invaginated into the lumen of the bowel and formed the apex of the intussusception. The patient was considered to be too ill to stand resection, so the ileum above and below the affected gut was brought together and lateral anastomosis was performed.

* The strains of *S. newport*, *S. aertrycke*, *S. reading*, and *S. moribificans-bovis* used were obtained from the National Collection of Type Cultures. They were as follows: *S. newport*, No. 129 (Newport); *S. aertrycke*, No. 74 (Mutton); *S. reading*, No. 72 (Reading); *S. moribificans-bovis*, No. 2215.

The gangrenous loop was left out of the abdomen and the wound partially closed. On the third morning after operation the bowels acted well and the patient's general condition was good. On the fifth day the gangrenous gut was resected and the bowel ends closed. A corrugated rubber drain was inserted and the wound closed. The patient is now convalescent.

I am indebted to Dr. W. A. Steel, medical superintendent, Hillingdon County Hospital, for permission to publish this case.

TORSION OF THE SPLEEN

ASSOCIATED WITH RUPTURE

By Y. CANTIN, M.R.C.S. Eng.

MEDICAL SUPERINTENDENT OF THE CIVIL HOSPITAL, PORT LOUIS, MAURITIUS

TORSION of the spleen as a cause of the "acute abdomen" is hardly a surgical rarity, especially in the tropics, where enlarged and mobile spleens are common. The following case is remarkable, however, because torsion was associated with rupture and intraperitoneal hæmorrhage.

The patient, aged 50, was referred to us on May 22nd, 1934, from a mental hospital. She had fallen ill on the 20th, when she complained of colic; her bowels had not been opened for two days and the pulse-rate was 132. Nothing abnormal could be found in the abdomen and she was given an enema with a good result. On the 21st her temperature was 100° F., she had rigors, vomited twice, still complained of abdominal pain, and had a pulse-rate of 150. An enema was given on the 22nd with poor result, and when the patient was admitted to the Civil Hospital on that day her condition was as follows: Temp., 100.4° F.; pulse 120, fairly full; tongue furred but moist; features rather drawn. Abdomen moves well with respiration. No distension. No visible peristalsis. A swelling could be made out in the umbilical region, but careful palpation was impossible as the patient was restless and wanted to be left in peace. Vaginal examination revealed some fullness and tenderness in the pouch of Douglas.

Although the exact diagnosis was in doubt operation seemed essential. When the patient was under the anæsthetic, abdominal palpation revealed a firm, mobile, central swelling stretching across the umbilical region towards the right; the right iliac fossa felt quite normal. A right paramedian subumbilical incision was made and as soon as peritoneum was nicked blood welled out of the abdomen; about ten ounces was, by means of a rubber tube, collected into sodium citrate solution for subsequent transfusion into the patient. The peritoneal incision was then enlarged in an upward direction, and the spleen came into view, with a fissure about two inches long and a quarter of an inch deep over its convex surface. Well-marked plastic peritonitis was present, and the organ was adherent to neighbouring intestinal coils and to the large omentum. The adhesions were easily separated and the spleen, which was about four times the normal size, was easily exposed. Its pedicle was then found to be twisted through three and a half turns in a counter-clockwise direction. Splenectomy was performed in the usual way; the splenic vessels were thrombosed, and the spleen itself acutely congested. Whilst clearing the pelvis from blood clot, an ovarian cyst, about the size of a tangerine orange, was discovered on the left side and easily removed. The abdomen was closed without drainage and the patient made an uneventful recovery.

What was the mechanism of the rupture? An infarcted spleen may rupture spontaneously or from slight violence. In reporting a case, Collins Warren¹ writes: "It would seem highly probable that dis-

tension of the capsule nearly to the bursting point by the cutting off of the egress of the blood by thrombosis of the splenic vein had prepared the way for rupture of the capsule by slight violence." As our patient was non compos mentis, self-inflicted injury cannot be ruled out altogether. It is also conceivable that disorderly movements on her part may have caused the rupture of her very much enlarged and mobile spleen, and at the same time initiated the torsion which in its turn arrested the hæmorrhage by occluding the vessels in the pedicle. It seems however more reasonable to suppose that the rupture was spontaneous and that, as not infrequently occurs in twisted ovarian cysts, the torsion was at first sufficient to occlude the thinner-walled splenic vein but not the splenic artery, which continued for some time to irrigate the organ, with resultant acute congestion and finally rupture.

DEATH FOLLOWING PERFORATION OF STERCORACEOUS ULCER

By J. J. O'REILLY, M.B. Belf., D.P.M.

DEPUTY MEDICAL SUPERINTENDENT, WINSON GREEN MENTAL HOSPITAL, BIRMINGHAM

THE patient, a man aged 49, had been admitted to the City of Birmingham Mental Hospital, Winson Green, in 1931. Apart from a large right scrotal hernia and evidence of fatty heart disease, he had enjoyed comparatively good health, and he made no complaint of physical illness until April 29th, 1935.

On that day he complained of vague pain in the upper abdomen. Physical examination revealed slight diffuse tenderness over this area but no other signs. He was unable to retain any food and vomited even after sips of water and milk. His urinary output averaged 16 oz. in the 24 hours but the urine contained no abnormal constituents. His temperature remained subnormal throughout the illness, but his pulse-rate became progressively more rapid and feeble—from 84 at the onset of illness to 114 at the time of death. Two days after the onset of his illness his abdomen became much distended and on the suggestion of the consultant surgeon to the hospital, who considered the condition to be one of paralytic ileus, he was given pituitrin followed by turpentine enemata but without effect.

He died on May 3rd and post-mortem examination showed free gas in peritoneal cavity with a small quantity of semi-solid faeces lying in the neighbourhood of the lower border of the omentum. The large intestine was enormously dilated and filled with faecal masses from the cæcum as far as the middle of the transverse colon. At the latter point there were three small perforations in the bowel wall. On the inner aspect of the bowel at this point there was a stercoral ulcer about 4 in. long lying in the long axis of the intestine.

It is of interest to note that the ulcerated condition, which must have been present for some considerable time, gave rise to no symptoms until within a week of death, and even then there were no signs indicative of the grave condition underlying the illness.

I am indebted to the medical superintendent, Dr. C. W. Forsyth, for permission to publish the details of this case.

ACTON HOSPITAL.—The first stone of the extension to this institution has been laid by the Mayor of Acton. The new building, which is to cost over £18,000, will include a men's ward and an enlargement of the out-patients' department.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTIONS OF EPIDEMIOLOGY AND
TROPICAL DISEASES

At a joint meeting of these sections held on Nov. 16th the chair was taken by Surg.-Captain SHELDON DUDLEY, president of the section of epidemiology, and a discussion on the

Malaria Epidemic in Ceylon

was opened by Sir WELDON DALRYMPLE-CHAMPNEYS. He began with a warm tribute to the work of his co-author, Dr. R. Briercliffe, director of medical services in Ceylon, who was unable to be present owing to a recrudescence of the outbreak. Epidemic malaria, he continued, had received little attention in the island until last year, for attention had been concentrated on the endemic form. Ceylon was shaped rather like a sheep's skull standing on its occiput. The south-west quadrant was the "wet" zone and was normally free from endemic malaria, but had been particularly affected by the 1934-35 epidemic. This was the richest, healthiest, and most populous part of the island, and received both south-west and north-east monsoons. The remaining three-quarters received rain mostly in the early autumn and was relatively dry. In 1934 from April onwards the south-west monsoon had partly failed, and the unprecedented drought had provided ideal breeding-places for the mosquito. It was a remarkable fact that the *Anopheles culicifacies* was the only species proved to be a malaria-carrier in Ceylon. In the upper and middle reaches of the rivers the flow had been reduced to a mere trickle, allowing the formation of many rocky and sandy pools. *A. culicifacies* chose just such clear unshaded pools for its eggs; shallow wells, pools in quarries and brickpits were subsidiary breeding-places. Its natural home was in the dry zone, and it was not found much in the wet zone until the abnormal drought produced dry zone-like conditions in the wet zone. The adult male was not easy to find, but it had been collected in unprecedented numbers during the epidemic period. There was no lack of gametocyte carriers, since in any year an average of 400,000 persons sought treatment at government centres.

The epidemic had broken out in four river basins on the west of the watershed and one on the east. The villages first and worst affected were on the banks of the rivers and the epidemic involved nearly a quarter of the island's area and nearly half its people: an area of 5800 square miles with a population of 3,100,000. Provincial surgeons had been warned to expect malaria, but the sudden overwhelming outbreak had been unanticipated and unprecedented. The first characteristic was the explosive feature; epidemics usually spread gradually. The chart of weekly attendances at the dispensaries showed a sharp rise, and peak at Dec. 22nd (62,000 attendances) with a more gradual fall. From the end of January numbers declined until a secondary wave appeared in April. It was estimated that a million and a half people contracted malaria between October, 1934, and April, 1935, and over 95,000 died. There was an excess of deaths (over 37,000) in the non-epidemic area also. The secondary wave had not been unexpected and it had affected all the five river valleys. The great epidemic had differed from others in

starting in October instead of April. The failure of the south-west monsoon had been followed by a weak north-east monsoon. During the secondary wave many people and villages hitherto unaffected had fallen victims, but the most interesting extension had been upwards. Before April, malaria above 2000 feet had been uncommon, and above 2500 very, very rare; during this wave cases had occurred at 3500 feet, *A. culicifacies* being found there both in larval and adult form. The cases had been less severe and mortality lower in this wave, everywhere except in the Kandy district. Since June there had been steady improvement. The deaths had been down to the expected figure in most districts by September.

Antilarval measures had been started in January, 1935, and consisted of canalisation and oiling of breeding-places. Seven thousand miles of water-course, much of it through thick jungle, would have had to be covered if the whole range of breeding-places had been dealt with; an average worker could only cover a mile and a half a day. Emergency regulations had been issued in February. Elephants had been useful for clearing obstructions. Most cases were of the simple febrile type, responding readily to treatment. Relapses had been frequent because patients had discontinued treatment as soon as symptoms disappeared. There had been only five cases of blackwater fever. Deaths had mostly been due to dysentery and pneumonia. Post-malarial oedema had been regarded as a nutritional phenomenon, and feeding had been arranged for children in schools. Gangrene of the extremities had been seen occasionally. The most important antimalarial measure had been treatment of patients by quinine grs. $7\frac{1}{2}$ thrice daily in solution. This was regarded as safe in unqualified hands, but Plasmoquine and Atebrin were used only in hospitals. Treatment centres had been opened in all badly affected villages. A total of 690 hospitals and 38 temporary hospitals had been opened in addition to the 80 central dispensaries, and 136 estate dispensaries had been supplied with quinine by the government. Over 33,000 lb. of quinine had been served out, and there had never been any shortage. No patient had had to go more than a mile and a half for treatment. There had been in-patient accommodation for 5000 cases, congestion being most acute in February.

Dr. V. B. WIGGLESWORTH said that many factors were at work in the genesis of a malaria epidemic. The appropriate mosquito was, however, a sine qua non. *A. culicifacies* occurred throughout the whole island. In the tea gardens of Assam it was uncommon during the monsoon, which continually flushed the rivers. In the dry season, on the other hand, it was found in myriads in the clear water pools; but because this was the dry season there was no infection. Similar conditions occurred in the hills of Southern India, and other species carried malaria in these parts. In the Punjab *A. culicifacies* found suitable breeding-places every year, and the neighbouring villages were centres of endemic malaria. They had much in common with the endemic areas of Ceylon. In years of excessive rainfall wide tracts of the Punjab became infested, and if the people had lost their immunity great epidemics resulted. The most striking difference was that breeding was favoured by excessive rainfall in the Punjab and by excessive drought in Ceylon and Madras. Given

good organisation, the large towns ought to be able to protect themselves, but antimosquito measures were least hopeful in rural areas where *A. culicifacies* was the carrier. In Malaya good agriculture needed clean drains, and this eliminated the two most dangerous mosquito species. Along these lines lay the best hope for the rural area: the modification of agricultural practice in such a way as to eliminate the mosquito. Unfortunately the abundance of *A. culicifacies* in Ceylon bore little relation to agriculture. The pools were a natural phenomenon and larvae were continually being carried down stream. Nothing in existing experience in the world could give confidence in antimalarial measures for such an area as that involved in the Ceylon epidemic. A great deal more knowledge about the mosquito and its ways was needed: the criteria on which it selected its breeding-places and its choice between man and animals; the extent to which females remained in houses, and such matters. The best hope lay in an intimate study of the bionomics of *A. culicifacies*.

Dr. P. H. MANSON-BAHR said that during the years 1912-13, when he had been in Ceylon, malaria had been the scourge of the low country: the humid, hot, agricultural western and southern districts, and the hot, dry jungles of the north and east. At that time there had been no evidence of primary infections above 2200 feet, although history recorded epidemics above that level in Kandy as well as enormous ravages in the north, central and eastern provinces. The great cities of Anurhadhapura and Polonnaruwa, seats of the Sinhalese kings, were thought to have been abandoned because of malaria. Dr. Manson-Bahr had studied representative series of blood films from all over the island and concluded that the quartan parasite predominated (64 per cent.) and benign tertian next (19 per cent.), the most infrequent being the subtertian (17 per cent.). In those days tanks and ricefields had not been regarded as the main breeding-centres; the mosquito had been found much more abundantly in irrigation streams and the locomotive water-supply troughs beside the railway.

Colonel C. A. GILL added his tribute to Dr. Briercliffe and the Ceylon medical department and emphasised the salient features of the scheme adopted. As soon as the explosion had occurred steps had immediately been taken to mobilise the whole medical resources of Ceylon. Every practitioner, dispenser, sanitary inspector, and student had been enlisted to deal with the emergency. The public health department personnel of all kinds was at once switched over to help the medical department. This brought out the importance of having one head of both medical and public health departments. The next remarkable thing was the sudden expansion of hospital facilities by erecting new temporary buildings and by adapting schools. Branch dispensaries had been turned into central dispensaries, and beyond them had been treatment centres always open, and sub-treatment centres occasionally open. All serious cases had been drafted at once to properly equipped hospitals. Free kitchens had been opened at the dispensaries because the people were suffering from famine as well as malaria, and milk products had been freely available for undernourished children. The sanitary inspectors had been utilised very largely as intelligence officers and quinine distributors in the villages. Weekly reports had been received from every centre, and departmental conferences had been held whenever necessary. The epidemic had attracted a remarkable amount of public attention and some

most unjustifiable criticism had been published. It was the first great malaria epidemic of modern times in the tropics, only paralleled by the Mauritius outbreak of 1867. Previous epidemics had been associated with excessive rainfall and had had only one wave of mortality. The Ceylon epidemic had therefore presented some extremely interesting epidemiological features.

Prof. W. SCHULEMANN said that in the emergency well-tried routine methods had naturally been used, and there had been no time to try new methods and make detailed observations. He discussed the intravenous use of quinine and atebirin. He agreed with the use of atebirin only in hospitals in Ceylon, but thought that this drug would prove to have many advantages owing to its better and more rapid absorption and action. He was sorry that it had rather been pushed into the background. It destroyed the gametocytes to such an extent that they were no longer able to infect mosquitoes, and reduced the relapse rate.

Colonel S. P. JAMES discussed the interaction of the various aetiological agents, and especially the rather puzzling subject of the influence of a non-immune population on the extent of the epidemic. Before the change of climatic conditions the population at risk had had no immunity to malaria. Laboratory work had shown that in non-immune patients the gametocytes occurred in the blood in much greater numbers and so an anopheles got its stomach absolutely crammed with oöcysts after a single feed. After feeding on an immune patient there might be two or three or at most ten oöcysts in the stomach. The mosquito which had taken several hundred oöcysts into its stomach would contain enough oöcysts to infect thirty or forty people, and remained infective for three or four months. The mosquito with only three or four oöcysts in its stomach lost all its oöcysts in biting one person and was infective for only two or three days.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION

A MEETING of this association held in London on Nov. 15th, with Dr. G. E. FRIEND (Christ's Hospital) in the chair, was devoted to

Problems of the Medical Officer in Private Preparatory Schools

Mr. E. WILSON HALL (Eastbourne) said he would approach the subject as a general practitioner, since he and his partner were looked upon as school doctors to 15 private schools. At some of these the doctor chosen by the headmaster or the headmistress was the only one allowed in the school, whereas in others he had known as many as four doctors attending pupils even during the same epidemic. In such circumstances a friendly relationship with colleagues and a strict ethical code were essential. He asked that he might be notified of any infectious disease which started in another doctor's patient, and that all question of infectivity and disinfection should be left to his decision. He welcomed the access of pupils' doctors to his schools, because it allowed of continuation of treatment and general care. But where the child came from outside the town and had no local general practitioner, it was unwise, and not exactly courteous, to ignore the school medical officer and write privately to another practitioner in the town asking his services. A recent case in point

was one in which a child, aged 14½, whom the speaker had looked after for eighteen months, was taken by the parents to a specialist because of an excess of body-weight. Her periods were scanty, and exercise made her short of breath—a common state of affairs, which usually rectified itself in a year or so. That girl was returned to school with instructions to a doctor in the town, who had never seen her, to give her thyroid, let her play no games, and diet her. Mr. Hall also had a word of condemnation of the custom, all too prevalent, of matrons serving out patent medicines sent back with the children by their parents. Most of the children were quite healthy, and this taking of vitamin-containing and other concentrated medicines could not be good for them; nor was the emphasis that was placed on their health. In private schools the doctor had to tread very warily, for he did not want to risk the child's removal from the school. In one or two essentials, however, he must look after the majority and advise the school authority to lose one or more pupils if necessary. In such diseases as scarlet fever, scabies, impetigo, and ringworm of body or scalp he usually allowed a longer period to elapse before permitting return to school than did most of his colleagues; the responsibility for other people's children was a very heavy one. Many parents went abroad leaving their children in charge of relatives or (as he considered preferable) the school authorities with full responsibility. If parents were really satisfied with the school and had met the medical officer, much loss of time could be avoided by dispensing with their permission before operating on appendicitis, otitis media, or similarly urgent conditions.

Certain rules the speaker found useful in dealing with the school matron; for example, any child with a rash was isolated, and no aperient was given in a case of abdominal pain, until after a medical visit. There must be no failure to call the medical officer wherever there was doubt or anxiety. In several of his schools Mr. Hall had instituted examination of each child at the beginning and end of each term, being informed by the matron of any loss or gain in weight. Regular weighing was very important, and provided a ready answer to parental criticism of the school food. He had been surprised at the number of requests received from parents that their children should not be allowed to play certain specified games. In private schools all the games were very well regulated, and even slight over-fatigue was readily noticed. His only criticism on this head was that the sports curriculum was rather too full, it did not allow enough leisure. He greatly favoured all team games; but running must be kept well within the fatigue limit in the developing child, and the preparatory schools he attended no longer held half-mile races. Sea-swimming was very valuable, but the responsibility of taking a crowd of children into the open sea was usually held to be too great, and most of the schools went to the sea-water baths. The swimming season, almost entirely from the baths, produced yearly many cases of otitis media. Though a pre-existing nasal infection was often the cause, and children with any such infection should be kept from bathing, he thought it unwise to encourage high diving, or frequent diving-in and coming out. He had prevented many a middle-ear infection by the use of 20 per cent. Argylol drops up each nostril thrice daily. He was decidedly in favour of inoculation against the common cold and influenza, and had carried it out in several schools for some years. During an attack he again used the argylol drops.

The CHAIRMAN said his experience was that parents nowadays were more apt to complain than they were a few years ago. But once they had been to the school and had an interview with the housemaster and the doctor, complaints largely ceased. The number of patent medicines brought back by boys to school almost constituted a public danger.

The Rev. W. R. MILLS, as headmaster of a large preparatory school, said he could not understand why the modern parent seemed to have so little faith in medicine except when administered by the home doctor. The school doctor had to be a person of extraordinary persuasiveness and strength of personality. It was always a regret to him to see disloyalty on the part of the home doctor to the school medical officer, and to an outsider it seemed a case in which the medical etiquette might beneficially be stiffened up.

Dr. G. H. BICKMORE spoke as a headmaster with a medical training, and said that in his school a health and hygiene committee had been set up to make recommendations concerning all health matters. That body considered that the danger of setting up middle-ear disease in bathing was greater from jumping-in than from ordinary diving. In some schools boys under eight were allowed to participate in cross-country running of half a mile. Wolf-cub sports, also, were often too exhausting for the younger boys. Many medical authorities considered that 100 yards should be the limit race distance for boys under eleven; some said 60 yards, and with the latter he agreed. He was not impressed with the value of inoculation against colds; he set more store by hygienic conduct and the disinfection of clothes.

Dr. GRAHAM FORBES agreed that jumping into the water was liable to drive infected mucus into the Eustachian tube. He did not think cases of otitis media occurred often enough in users of swimming baths to justify the disease being attributed to the swimming. As to running, he agreed that the boy of eight years should not be required to do more than 100 yards, but the born runner might suffer no harm from running longer distances.

Dr. W. ATTLEE (Eton College) said there was always an element of suspicion on the part of the parents as to the medical arrangements of the school. That was due to the two reasons which Mr. Hall had mentioned: (1) that often the doctor never saw the parents at all, and so was acting without any knowledge of them; and (2) that the school doctor could not treat children in the same way as they were treated in their own homes; at home minor risks could be taken which could not be taken at schools. Matrons and doctors at schools were always buffers between the children and their homes, and the interests of the boy were often at variance with those of the school and of the school doctor. If masters would realise, as Mr. Mills did, the difficulty of doctoring boys in school, they would encourage meetings between doctors and parents, and then, he felt, unpleasantness would vanish. With regard to athletics, he thought a boy under twenty was unlikely to damage himself by over-exertion; he had not the will power to drive himself to that extent. It was a different matter if there had recently been an exhausting illness.

Mr. A. E. LYNAM said he was himself especially keen on prevention, and would welcome advice from the Association on this head. When a child was likely to need an operation he thought the parents ought always to be consulted. The matron was

often given too much power, and she needed to be looked after. The headmaster should ask the advice of the doctor on medical matters, and the matron should carry out instructions.

Dr. R. E. SMITH (Rugby School) spoke of the steadily decreasing death-rates following on the more routine performance of necessary operations—e.g., for acute appendicitis. It was now the rarest occurrence for a boy operated upon for appendicitis to die. As to acute mastoid disease, this tested judgment more than any other condition met with in school work. He had had only one case of it at Rugby in the last five years. Many tender mastoids did not need opening, and mere earache without bulging and a definite rise of temperature did not call for operation. Prevention was largely a matter of efficient ventilation, and many preparatory schools were altered private houses. His view was that the sooner the population of the schools had the childhood infectious diseases the better for them, as they were in a condition to stand them better when young, and acquired a gradual immunity which lessened the total incidence of the serious disease.

Dr. J. LAMBERT (Wellington College) hoped it was realised that school doctors made determined efforts to get at the root foundations of diseases and the methods of their spread. Dormitories alone could not be blamed; boys mixed at games, in the library, and especially in the school chapel, and they did not take kindly to advice on personal hygiene. The school had to be regarded as a closed community. When boys with measles and influenza were warned of the danger of blowing their noses too hard, or of coughing vigorously, and were put on to inhalations of menthol or eucalytus, the ear complications at Wellington fell much below what was regarded as the average in other schools; he was surprised if he saw more than one mastoid case in two years. He did not practise early drum puncture for ear trouble; ensuring drainage would often result in quick subsidence. Much depended on the anatomical conformation of the particular ear.

Dr. J. A. H. BRINCKER said that in discussions on ear trouble following swimming it was assumed that the ears were normal, but many children had conditions that predisposed to otitis. In the absence of statistics no pronouncement on this danger was reliable. The type of school doctor which the Association was trying to develop was the one who would be of the greatest use to both pupil and headmaster. In past times the tendency had been too much in the direction of allowing the matron to decide when to send for the doctor. He reminded Mr. Lynam that the prevention of disease was a very difficult and complicated matter, and that the introduction of fresh individuals into the particular community might perpetuate an epidemic, however thorough were the measures taken.

NORTH-WESTERN TUBERCULOSIS ASSOCIATION

IN the course of a presidential address to this association in Manchester on Oct. 31st, Dr. PETER W. EDWARDS dealt with certain points he had found of definite value in the

Treatment of Adults Suffering from Pulmonary Tuberculosis

The days of super-alimentation had, he said, gone in the sanatoriums; but mothers, nurses, and some

doctors still thought it necessary to overburden the impoverished stomach and if over feeding at recognised meal-times was impossible there was a sequence of snacks. Patients arriving at a sanatorium were a sorry demonstration of the result of this routine. Three ample meals of a good all-round diet containing fats and salads sufficed and the patient's stomach wanted rest before, after, and between meals, particularly before. In winter a teaspoonful of cod-liver oil once a day was probably beneficial.

Much had been written about air, and unfortunate patients who should be in bed were encouraged to seek air in parks and there, muffled up, they sought air for their lungs denying it to the body and wearying themselves withall. At the sanatorium protection from the elements was encouraged, for it was never clear why a patient with feeble lungs could tolerate fierce elemental conditions. But this protection did not mean coddling or muffling. The body surface and not merely the patient's face wanted the air. It was somewhat devitalising and dangerous to have patients snug in bed—Central African conditions of warm humidity and stillness under the bedclothes and his face in good British climate. The patients should get accustomed to the minimum of bedclothes and it was possible in all months even in England to get rid of blankets, especially for an air-bath. Such patients on absolute rest might keep up good body tone. Akin to this was exposure to sun and this was encouraged not because of faith in the value of the sun's rays but because of the value of moving air. Properly conducted, sun exposure did no harm. Because of this faith patients should be out early in the day in all seasons and protected around mid-day in summer. In the grading of patients their first move from bed-grade should be "up from 7 to 9 A.M."

GENERAL REST

Rest was the chief treatment and no rest was as good as that obtained on the bed. Patients should be encouraged when back at work to return home to rest on their beds and away from the home folk who encouraged talking: surely talking was mighty hard work for damaged lungs. For a few years after leaving the sanatorium patients should retire by 8 P.M. and get up at 7 A.M. This long night was a fine tonic. Bed rest should be accompanied by silence; this combination gave general and local rest. He encouraged the use of sand bags, up to 9 lb. in weight on each side of the chest. This, in addition to increasing rest, gave the patient something to do—a fact of importance. Results of this treatment at the sanatorium in acute cases were usually astonishing.

Frank pulmonary tuberculosis of any severity was rarely improved by tuberculin. Certain proliferative cases benefited and it was estimated that 2 per cent. of patients at the Cheshire Joint Sanatorium were always treated by tuberculin. Sanoerysin and certain other gold preparations had proved of value, particularly in exudative cases and in recent spreads in the opposite lung in artificial pneumothorax.

In laryngeal tuberculosis, strict voice rest, granted the lungs were healing, seemed to be all that was necessary. For extreme pain the injection of alcohol into the superior laryngeal gave temporary relief and the removal of the nerve gave permanent relief. It was possible to do this bilaterally if an interval of some six weeks was allowed. Feeding by means of a stomach-tube was better than slow starvation,

and this method should be adopted if there was any hope. The actual cautery had a very limited sphere and ultra-violet radiation locally probably none at all. The treatment was control of the lung, general exposure to air, and voice rest.

A development of note in treatment had been the colony. The spirit of enterprise and hope, the absence of the rush of ordinary industry coupled with the knowledge that medical observation was direct and regular produced good results. The colony—a place for prolonged treatment for some, for training for others, and possibly permanent settlement—had not been appreciated as yet by the community. The cottage scheme introduced by Dr. Dan Powell for the training of patients in domestic sciences was an excellent advance; it could and should be available in all sanatoriums for females.

LOCAL REST

Efficient strapping was rarely seen and yet strapping properly applied was comfortable and brought a large measure of rest. It was as valuable in one-sided disease as it was in pleurisy.

Artificial pneumothorax was the greatest development in treatment and the day had come when it should be applied more generally. It was to be preferred over all other methods; it was available for one-sided cases and for bilateral cases, consecutively or simultaneously. It was poor practice to carry out artificial pneumothorax treatment without X ray control and film control was only half control. The fluoroscopic screen was the method of choice. Watch the diaphragm, it might be depressed, and look for fluid. Watch the opposite lung as disease sometimes spread rapidly. Watch the mediastinum for flop and hernia as the film would not usually show this. See if the collapse was hindered by adhesions and, if the screen did not give details, take a film of the hemithorax in expiration when the character of the collapse was in doubt and an ordinary film where there was suspicion about the contralateral. All artificial pneumothorax cases needed an X ray photograph as a routine at least every twelve weeks.

Do not aim at compression in artificial pneumothorax, for healing occurred with relaxation and small peripheral collapse. Usually cavities disappeared without compression. The aim was a functional result—no sputum, no cavity, no pyrexia nor rapid pulse, and a good sedimentation-rate. The pretty picture of the lung compressed around the hilum was almost an anachronism and all cases should be selective—i.e., all cases should only have that degree of collapse compatible with a functional result.

Artificial pneumothorax cases frequently did badly because of bad mechanics. A cavity was seen and higher pressure prescribed, yet the mediastinum was already flopping and herniating. This herniation and flopping of mediastinum was a defect of the mediastinum, even as a femoral hernia was a defect of the femoral canal. It was seen with negative pressures and the treatment was twofold—phrenic evulsion or paraffin and gomenol. In all cases the mediastinum should be stiffened by giving 2 c.cm. of paraffin-gomenol; wait until the usual reaction was over and then in three days 5 c.cm. and in another few days 20 c.cm. It was not necessary to try to put the oil on the mediastinum; put it in the pleural cavity and it would stiffen up the mediastinum in a fortnight.

Keep an eye on the fluid and remove before it did damage. To assert that cases with fluid did as well as those without was inaccurate; the comparison

was between cases where fluid was allowed to remain and where fluid was removed. Many fluids would be found to have tubercle bacilli, and tuberculous empyemata were not as dangerous as was commonly supposed. A rapid method of irrigating the pleural cavity was essential, a vacuum being rapidly produced by a water pump, and Carrel-Dakin solution, acriflavine, weak methylene-blue, or paraffin-gomenol used for disinfecting. Each had its value but Carrel-Dakin must not be used in the presence of pneumopulmonary fistula.

On the continent there was a vogue for cauterising adhesions and much pretty work was done. It was assumed that on completion of an artificial pneumothorax recrudescence occurred around adhesion. Experience in this country did not confirm this assumption. Adhesions that interfered with functional results must be dealt with by severing, by phrenic evulsion, by a combination of both, or by thoracoplasty. Of the various thoracoscopes, the Gullbring instrument of the Uveright type was excellent. Cauterisation was tedious and not free from danger. The mere existence of adhesions was no justification for interference; but a cavity held out by adhesion three to six months after induction called for treatment. Phrenic evulsion should be the first line of attack and thereafter cauterisation necessary.

Phrenic evulsion as a sole procedure had only slight value. Unless artificial pneumothorax was performed for minimal disease—a procedure not to be recommended—phrenic evulsion should be performed to spread out refills and to control cavities. The operation could be performed through a small incision and did not disfigure. Some had given it up because of alleged dangers and surgeons did not like to have phrenic evulsion done before a possible thoracoplasty. But phrenic evulsion with artificial pneumothorax gave much better results than artificial pneumothorax alone.

Double artificial pneumothorax obviously would not give the results claimed in artificial pneumothorax for unilateral disease, but it had its victories.

Scalenectomy appeared to be futile; in 31 cases done at the Cheshire Joint Sanatorium in 1932 the results justified the abandoning of the operation. Apicolysis also had not been a success in their cases though better selection and newer technique might give better results. Thoracoplasty—complete or partial—was an operation to be grateful for; but its sphere of usefulness with the cases seen at the Cheshire Joint Sanatorium had not been large.

HUNTERIAN SOCIETY

A PUBLIC debate, organised by this society took place at Cutlers' Hall on Monday last on the motion
That Birth Control is Unnecessary in Modern Life

THE BISHOP OF ST. ALBANS said he was wholly opposed to birth prevention by artificial means. He had a very strong intuitive sense that the whole thing was repellant and, in the truest sense, unnatural. There was no argument in favour of regarding it as wrong; but in moral judgments the intuitive sense could not be ignored, especially when it was shared by a large number of people. Birth control was against the teaching of at least three great religions: Jewish, Christian, Mohammedan. It was unnatural because it set out to frustrate the biological ends of

Nature; moreover, the means were antisocial and antipatriotic. He was told that birth prevention was intended to meet the changed conditions of the world. What were those changed conditions? Were they slums? Then clear the slums. If poverty, why have poverty? It was a scandal to allow human beings to live under conditions which no breeder of thoroughbreds would tolerate for his animals. There was now much laxity in sex relationships, but to call this "changed conditions" was the worst form of defeatism; it was wrong to sit down under conditions which could be changed for the better. A good deal was said about hard cases in justification of birth prevention, and no one could have followed his profession for 39 years without meeting with hundreds of them. But what advice was to be given to a husband or a wife whose partner might be condemned to practical celibacy owing to the state of health of the marital mate? Would husband or wife be advised to go elsewhere for satisfaction? Ultimately, he was convinced, it would be imperative to go back to the only safe method, self-control. Why did a distinguished member of the medical profession move, in the House of Lords, for legislation restricting the sale and advertisement of contraceptives if, as was alleged, they were the gift of God and of science for the betterment of humanity? If there was danger the public should be told; but if there was no danger, why restrict the sale of contraceptives? Large families afforded the best kind of education; but if, on the other hand, one played with Nature, she had a nasty way of getting back on one in the end.

Dr. C. P. BLACKER asked whether those who opposed contraception expected people to practise abstinence? As a universal principle it was acknowledged that abstinence was impossible. Information had been obtained from 979 women as to their usual frequency of coitus: 2 per cent. indulged more than once a day, 7.6 per cent. once a day, 31.3 per cent. more than twice a week, and 40 per cent. once or twice a week. In the speaker's own practice, only six practised abstinence from coitus, out of several thousands. He believed that birth control was abused by many in this and other countries; yet it could at the same time be necessary. Civilisation had now passed from the phase of unplanned parenthood, and no one ought to try to induce women to have children if they did not want them.

Dr. HALLIDAY SUTHERLAND, commenting on statistics, said that women who consulted gynaecologists and psychiatrists were not normal, and this debate was concerned with the mass of the population. Obviously some form of control was necessary in life; it was the essential difference between man and the animals that the former could exert self-control. Was it implied that nobody could do without the sexual act, even for a limited period? Was it impossible for a married man to practise continence for 12 days in each month? After a child was born the mother should have no sexual intercourse for three months; was the husband to go elsewhere during that time? Apart from pregnancy, the act of coitus imparted to the woman valuable hormones. If the "safe period" was to be really safe it must be observed to the hour. The safest way of all was to maintain the practice of self-discipline. He would be a bold doctor who would ignore all this tampering with the natural course of Nature as an element in the too-high maternal death-rate.

Dr. E. R. T. CLARKSON insisted on the importance of thorough and conscientious study of this, or any

subject, before essaying to give advice and leading. Many gave advice on this matter who had no acquaintance with the cognate sciences, yet it was one of really vital importance to the nation, and all nations. Religious, ethical, and moral considerations were involved as well as sociological.

Sir WALTER LANGDON-BROWN said the Bishop had not discussed whether birth control was necessary, but rather whether it was right. We were again under the shadow of war, which might spread, and an expressed purpose of that war was to find room for the increasing millions of people of a country where birth control was ranked on the side of banditry in the penal code. The Bishop's chief point was that he disliked the methods of birth control, but Sir Walter would prefer to rely on reason than on intuition. If it was asked what ends it hoped to achieve by birth control, he would answer: life and health, so that a woman may space out her family according to her wishes and her means, so ensuring that the children will be brought up in good conditions. In early days it was looked upon as simply the ordinary course that a woman who gave birth to eight or nine children lost two or three early in life; but nowadays to lose a child was regarded as a calamity. Sir Walter gave instances of wives of labourers out of work with five or more children to keep, and urged that birth control for such was a pressing necessity. The object of marriage was mutual consolation and the enrichment of life; there was a great deal in it besides reproduction: out of instinct it was possible to build up something possessing high spiritual value. Because birth control was abused, however, it was the desire of the medical profession that it should not go uncontrolled. He agreed that abstinence was an impossible doctrine; celibacy was admittedly possible, but married celibacy was worst of all.

The Rev. Father MAGUIRE said that the Ten Commandments had raised woman to her present position, but the preaching and carrying out of birth control would degrade her lower than in pagan times.—Mr. WILLIAM IBBOTSON thought one should be no more ashamed to confess being hungry for love than being hungry for food. The former resulted in that priceless sovereignty the baby. Health was essential to perfect happiness, and health could be maintained only by adherence to primitive laws. We should not sacrifice our idealism on the altar of convenience.—Dr. KENNETH DICKSON said that most of the opponents of birth control based their position on religious rather than on scientific bases.—Dr. F. J. BENJAMIN also held that the ethical objections to birth control did not stand logical analysis. Birth control was certainly necessary among the poor; its use did not mean that the people concerned were licentious.

Other speakers followed, and the openers replied.

POST-GRADUATE COURSES IN BERLIN.—International courses are to be held in Berlin on the following subjects: internal medicine (Feb. 24th to March 4th), syphilis of the internal organs (March 5th to 7th), tuberculosis (March 16th to 21st), obstetrics and gynaecology (March 23rd to 28th), radiology (April 9th to 14th), abdominal surgery (April 20th to 25th), homeopathy (April 20th to May 16th). Courses in all the special departments including practical work will also be held. Particulars of all these courses may be had from the information bureau of the Kaiserin Friedrich-Haus, Robert-Koch-Platz 7, Berlin N.W.7.

REVIEWS AND NOTICES OF BOOKS

The Biology of the Individual

Edited by J. RAMSEY HUNT, M.D., THOMAS K. DAVIS, M.D., and ANGUS M. FRANTZ, M.D. Baltimore: The Williams and Wilkins Company. Pp. 323. 27s.

THIS is the fourteenth of the series of yearly publications by the Association for Research in Nervous and Mental Disease. It opens with a historical paper by Dr. Smith Ely Jelliffe, learned in range, followed by Dr. Charles B. Davenport's chapter on body-build and its inheritance, which is meagre but informative. The relation of morphological form to reflex action and behaviour is discussed on the basis of his own investigations on dogs by Dr. William T. James; a more useful paper is that of Mr. T. Wingate Todd on the progress of physical maturity and mental expansion in children. Prof. Arnold Gesell's contribution on the ontogenetic patterning of infant behaviour gives a very brief account of some of his brilliant work at the Clinic of Child Development at Yale. A lucid survey of the relation between constitution and internal medicine by Prof. Levellys F. Barker is followed by a detailed account of endocrine aspects of constitution by Dr. Walter Timine. Biochemical aspects are reviewed by Dr. Max Goldzieher. Prof. Eugen Kahn gives a critical survey of the formulation by Kretschmer and others of the constitutional features of personality types. One of these, the eidetic, is dealt with at more length by Dr. Heinrich Klüver.

Prof. Macfie Campbell's balanced statement of the relation between personality and psychosis introduces the more psychiatric part of the volume. Special studies made in this field are reported by Dr. Karl M. Bowman from the Boston Psychopathic Hospital, and by Dr. R. G. Hoskins and Dr. E. Morton Jellinek from the Worcester State Hospital. Prof. Allport's presentation of the relation between individuals and their human environment is appropriately followed by Dr. William Healy's temperate consideration of delinquency as an individual problem. An airy, loosely written paper by Dr. Paul Schilder on personality in the light of psycho-analysis, a note on handwriting and the Rorschach test in relation to personality by Dr. Oskar Diethelm, and a report of investigations into sexual development by Dr. George W. Henry conclude the book. Reports of the discussions that followed each paper when it was read are included, but only in a few instances is a list of references to the literature of the various topics appended.

An Introduction to General Therapeutics

By H. K. FRY, D.S.O., B.Sc., M.D. Adel., B.Sc., D.P.H. Oxon., Lecturer in Materia Medica and Therapeutics in the University of Adelaide. London: Cassell and Co., Ltd. 1935. Pp. 223. 6s.

UNDER this title, borne by a very small book obviously written for junior students, one might expect a simple presentation of the principles of therapeutics, illustrated by common examples. In the preface, however, the author says that he aims at a concise survey of modern methods of treatment, dealing with the principles underlying their use, and their possibilities and limitations in practice. The book is consequently disappointing; for it attempts too much in too little space. Such principles as appear in it are set forth too baldly, and without adequate

illustration. Long stretches of it are dry statements about the uses of drugs, and there is scarcely even room for mention of the evidence on which a statement is based. The field is not confined, of course, to drugs and chemical preparations, but ranges over endocrine treatment, immunology, dietetics, physiotherapy, psychotherapy, and climatology. The result is an agglomeration of facts, to be accepted as such on the author's authority; they may help to fill the storehouse of the inquisitive student's mind, but so set forth they do nothing towards stimulating his thought, or training his critical faculty. Teachers do not get the best out of their students in this way.

The Autonomic Nervous System

By JAMES C. WHITE, M.D., Assistant Professor and Tutor in Surgery, Harvard Medical School; Assistant Visiting Surgeon, Massachusetts General Hospital, Boston. London: Henry Kimpton. 1935. Pp. 386. 30s.

THIS is the most comprehensive review of the surgery of the autonomic system which has yet appeared in English. Since it has been written by a clinician of wide experience, who is endowed with a well-developed critical faculty, the book will be a great help to every practitioner who wants to know what surgery can achieve under certain stated circumstances. It is clear, for instance, that Dr. White's experience leads him to place little confidence in sympathectomy for asthma and epilepsy; and he does not hesitate to state, when referring to thromboangiitis obliterans, his own rather gloomy views in contrast with the more favourable opinions expressed by other surgeons.

Dr. White's work has been based upon the most recent discoveries of physiology, and has been controlled by the careful application of exact methods of clinical examination. It is therefore fitting that the first part of his book should be devoted to the anatomy and physiology of the autonomic system and to a description of the apparatus and methods employed for studying patients before and after operation. The reader will appreciate the care which has been taken to exclude unnecessary detail, and he will be struck by the extensive and ingenious use which is made of novocain to block autonomic nerve impulses. The second part is devoted to the consideration of the various conditions in which it is possible to modify the function of the affected organs by destruction of their nerve-supply, and the author has been careful to discriminate between the conditions which react favourably to operation and those for which sympathectomy has been performed with little justification and a correspondingly small degree of success. The importance in prognosis of the severity of various diseases under consideration has not, however, been sufficiently stressed, and the explanation offered for the unsatisfactory results in some cases of Raynaud's disease is unconvincing. The suggestion is that destruction of post-ganglionic fibres renders the denervated vessels supersensitive to circulating adrenaline; yet later on recurrent attacks of vasospasm are attributed to the excision of an inadequate number of ganglia.

The last section of the book deals with technique and gives a concise description of the various methods of surgical approach and of alcohol injection which are now employed for sympathetic denervation. The

accompanying drawings are all clear, with the exception of those illustrating the posterior approach to the cervico-thoracic ganglia, which seem to be upside down. The final chapter describes peripheral sympathectomy by crushing the mixed nerves in the lower extremity, a procedure, introduced by Dr. White and his colleague Dr. R. H. Smithwick, which constitutes a notable advance in the treatment of Buerger's disease. The value of the book is greatly enhanced by an extensive but well-selected bibliography.

Tumeurs de l'encéphale

By D. PAULIAN. Preface by Dr. CLOVIS VINCENT. Paris: Masson and Co. 1935. Pp. 216. Fr.30.

It is difficult to discover in what way the study of brain tumours is advanced by this monograph. It is a collection of notes relating to 46 oddly assorted cases of glioma, meningioma, neuroma, secondary carcinoma and tuberculoma, all of which, with one exception, appear to have come to necropsy. The notes in general are too limited to be of guidance either to clinician or pathologist. When the variety of the material is considered it is perhaps hardly surprising that there is little attempt to discuss in a general way the experience gained. There can be little doubt that more is to be learnt of cerebral tumours from the careful description and discussion of a small group of cases selected from a large quantity of material than from uncritical reports of a far larger number of consecutive cases. Considerable emphasis is laid upon the importance of ventriculography in the diagnosis of intracranial tumours, and a chapter is devoted to the description and discussion of this procedure. The author lays himself open to a suspicion of insufficient experience in stating (p. 139) that tumours of the hypophyseal region are rare, and (p. 36) that the type of secondary carcinoma most frequently encountered in the brain is that derived from chorion carcinoma. There are many inaccuracies in the spelling, references, and the names and nationalities of authors. The poor quality of the many illustrations is probably to some extent attributable to the printing.

Diseases of the Nervous System

Sixth edition. By S. E. JELLIFFE, M.D., Ph.D., formerly Professor of Psychiatry, Fordham University, New York; and W. A. WHITE, M.D., Superintendent of St. Elizabeth's Hospital, Washington. London: H. K. Lewis and Co., Ltd. 1935. Pp. 1175. 42s.

THIS edition is arranged on the same general lines as its predecessors. About two-thirds of the book is devoted to organic diseases of the nervous system and the remaining third to the neuroses and psychoses, in which epilepsy is included. The authors state that they have undertaken to include as far as possible all important contributions of sufficient weight which have been made since the last edition. The book suffers severely from an attempt to cover too much ground, and a resulting lack of proportion. Nearly half the section concerned with organic diseases is devoted to methods of examination, vegetative and visceral neurology, and the endocrinopathies. The inclusion in these sections of blood syndromes, achondroplasia, myxedema, cretinism, and Addison's disease occupies space which might have been used to better advantage, for a number

of important neurological topics are inadequately treated. Compression of the spinal cord including spinal tumour receives four pages, less than the space allotted to diseases of the suprarenal bodies. Intracranial aneurysm is only briefly mentioned, and the clinical picture of subarachnoid hæmorrhage is not described. Subacute combined degeneration is not clearly differentiated from a motley group of "combined scleroses." In a book of more than 1100 pages the radiographic diagnosis of intracranial tumour receives only six words. Treatment is not described in sufficient detail, except the treatment of neurosyphilis. It is mainly in the realm of recent developments in neurology that the shortcomings of the book are to be found. Much of the older material attains a high standard. The historical background is valuable; the references and footnotes are well chosen; the illustrations, except for the absence of radiograms, are excellent; and the printing and format leave nothing to be desired. Both the student and the practitioner of neurology, however, have a right to expect that a new edition of an important text-book shall be thoroughly up to date.

John Bellers

Quaker, Economist, and Social Reformer. By A. RUTH FRX. London: Cassell and Co., Ltd. 1935. Pp. 174. 6s.

THE advances in public health made by Chadwick, Southwood Smith, and Simon during the first sixty years of the last century were so remarkable that they obscured for some time what was achieved by earlier workers in the same field, the value of whose work is now becoming more fully appreciated. Sir George Newman has shown what we owe to Haygarth, White, and other clinicians in the eighteenth century, who by their writings and practice did much to further the progress of preventive medicine; and in this book Miss Fry introduces us to an earlier pioneer. John Bellers was not a medical man but a successful cloth merchant, and health reform was only one of his many public activities. His first scheme was to set up a number of industrial communities for the education and employment of the poor, and the pamphlet in which he set it out won the commendation of Robert Owen, who reprinted it in 1818, and of Karl Marx, who described the author as "a veritable phenomenon in the history of political economy."

But Bellers has a special claim to our attention now. He studied the Bills of Mortality, from which he computed that 100,000 persons died annually "of curable diseases for want of timely advice and suitable medicines"; and he thought that since three-quarters of the population were too poor to procure either the State should provide what was necessary. He recommended the building of hospitals, the appointment of sufficient doctors for the domiciliary care of the sick poor, the encouragement of research, and special steps to secure the wide distribution amongst the medical profession of available knowledge of health and disease. He thought that the State should send out doctors to the East and West Indies in search of remedies, and that all ships' surgeons should be encouraged by suitable rewards "to make what useful discoveries they can in every country they come to." He attached importance to the keeping of clinical records, and thought that an autopsy should be made in the case of every patient dying in hospital. He aimed at a high standard of medical education in this country, "which may

prevent many from travelling to foreign hospitals to learn, when they shall be capable of doing it better at home." While he considered health problems from the point of view of cure rather than prevention, he was modern in his demand that the State should assume responsibility for promoting medical research and for providing adequate treatment.

Altogether Bellers was an interesting man, and Miss Fry has done well to tell us what is known of his life and to give sufficient extracts from his writings to establish her claim that he was a notable pioneer in social reform.

Introduction à la chirurgie thoracique

By E. E. LAUWERS. Paris: Masson et Cie. 1935. Pp. 112. Fr.20.

THE object of this book is to provide a concise account of the present position of thoracic surgery suitable for the student or graduate without extensive previous knowledge of the subject. Artificial pneumothorax is advocated if one month's rest fails to bring down the temperature and is also considered essential if relapse occurs after one period of sanatorium treatment. Adhesions should not be divided during the first six months of pneumothorax treatment. Thick-walled cavities when dry require no treatment; when sputum is present they always require closure by surgical methods, artificial pneumothorax being useless either because collapse is prevented by massive adhesions or because the fibrous shell of the cavity resists pressure. To be readable a book of this kind can hardly avoid being dogmatic and the author must be excused when, in expressing a general truth, he overlooks numerous exceptions. The absence of any illustrations is regrettable.

Nouveau traité de médecine

Fascicule XX. Pathologie du Système Nerveux. Published under the direction of Profs. G. H. ROGER, F. VIDAL, and P. J. TEISSIER. Paris: Masson and Co. 1935. Pp. 984. Fr.130.

THIS volume, a member of a well-known and valued series, is devoted to the pathological anatomy of the brain stem, cranial nerves, meninges, and spinal cord, other parts of the nervous system having been dealt with in the two preceding volumes. Famous French neurologists are amongst the contributors: thus G. Guillaumin and Th. Alajouanine provide sections on the mesencephalon, pons, and medulla; J. Froment on the cranial nerves; while J. A. Sicard and J. Huguénau, A. Léri, J. Thiers, J. A. Lièvre, O. Crouzon, and Ch. Chatelin are responsible for other sections. The title of the work is somewhat misleading. It is not primarily a treatise on pathological histology; the contributors are rather less concerned with the actual morbid processes at work than with the effects produced upon the patient. This is a book essentially of syndromes, and the anatomy of the changes that are correlated with such syndromes is described with a profusion of illustrations that are as much clinical as anatomical. This is particularly true of the first half of the text which is concerned with the brain stem. This section in particular will appeal to the clinical neurologist who is engaged in the analysis of lesions in this situation.

For the pathologist the parts dealing with the meninges and spinal cord will prove more attractive, including, as they do, descriptions of conditions that are little known and little understood, such as hæmato-

myelia and the various degenerations of the spinal cord. The omission of any reference to recent work on the aetiology of pernicious anæmia or to the possible rôle of vitamin deficiency in relation to these spinal cord degenerations is, however, disappointing. The description (p. 411) of Tay-Sachs's disease as a degenerative condition of the ganglion cells of unknown origin ignores the widely accepted view that this disease is a metabolic disturbance closely allied to Niemann-Pick's disease, in which there is a storage of lipoids in the ganglion and glial cells of the central nervous system, as well as in other tissues. Defects of this order weigh lightly against the value of the work as a book of reference correlating anatomy with clinical neurology.

Handbook of Physiology

Thirty-fourth edition. By the late W. D. HALLIBURTON, M.D., F.R.C.P., F.R.S., formerly Professor of Physiology, University of London, King's College; and R. J. S. McDOWALL, M.B., D.Sc., F.R.C.P. Edin., Professor of Physiology, University of London, King's College. London: John Murray. 1935. Pp. 971. 18s.

THE general features of this book are unchanged in this edition which is not, however, simply a reprint of the previous one, for verbal alterations have been made throughout in the interests of clarity, a few figures have been changed, several paragraphs have been abbreviated to allow the insertion of new matter, and two or three sections have been rewritten. Although the pagination is the same as before, it may fairly be said that the book has been brought up to date. The preface to this volume is liable to mislead those unfamiliar with the recent development of work, since it is almost identical with that of the thirty-third edition, the same reference being made to new features and to the almost complete rewriting of the book in the "last three editions." The index is excellent, being much more exhaustive than is usually found in a volume of this size. The book will continue to appeal to those who require a short, readable, fairly complete but not too advanced account of the subject as a preliminary to the study of medicine.

Tuberculosis of the Lymphatic System

By RICHARD H. MILLER, M.D., F.A.C.S., Assistant Professor of Surgery, Harvard Medical School; Associate Surgeon, Massachusetts General Hospital. New York: The Macmillan Company; London: Macmillan and Co. Pp. 248. 17s.

Dr. Miller gives in this monograph a straightforward account of tuberculosis as it affects the lymphatic glands. In America, as in this country, tuberculosis in this site is becoming much less common; but this cannot be attributed to any great advance in treatment, which indeed has remained almost stationary during the last thirty years. The absence of real progress in therapeutics is revealed in most of the chapters of this book. The remarks on the unsatisfactory results of tuberculin and the uncertainty of cure by the operative removal of cervical glands are in accordance with the experience of most surgeons, but it is depressing to learn that in the author's experience the same uncertainty and unreliability applies to the use of X rays. More information might have been given in the chapter on abdominal tuberculosis, but in general the book impresses the reader with the sanity of its outlook.

THE LANCET

LONDON: SATURDAY, NOVEMBER 23, 1935

TEACHING OF MEDICAL PSYCHOLOGY

FOR a long time, to all intents and purposes, the field of psychological medicine has been divided into two. The need for institutional care seemed to separate sharply the insane from the sane, the psychotic from the neurotic; and administrative and traditional usage caused a parallel cleavage in medical work: the "asylum doctor" or alienist cared for the lunatic, while the general physician treated—or disdained to treat—the sufferers from "nerves." Some of the latter patients passed into the hands of the neurologist when diseases of the nervous system became a differentiated specialty. The doctors in each group saw little of the illnesses complementary to those they were familiar with; their views about the whole subject were correspondingly partial, and were all the more tenaciously held because they were the outcome of intense but narrow experience. This state of affairs has changed since the war in that the neurologist has had to cede much of his territory to the psychotherapist. But the general line of division is still commonly drawn between those who work in mental hospitals and those whose contact with mental disorder is in the consulting-room, the out-patient department, or the wards of the general hospital. Each group shows misunderstanding of the other's position, tends to belittle its competence in the subject as a whole, and would be reluctant to entrust to it the teaching of psychological medicine.

This last is an immediate issue; for the teaching of psychological medicine as a whole is becoming more and more plainly a necessary part of medical education. To split it under the two heads—insanity and the psychotherapy of neuroses—would be justifiable only if there were no teachers with knowledge of the whole field, or, on the other hand, if one believed that disturbances in psychic life are due to a different order of causes, call for different principles of treatment, and exemplify quite different laws of normal and morbid function according to whether or not they affect conduct to the point of social and suicidal risk. Neither of these conditions prevails; fully equipped teachers are available, and psychological medicine is essentially a single subject. The dichotomous view of mental illness is no longer held by those

who have had equal experience of both the "neuroses" and "psychoses." Psychiatry, as Prof. ADOLF MEYER has often pointed out,¹ is the "study and treatment of all abnormal conditions in which are involved man's behaviour and mentation"; hysteria and anxiety are as much included in it as melancholia and dementia præcox; and it will be taught best by those who have the widest experience. But although such teachers are available, there is still dispute about what they should teach. It is also questioned whether complete teaching should not be reserved for post-graduate students.

Dr. T. A. Ross's Morison lectures to the Royal College of Physicians of Edinburgh now published in full² form a helpful contribution to the problem. Dr. Ross is pre-eminent among that section of psychiatrists who are almost exclusively occupied in psychotherapy. He has had exceptional opportunities for judging the value of the psychological theories that may be applied to the treatment and understanding of neurotic illness, and though in these lectures he naturally refrains from dealing with the teaching of the forms and treatment of the grosser mental disorders, he puts forward cogently the very definite opinions he has come to hold about the teaching of medical psychology. With a plain vigour of statement corresponding to the outrightness of his views, he explains his reasons for having "thrown the Freudians and the semi-Freudians overboard as teachers of students," and his grounds of complaint against the doctors trained only in mental hospitals—to whom he restricts the term "psychiatrist." Those who would most dissent from his desire to sunder psychotherapy from other branches of psychological medicine would be the readiest to accept his very weighty plea for the teaching of the "great mass of psychological knowledge on which we are all agreed"; and, he adds, "by 'we all' I mean all intelligent people, not only psychologists." An elementary psychology, avoiding the dubieties and conjectures of the warring schools, is ready to hand and would be what in some schools it has already become—an invaluable part of medical training. Dr. Ross believes strongly that much of the treatment of the neuroses can and should be done by the general practitioner, and would have him learn about it from the physicians and surgeons in the wards, by way of history-taking and discussion of the patient's difficulties, rather than from a specialist. For a long time to come this can be only a pious hope. Dr. Ross perhaps under-estimates the special knowledge and technique which he has acquired and of which he offers in these lectures so simple a presentation. On such controversial matters, however, his experience and refreshing directness make his views very welcome at a time when the education of the medical student is being amplified on the psychological side, and when some would like to give it a very decided twist in this direction.

TREATMENT OF CANCER OF THE LARYNX

OWING to the absence of efferent lymphatics from the interior of the larynx, intrinsic cancer, which is nearly always epithelioma originating on the vocal cord, remains for a long time a strictly local process, and as such yields to treatment a higher proportion of cures than does visceral cancer elsewhere in the body. A further reason for this favourable result is the possibility of early diagnosis; for the lesion, being on the surface, is easily visible by means of a mirror, and produces the obvious symptom of hoarseness at a very early stage. It cannot, therefore, be too often repeated that any patient who is hoarse for more than a few weeks must have the larynx inspected by a competent observer. Provided that the growth is still amenable to complete excision by laryngo-fissure, 70-80 per cent. of cures can be obtained. Prof. CHEVALIER JACKSON, who with his son Prof. CHEVALIER L. JACKSON contributes to a symposium on the present-day treatment of malignant tumours,¹ claims 82 per cent. of cures in these cases, and describes a valuable modification of technique. This modification is especially suitable for cases in which the anterior commissure is involved, and brings within range of removal by laryngo-fissure a number of lesions which have been considered suitable only for laryngectomy. It consists in dividing the thyroid cartilage in the middle line without penetrating the internal perichondrium, preferably by means of an electrically driven circular saw. The perichondrium is then elevated as far back as necessary, first on the side least affected, and the growth is excised in one piece with a wide surrounding area of normal tissue. The extent and situation of the excision has to be guided by previous careful study of the appearances, since the interior of the larynx is not visible at this stage of the operation.

The selection of cases for surgery has been modified of late years by a great improvement in the results obtained with radium and X rays, and at the same time assessment of the malignancy of these tumours has been made more exact by Broders's classification into four types, of which the more malignant, though less successfully treated by surgery, are more amenable to radiation. The choice of operation depends on three factors—the site of the growth, the extent of the lesion, and the degree of malignancy. Laryngo-fissure is advisable in early intrinsic cancer of small extent, limited to the vocal cord; but extension to the anterior commissure is not a contra-indication, more especially when Jackson's modified operation is used. The same, however, cannot be said of extension posteriorly; when the growth has reached the posterior commissure leakage down the party wall between the pharynx and the larynx is rapid, and even laryngectomy yields poor results. Again, when the growth has extended upwards to involve the aryepiglottic folds or the base of the epiglottis, it is to be regarded as extrinsic and suitable only for laryngectomy.

In cases, then, which are strictly intrinsic, all four of Broders's types of malignancy are curable by laryngo-fissure, provided that the lesion is small. If it is large, and of type 3 or 4, a laryngectomy ought to be performed. When the aryepiglottic fold is involved, laryngectomy is justifiable in types 1 and 2, but Coutard's deep X ray therapy is better in types 3 and 4. Laryngectomy, therefore, should be done where an intrinsic cancer has extended so far posteriorly that there is a probability that laryngo-fissure will be inadequate, especially if of type 3 or 4, and in extrinsic disease of limited extent if of type 1 or 2; but if the extrinsic growth is extensive, or (if limited) of type 3 or 4, radiation is preferable to any operation. It will be noticed that JACKSON makes no mention of the method of treatment of intrinsic cancer by radium applied by fenestration of the thyroid cartilage, which has been successfully developed in this country by DOUGLAS HARMER, and which is perhaps more satisfactory than removal by laryngo-fissure when the lesion is rather extensive and especially when it is of type 3 or 4 of malignancy.

To recapitulate, in Prof. JACKSON's view laryngo-fissure is the treatment of choice for strictly intrinsic growths even if they are spreading to the anterior commissure, and for lesions which have involved the anterior wall of the arytenoid eminence if of types 1 and 2. Laryngectomy is indicated when the growth has reached the arytenoid if it is of type 3 or 4, and for limited extrinsic growths of types 1 and 2. For all extrinsic tumours of types 3 and 4, and for more extensive extrinsic tumours of any type, radiation is preferable to operation of any kind.

CHARLATANISM

QUACKERY is undoubtedly flourishing. In some European countries it is steadily increasing. Dr. WASSERBERG in an admirable essay¹ defines the charlatan or quack as "a person who engages in the treatment of the sick without possessing the requisite State authorisation for the purpose." In the United States the evil consequences of the wholesale freedom to treat the sick led to the passing of various laws against quackery, but whereas in Europe there are only two classes of "healer," the qualified doctor and the quack, in the United States a third class is recognised—namely, those with "limited licences" which comprises osteopaths, chiropractors, and numerous other healing cults. Dr. WASSERBERG dubs all these quacks, though, strictly speaking, they do not fall within the limits of his definition, being to some extent State-authorised healers.

Most countries prohibit quackery by law, but England and Germany are notable exceptions. In England, toleration of quackery is ancient and traditional; in Germany, it is comparatively recent, and the legalisation of quackery was actually supported in 1870 by VIRCHOW, LANGENBECK, and other men of liberal ideas who argued

¹ Amer. Jour. Surg., 1935, xxx., 3.

¹ League of Nations: Quarterly Bulletin of the Health Organisation, September, 1935, p. 555.

that "the State was not entitled to grant the prerogative of treatment to any one class or to limit the citizen's freedom to seek advice and help where he chose." As a political gesture, the monopoly of the medical profession to treat the sick was abolished in France and Russia during the revolutions of 1792 and 1922 respectively. In both cases however it was speedily restored, for it was found to safeguard the interests of the State rather than those merely of the medical profession. Latterly there has been a steady curtailment of the quack's legal rights both in England and Germany. It must be admitted that whether quackery is legally accepted or not in any given country does not seem to influence the number of quacks practising in that country. They flourish, for example, just as much in France, where quackery is illegal, as in England, where it is not. Moreover quacks, like doctors, are found in proportionately greater numbers in towns than in rural areas, whence it follows that quackery does not in any measure depend for its existence on a scarcity of doctors. An inquiry concerning 1301 quacks in Berlin brought to light some interesting facts. It was found that a considerable proportion of them had had no more than an elementary school education. Nearly three quarters of them were over 40 years old, an observation suggesting that they had probably tried some other career first. The men outnumbered the women in the ratio of about two to one. Many of these charlatans of both sexes were drawn from the auxiliary medical services; for which, says Dr. WASSERBERG, the medical profession is to be blamed, in too lightly entrusting such persons with responsible therapeutic tasks and so giving them undue confidence in their ability to treat the sick. Post-war unemployment must also have encouraged many to take up quackery as a means of livelihood, but although the desire to make money may be the strongest, it is not the only incentive to quackery as a career. Other strong motives are a desire to rise in the social scale, or a fanatical faith in some system of healing leading to the founding of new cults. Nevertheless the financial allurements must rank first. It is estimated that, in England alone, the money spent in fees to quacks would endow 40,000 hospital beds. Quackery is undoubtedly "big business," and the quack knows how to sell his wares. Minor licence holders in the United States are taught salesmanship in their training curriculum, and the power of the press is recognised and used to good purpose. There are 150 quack periodicals in Germany alone.

It might be presumed that the quack's clientele is largely derived from the ignorant and illiterate, but in fact the reverse is true. Most of those who seek advice from quacks belong to the educated classes. It may therefore be interesting to inquire into why such persons go to the quack rather than to the doctor. The reasons are many, but some are obviously more important than others. Facile princeps, perhaps, is lack of therapeutic satisfaction. The intelligent layman often will not, or cannot, reconcile himself to the fact that

he may be suffering from an incurable disease. No matter how many "orthodox" doctors he may have consulted, he will not accept the inevitable. Something, he feels, must be done about it, and so he turns to the quack. Whether or no he benefits thereby does not ultimately matter so long as the hope of recovery is kept alive. To such a patient anything is preferable to the cautious and reasonable pessimism of the honest doctor. Another important factor leading to disharmony between patient and doctor may well be the impersonal and objective method of approach which is bred of a modern scientific training. The "test-tube" doctor may lack that psychological perception which would teach him constantly to realise and remember that patients think of disease in terms of symptoms. To the patient, a "serious" disease is one which makes him feel ill or cramps his activities. Whereas the doctor is apt to dismiss lightly and treat casually minor ailments which may, subjectively speaking, be anything but trivial, the quack is unlikely to make this mistake. His very lack of pathological knowledge compels him to think and treat symptomatically, and the fact that he and his patient both talk the language of popular medicine makes for mutual sympathy. And what of the therapeutic successes of the charlatan? These are often more apparent than real. "Cures" are frequently claimed for diseases diagnosed only by the quack himself and, in reality, non-existent. Transient improvement in spontaneously remittent diseases is also hailed as cure. In some cases of self-curing disease the quack usurps the credit which rightly belongs to the healing power of nature, but it is among the functional disorders and the *malades imaginaires* that the quack is really at his best. Few such patients can remain completely impervious to his compelling and irresponsible optimism.

Finally, who is to blame for the continued existence of the charlatan? It would probably be just to reply, the doctor rather than the patient. We may accuse the sick layman of a taste for magic, of drawing false conclusions, and of a post-hoc-propter-hoc habit of mind; but the fact remains, when all is said, that if our therapeutics and methods of handling the patient were better, the *raison d'être* for the quack would disappear from civilisation and, with it, the quack himself.

SLEEP AND SLEEPLESSNESS

WE should understand insomnia better if we knew more about normal sleep. We may note the fall in systolic blood pressure, the slowing of pulse and respiration, the increase in oxygen intake, the reduction in carbon dioxide output, and the lowering of the basal metabolic rate and body temperature. These changes, as W. R. HESS has pointed out,¹ are in the vegetative functions most intimately connected with physical and psychic activity. But they are merely accompaniments of sleep; we can find no physiological change that is constant and essential. In general

¹ THE LANCET, 1932, ii., 1259.

terms the state may be described as a dissociation which affects the cortical centres chiefly and leaves the lower functions relatively unimpaired. That the lower centres in fact retain much power of action is shown by the "automatic" movements of the somnambulist, of the soldier sleeping on the march, and of the long-distance athlete. More rarely we read of useful mental activities: COLERIDGE is said to have created *Kubla Khan* in his sleep and MILTON tells of—

My celestial patroness, who deigns
Her nightly visitations unimplored,
And dictates to me slumbering; or inspires
Easy my unpremeditated verse.

Such examples make it clear that sleep does not, as is often supposed, imply deep unconsciousness. Rather does it consist in general relaxation of functions, the suspension of all effort—even the effort to go to sleep. As a rule the cessation of response to stimuli is the result of fatigue, and fatigue comes on more rapidly with inefficient working of the body; hence we are prepared to find that the more lowly organised the constitution the more sleep is needed. The short periods of sleep of intellectual men have often been remarked. Yet sleep and fatigue are not so intimately and reciprocally related as to simplify the problem how we sleep at all. For fatigue is not a necessary antecedent, and if excessive will indeed inhibit sleep. We sleep not so much because we are tired as in order to avoid becoming so; and the regular periodicity of sleep in a healthy person is a means of ensuring anabolic recuperation not only through physical rest but also by the avoidance of nervous stimuli with a katabolic effect. The attempt to eliminate all such stimuli is seen in the usual ceremony of going to bed, which includes the habitual disregarding of unimportant or familiar sounds—from street or farmyard, for instance. Reception is highly selective: the exhausted mother may sleep through the loudest noises but wake instantly at the faintest sound from her sick child; the doctor may be roused by the movement of wires preceding the ringing of his night bell. By a similar development of selectivity a patient will wake each time the clock strikes, and despite a good night's rest assert in all truth that he has heard every hour. Dr. H. M. NORTH, in an Australian discussion lately reported,² asks if the converse may not be true. Can a series of functional elements be rested whilst the organism as a whole is awake? Does the harassed business man sleep as the eager golfer watches his ball go prettily down the fairway? This is a question with direct bearings on the rationale of several forms of therapy, such as the prescription of a change of scene or occupation.

In assessing the effects of insomnia there seems to be no justification for the not uncommon fear of insanity; though sleeplessness is a common initial symptom in the psychoses. Naturally the discernible effects of experimental insomnia in man are meagre, while in animals that are kept awake they are apt to be confused with those of

muscular exhaustion.³ Nevertheless, lack of sleep undoubtedly plays an evil part in many an illness. Alternatively the rhythm may be deranged, and it is interesting to find a new remedy now suggested for the intractable day-and-night reversal often seen in encephalitis lethargica—namely, superior thoracic ganglionectomy, with which Dr. N. D. ROYLE reports success.⁴ In treatment of ordinary insomnia the first consideration is of course the relief of such obvious causes as pain, cough, dyspepsia, pruritus, disorders of micturition, as well as frankly recognised emotional disturbances—all of which are comprehended in the term "extrinsic insomnia." Direct treatment is similarly required in disturbances of the cerebral circulation, such as anaemia, vascular hypertension and hypotension, and cardiac decompensation. But often in practice the patient's needs have ultimately to be met by the skilful use of hypnotic drugs. They are needed not so much to give sleep as to re-establish rhythm. Where sedatives alone are required, the bromides still retain their popularity and the favourite combination with chloral is hardly surpassable. The numerous derivatives of barbitone are usually selected according to the individual experiences of the prescriber. The late Sir MAURICE CRAIG used to recommend a mixture of barbitone with sugar of milk; while the total amount was kept constant the proportion of the inert ingredient was nightly increased at the expense of the drug until none of the latter remained. CRICHTON-MILLER⁴ also recommends this method. NORTH² issues a warning against the use of morphia for an excitable patient except in association with hyoscine, whose depressing influence it corrects. That all hypnotics may be habit-forming drugs is emphasised by Dr. G. C. WILLCOCKS,⁵ who points out that this applies even to paraldehyde—a drug generally held to be too unpleasant to promote a habit. In alcoholics, he says, administration of paraldehyde probably replaces one form of dipsomania by another.

One can of course regard insomnia almost if not entirely from the psychological aspect. The difficulty of getting to sleep has been explained as due to the unconscious wish not to sleep, on the principle that any over-determined conscious emotion is the result of the opposite unconscious wish—here perhaps an unconscious fear of terrifying dreams. The field of investigation along these lines is almost unlimited.

On Thursday, Nov. 28th, at 5 P.M., at Charing Cross Hospital medical school, Prof. Edward Mellanby, F.R.S., secretary of the Medical Research Council, will deliver the biennial lecture on recent advances in science in their relation to practical medicine which was founded in memory of Thomas Henry Huxley, a former pupil of the school. Prof. Mellanby will speak on the rapid advance of science since the time of Huxley. Tickets for the lecture may be had from the dean of the school, Chandos-street, W.C.2.

ANNOTATIONS

A NEW SOURCE OF HORMONES

A PAPER communicated to the Biochemical Society on Nov. 15th by R. K. Callow, A. H. Laurie, and A. S. Parkes, affords an instance of an investigation leading to results in a widely separated branch of science. The work of the *Discovery Committee* on the whale fisheries has included an inquiry into the age of captured whales, one of the methods employed being an examination of the ovary of the female and a count of the old corpora lutea corresponding to the periodic ovulations. Since about half the females are pregnant, corpora lutea of pregnancy are common, and the availability of this material, collected together at the Natural History Museum in London, suggested an investigation of the hormone content, which was carried out at the National Institute for Medical Research. The investigation of the hormone content of yet another species is a familiar move in "academic" research, but in this instance the Gargantuan scale of the organs of the whale gives the result a practical importance. The clinical investigation and application of progestin, the hormone of the corpus luteum, has been seriously hampered by the high cost of reliable corpus luteum extracts.¹ No doubt an artificially prepared product will be on the market before long, but the available chemical methods are not easy, and it should facilitate the extraction of a natural concentrate if, instead of high-priced corpora lutea dissected from the sow's ovaries, and weighing about 1 g. apiece, the corpora lutea from whales, with the impressive weight of from 1 to 7 kg. each, are employed. The progestin content per gramme of the latter has actually been found to be comparable with that of fresh sow's corpora lutea. It is of particular interest to note that, whilst progestin had already, as might be expected, been found in corpora lutea removed fresh from the whale and immediately frozen,² the results now recorded were obtained with material collected under the ordinary conditions of whaling and preserved for many months in formalin. The availability of some thousands of these corpora lutea annually may lead to a striking change in the price of an important hormone.

SOME SOCIAL AND PSYCHOLOGICAL IMPLICATIONS OF ILLNESS

PHYSICIANS are reminded that they must treat patients not diseases, individuals not physiological systems. Most of those who would agree as to the necessity of this Hippocratic approach to medicine complain, however, of uncertainty in its application. The facts and procedure of which they can make use are so seldom set forth in text-books of medicine, or so vaguely alluded to, that it seems a matter of personal rather than collective experience, of common sense rather than science. This must always be in some measure true, as long as medicine remains an art. But there are now many studies which throw light on the problem of constitution and integration. It was in the field of mental disorder that these problems first received attention, since here they are most urgent. Psychiatrists are compelled by their subject matter to give thought to the connexions between different aspects of behaviour commonly distinguished as bodily and mental, and to see how

these influence each other. Modes of reaction, types of personality, the relation between mental type and physical habit, and the influence of past experiences on present responses are topics that the psychiatrist cannot evade. It is therefore not surprising that much, though by no means all, of the outcome of scientific study of these problems gained currency in psychiatry earlier than in other branches of medicine. But it is not, on that account, esoteric knowledge, shrouded in the neologisms of the psychopathologist, or relevant only to insanity. It is as much or more the product of investigations in physiology, genetics, and anthropology than of psychology and psychiatry. The fruits of these investigations may be found in a work entitled "The Biology of the Individual," reviewed elsewhere in this issue. Reminiscent in its title of the well-known Brugsch-Lewy collection of monographs, but less detailed and more coherent, it serves to indicate, as that series did, the growing importance of work on constitution and modes of reaction. If, because of its provenance, this book gives much space to matters that are of special interest to the psychiatrist and sociologist, it is none the less significant for internal medicine, in which the social and psychological implications of illness are not likely nowadays to be overlooked.

SUNNIER ELECTRIC LIGHT

THE thesis that illumination should no longer be regarded as serving a single purpose, that of providing light for vision, is developed in a publication that reaches us from America.¹ Dr. Luckiesh has collected a number of important observations, arising from his own experimental work and that of well-known American and European authorities, from which he concludes that under modern urban conditions, necessitating indoor life, the addition of short-wave (near ultra-violet) light has become essential for the maintenance of health. In other words, the majority of town-dwellers being deprived by their mode of life of the benefits attributed to unscreened sunlight, it becomes the task of the scientist and finally of the architect and the trade to adopt new standards in illumination. Dr. Luckiesh maintains that the simulation of sunlight should be adopted by progressive urban communities for indoor lighting, sunlight being now universally recognised as a powerful environmental factor. The physical factors involved are reviewed and also the therapeutic effects of irradiation with well-defined areas of the spectrum in the ultra-violet and infra-red regions. The observations of Hasselbach, Hausser, and Coblentz are summarised and the problems of transmitting media, reflection, and permanency of materials are discussed. Dr. Luckiesh points out that curative reactions should never be contemplated, but that the problem of "prevention" should be shouldered by the designer and architect under the inspiration of recognised medical and scientific knowledge. In conclusion definite proposals are made for sources of illumination responding to the supposed requirements.

This able study opens many questions which the medical profession would be well advised to watch closely. The importance to the vast army of town workers of the changes in illumination here

¹ Artificial Sunlight. By M. Luckiesh, D.Sc., Director Lighting Research Laboratory, Edison Lamp Works-National Lamp Works, General Electric Company, Cleveland, Ohio. London: The Technical Press. 1935. Pp. 254. 21s.

contemplated requires careful consideration, and the "emission" of the lamps to be used is not a question which should be left to the commercial interests concerned. Enough is already known of the possible ill-effects of over-exposure to unscreened sources of ultra-violet energy to deter us from using experimental methods in order to arrive at our conclusions. The experimental scientist is not on safe ground when he proposes to emulate midsummer sunlight. There will be no variations of intensities in the artificial source of illumination comparable to those of "rising" and "setting," no clouding and no seasonal variations, worst of all—no intermittance, or night. The more efficient the lamp the greater the danger to the public. Dr. Luckiesh remarks, and his words have a sinister quality, that in congested cities ground areas are being wasted to admit inadequate and uncertain daylight; that even at the present time, when adequate and controllable artificial light is economically possible, architecture and the indoor world are suffering from the daylight lighting habit. Even the recessing of buildings is deplored as uneconomical.

If the only remedy to the discomforts of life in over-built areas is to be found in such counsels of despair, it is time for public opinion to be aroused. Their application in Great Britain would be even more grievous than in more southerly regions; town-planners and even health authorities forget too easily that the geographical position of England should be carefully considered before American or continental suggestions are adopted. The fact that New York and Madrid are situated in the same latitude and that London is ten degrees further north should never be left out of account. The improvements and rebuilding of some parts of our northern towns have cast a permanent shadow on the surrounding inhabitants. There are some open places and playgrounds in our cities which have been converted into deep wells by "property improvement," and any further developments in this direction in the name of science should be resisted.

THE GORDON SYNDROME

IN the *Policlinico* of Oct. 14th L. Paterni and P. Maroncelli, of Rome, record the result of their studies of the peculiar encephalitic syndrome (rigidity, incoördination, ataxia, and paresis, accompanied by wasting) described by M. H. Gordon in 1932 as produced in rabbits by the intracerebral injection of suspensions of lymphatic glands from cases of Hodgkin's disease. As similar suspensions of glands from other conditions did not have this effect it was suggested by Gordon that intracerebral injection of the rabbit provided a biological test, of practical application, for lymphadenoma, which would be useful especially where the histological picture is atypical. As related in our issue of Oct. 19th (p. 895) confirmatory evidence of the diagnostic value of the test has since been published by van Rooyen and Ogilvie, by van der Hoeden and Hulst, by Davis, and by Bortolozzi. In 1933 however it was shown by Friedemann and Elkeles that suspensions of normal bone-marrow and occasionally of spleen and leucocytes can produce this same syndrome in the rabbit. Subsequently Mackenzie and van Rooyen confirmed this and showed that the action was not due to the proteolytic enzyme of Jochmann. There is an incubation period of one or more days before the encephalitic syndrome appears and histological examination of the central nervous system of the affected animals has revealed lesions indicative of meningo-encephalitis. Guinea-pigs develop the

same signs and lesions and van Rooyen has shown that ferrets are susceptible, but mice appear to be unaffected.

The Italian investigators tested lymphatic glands from seven patients by injecting suspensions of them intracerebrally into rabbits. The first patient had fairly typical Hodgkin's disease and a positive Gordon syndrome was produced in all of three rabbits. In the second patient Hodgkin's disease was associated with tubercle: glands removed during life, and others removed after death, produced the syndrome on intracerebral inoculation, but not on intravenous or intraperitoneal injection. The third case was one of tuberculosis of the glands of the neck, and the three rabbits injected were still healthy after three months. The fourth patient also had tuberculosis with bilateral lung involvement and positive sputum, and the two inoculated rabbits developed the syndrome after 16 and 18 days, dying a week later. In the fifth case—another instance of tuberculosis of the glands of the neck—one rabbit died after a few days from unknown cause, the other remained well for two months. The sixth patient had chronic leukemic lymphadenitis and the result was negative, while the seventh had chronic leukæmic myelosis (white cells 200,000) and the two rabbits which were injected both showed Gordon's syndrome. A suspension of the leucocytes from this last patient was now tested on two rabbits: one remained unaffected, the second developed meningo-encephalitis after ten days. A second case of myelocytic leukæmia being available, this last experiment was repeated with positive result in both of two rabbits. Paterni and Maroncelli found that suspensions of active material from the two Hodgkin patients gave negative results when injected into rabbits elsewhere than the brain. The histological lesions found in the central nervous system of the affected animals varied and their intensity was not in proportion to the severity of the symptoms. There was evidence, however, of myelitis as well as meningo-encephalitis so that the condition appears to be one of meningo-encephalo-myelitis with lymphocytic infiltration (especially perivascular), foci of necrosis, and retrogressive changes in the nerve-cells of the brain and spinal cord, the anterior horn cells being notably affected. The conclusions reached are briefly that Gordon's results with Hodgkin's disease are definitely confirmed; that a positive result is obtained more easily if the material is kept on ice for some time; that a positive result is obtainable also in other diseases of the haemopoietic system; that a positive result is obtainable not only with gland tissue, but also with spleen, liver, and nerve tissue; that the severity of the reaction bears no relation to whether the case of Hodgkin's disease is typical; that negative results may be obtained with blood, cerebro-spinal fluid, and skin, although the same case may give positive results with gland, spleen, and liver; that positive results may also be got in guinea-pigs, though less severe; and that in rabbits as little as 0.1 c.cm. of 20 per cent. suspension of lymph gland may be enough to cause the syndrome. Attempts at passage were all negative, and no protective properties were found in the blood of animals that recovered.

In a discussion of their results Paterni and Maroncelli emphasise the importance of the failure of passage, and consider that this is a strong argument against the infective nature of Hodgkin's disease. The syndrome is obtainable with tissues from normal persons and also in other diseases, so that Gordon's test for the diagnosis of Hodgkin's disease is not

specific. On the other hand, it opens up a biological problem as to the nature of the encephalitogenic agent existing in health and also in organs from cases of disease of the hæmopoietic system. Furthermore there seems no reason to doubt that the syndrome is of real practical utility for identifying glands from cases of lymphadenoma. In the hands of Gordon himself, who retains the rabbits for only a week after inoculation, glands tested at St. Bartholomew's Hospital from suspected cases of lymphadenoma over a period of three years gave the following results¹: glands from lymphadenoma cases, 35 tested, 30 positive; glands from conditions other than lymphadenoma, 67 tested, 67 negative.

FOR AND AGAINST DOCTORS

"If a hundred or a thousand people, all of the same age, of the same constitution and habits, were suddenly seized by the same illness; and one-half of them were to place themselves under the care of doctors, such as they are in our time, whilst the other half intrusted themselves to Nature and to their own discretion...."

THIS outline of a neatly controlled experiment, though of modern pattern and indicating a critical attitude to therapeutics which is generally regarded as peculiar to our own times, is actually taken from *Thoughts from the Letters in J. Lohse's translation of Petrarch*. The forecast of the result of such an experiment hazarded by Petrarch's medical friend is not flattering to our profession; but the compilers of the anthology "For and Against Doctors"² where it is to be found, with many other biting comments on our art, deem it not surprising that mediæval doctors were held in low esteem by the public; the qualified "leech" of the Middle Ages derived his knowledge almost entirely from Arabian commentaries on the books of Hippocrates and Galen and had little or no practical training. A large part of actual practice, however, was in the hands of unlearned men, generally in religious orders, who were probably like hospital orderlies or the village nurse, and acted independently. It is in the mediæval section of this anthology that we find most of its gems, though ancient Chinese records have yielded comments still apposite—for example: "The skilful doctor knows by observation, the mediocre doctor by interrogation, the ordinary doctor by palpation." The "modern" section is said to include only a few extracts from English literature of the nineteenth and twentieth centuries, culled almost at random, but, we may add, with fine discrimination. Here, as Dr. Hutchison and Dr. Wauchope point out, the praise is more generously bestowed than in earlier periods, but alas, even in an age of advancing technique and scientific discovery, it is mainly for kindness and moral support rather than for professional skill. If therefore we have dwelt here on the bitter rather than the sweet in this collection it is because much of the latter has an emotional flavour, being addressed to heart rather than to head. And also perhaps, because there is a malicious pleasure in letting others say what we are debarred from saying ourselves. For in the words of Miss Joyce Denys quoted at the end of this delightful anthology: "Of course everybody knows that Doctors never say anything unkind about each other, it is part of their Unwritten Law and a sore trial to nearly all of them."

ANATOMY AT ST. THOMAS'S

THE extensions and alterations of the anatomical rooms, which have been in progress in the medical school at St. Thomas's Hospital, are now complete, and a compact and well-equipped department was visited last week by fellow anatomists and others on Prof. A. B. Appleton's invitation. The new two-floored buildings occupy an area lying behind the old dissecting-room. The upper floor is given over to laboratories, including the professor's rooms and technicians' work-room; this position gives excellent lighting. The flooring here, and in the X ray room, is of Granwood, a composition in blocks looking very like wood, which seems to promise a long and serviceable life. Other rooms, on the lower level, comprise museums, filing offices and work-rooms, radiological and photographic rooms, and, of course, the dissecting-room. All these, with two lecture theatres, make a well-ordered and contained section of which the medical school may justifiably be proud.

Medical men whose first education in their profession dates back some forty years or so have memories of a dissecting-room and a cloak-room, and little beside this, in which they carried through their anatomical studies. It would probably cause them some astonishment to come within the circuit of a modern department of anatomy, especially if they have had occasion to read some recent remarks on the futility of anatomical knowledge, with the suggestion of the moribund senescence of the subject. There is no sign of such decay. On the contrary, there is enthusiastic research by numerous workers in ever-widening fields, and the dissecting-room is only one of the many laboratories which are necessities in every modern department. A visit to one such as this at St. Thomas's, with its modern methods both in work and teaching, should convince any honest mind that anatomy has advanced and widened more rapidly than some other subjects which come under the ægis of medicine.

A YEAR'S WORK ON ASTHMA

OSLER pointed out that the student of syphilis gets to know the whole of medicine. The Asthma Research Council is coming to much the same conclusion about the study of asthma. The latest report of progress¹ admits that the asthma problem has so many sides that rapid progress cannot be expected. The problem in fact still remains unsolved in its essentials, but at five centres work on a particular line of inquiry is going on with a view to laying bare one root of the baffling problem. At Guy's E. T. Conybeare and L. J. Witts have been estimating the degree of improvement which may be expected in asthmatics as the result of general medical care and advice without the use of any specific treatment. At the same time R. S. Bruce Pearson is attempting by physical methods to reproduce the conditions which the patient believes to have precipitated attacks. At Guy's all patients go through a probationary period of two months in which they perform the exercises recommended by the Council. Among asthmatic children C. H. Rogerson continues his study of the psychological factors lowering the threshold for stimuli which ordinarily produce an attack. The intelligence of these children is above the average, but many of them have to contend with a difficult environment, often indeed parental

¹ Asthma Research Council. Report of Progress for the Year ended Oct. 31st, 1935. Copies free from the secretary of the Council, c/o King's College, Strand, London, W.C.2.

over-protection. At St. Mary's over 150 cases of angioneurotic oedema have been investigated and nearly as many cases of migraine of an allergic character. Desensitisation having proved very laborious and exacting, the more intelligent patients are now being taught to inoculate themselves at home. Against the hay-fever season of 1936 a great store of antigen has been amassed: 28 lb. of pure grass pollen—equivalent, it is said, to 58×10^{16} grains of pollen. This yield has been rendered possible by building and equipping a pollenarium alongside six separate crops of grasses and grain grown on Lord Iveagh's estate at Pyrford. Heather pollen fever is regarded as not uncommon and provision is being made for that also. At King's College Hospital the physical side of treatment takes precedence. There it is accepted that the asthmatic is apt to breathe uneconomically even in the period between attacks. If three things can be secured—viz., (1) automatic diaphragmatic breathing, (2) a chest expansion of a certain degree, (3) ability to exhale continuously for at least thirty seconds—success in treatment is almost assured. In fact an attack can often be prevented from coming on by doing the exercises. At King's College work is biochemical. J. L. D'Silva has made it seem probable that in bronchial asthma the functions of the sympathetic nervous system are in some way depressed. In hay-fever patients it is found that the serum potassium is considerably higher than in normal people, this observation being the first evidence of a material difference capable of analysis between the chemical processes of asthmatic and normal persons. A broncho-dilator substance extracted from broom and resembling adrenaline is being prepared for clinical trial. At Leeds investigation is again on the physical side. Observations suggest that the over-expansion of the chest in asthma is not due to true emphysema; in fact the chief deformities observed in asthmatics often yield readily to treatment and breathing exercises are effective in correcting the observed deformities. Finally, at the Charterhouse Clinic G. S. Scott and Harry Coke are able to register the constitutional effects of X rays, applied in moderate doses to a large body area, by a serological precipitation test. Pure allergic asthma, they think, responds best to X ray treatment. The report mentions many other investigators and their work.

RADIUM PROTECTION BY BUILDING MATERIALS

THE use of radium in relatively large amounts for the beam treatment of cancer is extending, and the National Physical Laboratory is endeavouring to supply designers of radium departments with data on the measures which should be taken to secure for those who work near "bombs" a degree of protection up to the standards laid down in the International Recommendations for X Ray and Radium Protection. In a paper read last week by Mr. G. W. C. Kaye, D.Sc., in association with Mr. G. E. Bell, M.Sc., and Mr. W. Bink, M.Sc., before the British Institute of Radiology, the part which building materials can play in providing this protection was further considered. Their experiments were conducted under everyday conditions when scattered radiation is pronounced. The materials tested were full-scale walls of brick from 4 to 23 in. thick, of coke-breeze from 3 to 9 in. thick, and of concrete from 1 to 14 in. thick. Solid steel doors up to $4\frac{1}{2}$ in. thick, as well as various thicknesses of lead and aluminium, were also tested. Up to several grammes of radium were used as a source of radiation, and the

measurements were made by means of thick air-walled ionisation chambers, so as to simulate the conditions of deep-seated tissue. In the past it has been customary to regard the absorption of gamma rays by different materials as proportional to their densities, but Dr. Kaye and his colleagues have been able to show that while the relationship is sufficiently exact for the lighter elements, up to (say) barium, it requires correction when comparing light and heavy elements owing to photo-electric absorption in the latter. Protective values are generally quoted in terms of lead. When these are translated into terms of building materials by the aid of the density law, it now appears that the thicknesses deduced should be increased by as much as 40 per cent. for unshielded radium, and 60 per cent. for the radium beam from a typical present-day bomb.

THE IRRADIATED CELL

AT a time when intensity is the subject of discussion in every clinic where attempts are being made to establish a scientific basis for the technique of radiation a statement in the introduction to the green book on radium therapy just issued by the Medical Research Council¹ claims attention. Referring to the work of Mr. F. G. Spear, D.Sc., and his colleagues at the Strangeways Laboratory, it says:

"The reaction of the tissue which they have been using is not a simple function of the dose of energy released in it. They find in fact that to get a well-recognised effect there is an optimum intensity at which the release of energy may occur. That is to say the effect is observed with a minimum absorption of energy, provided that the energy is absorbed by the tissue at a particular rate."

The facts established by Dr. Spear are in general well known. The minimal threshold dose, latent period, diminution in cell division, and subsequent compensatory increase with abnormal mitotic figures are recognised biological responses to irradiation, and it is now possible with the help of the physicist to measure with much greater accuracy the dose actually received by the tissue which produces these effects. We are told that using the Sievert unit of dosage for gamma rays, working between 460 and 1660 units of dose, the existence of the compensatory increase depends on the intensity at which the dose was given. The intensity varied from 184 to 469 units, a ratio of one to 2.5, and the effect is seen with the lower intensity and longer time of exposure, but not with the higher intensity. To get this variation of intensity a similar variation in time is necessary, and it is again clear that intensity and time cannot be separated particularly with single doses. We thus return to the position, long since established by Regaud, that biological response is a function of at least two variables, dosage and time, on which intensity obviously depends. This is recognised by Dr. Spear who investigated this aspect of the response by fractionating the dose and found, for the tissue examined, that there was an optimum spacing for diminishing mitosis; it is of interest that in cultures derived from normal and malignant tissue, cultivated under similar conditions, the same dose of gamma rays causes a greater fall in cell division in the malignant than in the normal tissue growth. In-vivo experiments with chick embryos were used to show the relative importance of direct and indirect effects of irradiation. It was clearly demonstrable that the variation of mitosis following irradiation closely resembles that following

¹ The Medical Uses of Radium, see THE LANCET, Nov. 9th, 1935, p. 1083.

the exposure of tissue cultures to irradiation, and is a direct effect on the cell. The dose which has delayed lethal effect on the embryo is little over half that which affects the blood-vessels and destroys the circulation; but in the post-circulatory chick the compensatory effect, as given by the number of cells in mitosis counted over a period of four hours following irradiation, appears rapidly and gives a steep curve. This shows that the presence of a blood-supply has an important bearing on the recovery of the irradiated cell, but dosage high enough to injure the blood-cells or, at a still higher level, the endothelial cells of the vessel wall has not so far appeared to be compatible with the survival of the embryo; and although it is suggested that this effect is again a function of intensity it would appear to be a result of lethal dosage. Work by Miss Muriel Robertson, D.Sc., at the Lister Institute on *Bodo caudatus*, on which we commented recently,^{*} brings out two points: that there appears to be a "radium conditioning" in cultures exposed to gamma rays of radium at non-lethal intensity, and that when cultures are re-irradiated a full generation time may be used between re-irradiations without significant loss of total effect. Histological studies at the Bland-Sutton Institute suggest that vascular changes are superimposed on the direct effect with high intensities, but there is nothing to show that it is not the time factor rather than actual intensity which determines this.

If we attempt to relate these experimental findings to the clinical problems which confront us it is at once apparent that the question of intensity is not yet settled. The fact that fractionating the dose appeared to show that there was an optimum spacing, possibly different for different tissues, may be related to the "generation time" of the *bodo*, and the two findings together suggest that it may be possible to fractionate a dose, to obtain the full value of the time factor, without sacrificing the optimum intensity, should this prove to be higher than is compatible with continuous or prolonged daily irradiation.

VOLUNTARY HOSPITAL POLICY

WE learn from the Statistical Review issued by King Edward's Hospital Fund for London[†] that 2,139,000 sick and injured were tended by the London voluntary hospitals in 1934, 269,000 occupying beds and 1,870,000 being treated in the out-patient departments. These are record totals, the major part of the increase for each category being in 1934. A total expenditure of 3½ millions in 1930 rose to nearly 4 millions in 1934; the rise would have been greater had there not been some fall in prices during the period. Receipts clearly show the effects of the 1931 crisis. The 1930 total of £4,912,000 dropped during the next two years by nearly £600,000; a recovery of £100,000 in 1933, and a larger increase of £480,000 in 1934, brought the total up to nearly what it was at the beginning of the period. Voluntary gifts remained almost constant—a testimony to public appreciation of the work of the voluntary hospitals. Increased receipts from patients and public authorities for services rendered kept up the total ordinary income for maintenance. During 1934 the balance of income (including legacies) over expenditure for the whole of the 145 hospitals showed a narrow margin of £93,000; 91 hospitals had surpluses and 54 deficits. These figures for

1934 lead the economy committee of the Fund to draw two conclusions:—

(1) The work of the voluntary hospitals in London continues to grow not only in scale but also in quality as a result of the progress that has been made in curative medicine and surgery. The hospitals have thus been enabled to provide more and more effective treatment for a continually increasing number of the sick poor for whom they were originally founded and who remain their first care. The advances in therapeutic knowledge and skill have inevitably led to demands from other sections of the community that they should not be debarred from the benefits of the progress, and the voluntary hospitals, in adapting themselves to the changing conditions brought about by the ever-developing co-ordination of social life in this age, have met the necessities of the case by enlarging their field of service, which now includes not only the indigent sick and a large body of wage-earners who make substantial contributions either direct or through contributory schemes, but also persons of limited or moderate means who are admitted to pay-beds.

(2) In the aggregate the receipts, including both voluntary gifts and patients' payments, have kept pace with the increased maintenance expenditure. The voluntary gifts to maintenance show a substantial increase since the war, in addition to which large amounts have been received from this source to increase permanent endowments or to meet the heavy expenditure on schemes of extension and improvements or reconstruction at existing hospitals, as well as on buildings for new hospitals. This capital expenditure has been a marked feature of the finance of the voluntary hospitals in recent years, though since the crisis in 1931 some hospitals have had to postpone necessary expenditure for re-equipment, reconstruction, &c.

These figures may go far to dispel the doubts which are sometimes expressed regarding the present-day financial stability of the voluntary hospital system, but Mr. R. H. P. Orde last week expressed grave anxiety about the position. Mr. Orde is hon. secretary of the British Hospitals Association and he was speaking at the annual conference of the Incorporated Association of Hospital Officers. He recalled the departmental voluntary hospitals committee of 1921 which recommended Government grants towards maintenance and extension, the recompensing of hospitals in compensation cases, the remission of legacy and succession duties, and grants for training of nurses—all these things being measures of the barest justice. But because the voluntary hospitals were themselves without any machinery or organisation to compel consideration, this report came to naught, and the hospitals are still trusting to individual appeals to the heart. The strength of the voluntary system, he is satisfied, lies in its freedom from statutory control; its weakness is due to a lack of what might be called self-control. There are some who dread the acceptance of Government grants, but hospitals have taken and take money from where they can get it, and already they are supported as much from payments for services rendered as from charitable gifts. Let the voluntary hospitals in every area establish real and effective friendly contact with the public authorities; let them drop their wasteful rivalry, and let them look upon the voluntary hospital as part of a national scheme. The danger to the voluntary hospital system does not, in Mr. Orde's view, come from outside but is inherent in the system itself. Let it move while there is yet time.

THE Minister of Health has appointed a Central Housing Advisory Committee, under the new Housing Act, whose members will offer advice on questions submitted to them, and may make representations to the Minister on any subject of general concern in relation to housing. The names of the Committee are given on p. 1211.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXVIII.—PROGNOSIS OF ULCERATIVE COLITIS

DANGER TO LIFE

Hospital patients.—From a discussion on ulcerative colitis held at the Royal Society of Medicine in 1909 it emerged that no less than 141, or 50 per cent., of 288 cases collected from the records of seven London hospitals died in hospital. The ultimate mortality was presumably considerably greater. Bellingham Smith (1928) reported that 24 out of his 46 cases, or 52 per cent., had died, 13 under medical and 11 under surgical treatment. With this exception recent statistics have shown a smaller death-rate than that of the 1909 collection of cases. Thus J. R. B. Hern (1931) gave the mortality in Guy's Hospital of 50 cases between 1917 and 1926 as 28 per cent.; as an additional 12 per cent. died within a comparatively short time of their discharge the total mortality was 40 per cent. Hardy and Bulmer (1933) recorded 31 deaths among 95 patients in the General Hospital, Birmingham, between 1920 and 1932, a mortality of 33 per cent. The mortality was highest in the first year and thereafter diminished rapidly with every year of survival.

Private patients.—The statistics quoted above were taken from hospital patients. The mortality among patients seen in private practice, especially when they have had the advantage of institutional treatment, is very much less. Thus 7 out of 35 patients seen by E. Spriggs at Ruthin Castle, or 20 per cent., died there or in the two to twenty years which have elapsed since their admission. Of these, 2 received no treatment whilst at Ruthin, and 3 were hopeless on admission; the 2 former at least should be excluded, which would reduce the mortality to 12 per cent.

Forty patients with ulcerative colitis were admitted into New Lodge Clinic between 1921 and 1934. None died in the clinic, although in the large majority the disease was of a severe character, and only 3 have died since leaving it, in each case as a direct sequel of operation. The history of these fatal cases is as follows:—

1. The first was a woman of 56, who insisted on leaving the clinic at the end of a week, before there was time to institute any serious treatment. She was a case of average severity and should have done well with prolonged medical treatment. Unfortunately within a few days of leaving a colectomy was performed, in direct opposition to our advice, since a fatal issue from a one-stage operation in the acute phase of the illness was almost inevitable.

2. The second case was a woman with severe perianal suppurative and multiple fistulae in addition to ulcerative colitis. She was therefore transferred to a hospital for colostomy after being in the clinic thirty-seven days. The pelvic colon was accidentally perforated during the operation, and she died twenty-eight days later from general peritonitis.

3. The third fatal case was a man of 56 with severe colitis. Very little improvement occurred during the three weeks he was in the clinic. For family reasons he had to go to Ireland, where a month later an appendicostomy was performed, death occurring shortly afterwards.

If the patient who was in the clinic for only a week and died after colectomy shortly after leaving is excluded, the mortality is 5 per cent.; if she is included it is 7.5 per cent.

I believe that the mortality should not exceed

5 to 10 per cent. if patients receive adequate treatment for sufficient periods. As Hardy and Bulmer point out, there are few diseases in which a patient can reach such a state of emaciation and exhaustion and yet recover.

Table I. shows the contrast between the results in private and hospital patients—the Ruthin Castle and New Lodge Clinic statistics on the one hand, and those of Guy's Hospital (Hern) and the General Hospital, Birmingham (Hardy and Bulmer), on the other.

TABLE I

Total mortality-rate in private and hospital patients			
	Total.	Deaths.	Percentage.
New Lodge Clinic and Ruthin Castle ..	75	10	13.3
Guy's Hospital and General Hospital, Birmingham ..	144	51	35

PROSPECTS OF COMPLETE RECOVERY

I believe that a large majority of patients with ulcerative colitis, however severe, should recover eventually so completely that they are able to lead a life of normal activity. There is a very great tendency to recurrence, but as time goes on, especially if each recurrence is treated by complete rest in bed and by whatever other measures appear necessary from the earliest possible moment until the clinical evidence and sigmoidoscopic examination show that all traces of active disease have passed, the recurrences become milder and more infrequent until finally they cease.

Relapses tend to occur with acute infections, especially tonsillitis, food poisoning, dietetic indiscretions, exposure to cold and damp, and, much less frequently, fatigue from mental or physical overwork. If the first attack is thoroughly treated at its onset and treatment is continued for sufficiently long, relapses are unlikely to occur. I have only had an opportunity of seeing one case at the onset of the first attack.

The patient was a boy of sixteen whom I saw with Dr. W. H. Bradley at Downside in the early morning of the third day of his illness. He had a high temperature and diarrhoea, and large quantities of blood with pus and mucus were passed with each stool. Sigmoidoscopy showed the typical appearance of severe ulcerative colitis, and cultures made from the stools grew Flexner's dysentery bacillus. He was given 40 c.cm. of antidyenteric serum intravenously twelve hours later. The following evening his temperature fell to normal and it did not rise again. The diarrhoea ceased and by the thirteenth day did not even contain occult blood. There has been no recurrence in the eight years which have since elapsed.

When a patient first comes under treatment after he has already been ill for months or years, recovery is always very slow, and a year or more may elapse before he is able to return to activity. For the next few years he will remain very liable to relapse, but it is astonishing to find how complete the recovery may ultimately be in spite of the presence of severe organic complications, such as multiple strictures and polyposis. The appearance of the colon when examined after an opaque enema may show a complete disappearance of the normal outline, and yet the patient may have had no diarrhoea or other symptoms for years. In such cases the mucous membrane when examined with the sigmoidoscope

may be quite healthy, or it may show the presence of scars and occasionally of polypi, or a stricture extending to the lower end of the pelvic colon or into the rectum itself, when it may prevent the passage of an instrument more than a very short distance.

In Table II. I have adopted the classification used by Spriggs in his analysis of the Ruthin Castle cases, which include 13 of chronic ulceration after amoebic dysentery in addition to 35 of ulcerative colitis, and have added the New Lodge Clinic series of 40 cases of ulcerative colitis. I have had a report about every case but one within the last two months.

TABLE II

Cases of Ulcerative Colitis who received some form of treatment whilst at Ruthin Castle or in New Lodge Clinic from twenty to one year ago

	Ruthin Castle.	New Lodge Clinic.	Total.	Percentage.
Well and "carrying on"	34	32	66	77.6
No relapses	21	17	38	—
Relapses, but recovered from them	13	15	28	—
Not well, but "keeping better and about"	5	4	9	10.6
Ill	1	1	2	2.4
Dead	5	3	8	9.4
Total	45	40	85	

COMPLICATIONS

Table III. gives the frequency of the complications occurring among 693 cases treated at the Mayo Clinic (Bargen, 1929) and 40 cases at New Lodge Clinic. In many instances two or more of the complications occurred in the same individual.

TABLE III

Frequency of complications in 693 Mayo Clinic and 40 New Lodge Clinic cases

	Mayo Clinic.		New Lodge Clinic.	
	Total.	Per cent.	Total.	Per cent.
Polypsis	69	10	5	12.5
Strictures	59	8.5	5	12.5
Arthritis	30	4	1	2.5
Fistula-in-ano and perirectal abscess	26	4	5	12.5
Perforation	23	3	0	—
Cutaneous lesions	17	2.5	1	2.5
Cancer of the rectum or colon	15	2	0	—
Achlorhydric gastritis	—	—	3	9
Nephritis	8	1	1	2.5
Endocarditis	7	1	0	—
Ocular disease	5	1	1	2.5
Mesenteric thrombosis	3	0.5	0	—
Thrombo-phlebitis	—	—	1	2.5

Polypsis.—The first references to polyposis of the colon as a complication of ulcerative colitis appeared in *Guy's Hospital Reports* for January, 1925, when C. Ive described a case under my care at Guy's Hospital. Since that time polyposis has become recognised as a common sequel of partial or complete healing in very chronic cases, the actual incidence being about 10 per cent. The polyps form as healing occurs. Most are composed of mucous membrane, containing much inflammatory and granular tissue, but occasionally true adenomata develop. This has been proved by microscopical examination in several of my cases and also at the Mayo Clinic. The polypi are readily recognised with the sigmoidoscope, but they must be distinguished from the tags of mucous membrane which are occasionally left as islands in extensive areas of ulcera-

tion. Their extent can be recognised with the X rays, although much care is required in interpreting the radiograms. Polypi may give rise to hæmorrhage after recovery from the colitis, and they may also form foci of infection, which may be the starting-point of a recurrence.

Carcinoma may develop as a result of malignant degeneration of an adenomatous polyp occurring as a complication of ulcerative colitis, though the large majority of adenomata which become malignant are not secondary to any form of colitis. Fifteen such cases occurred in the Mayo Clinic series; many were in young individuals and the carcinoma was always of a high degree of malignancy. I have seen 3 cases, none of which is included in the New Lodge Clinic series. In 1 the growth developed three years after complete recovery from the ulcerative colitis. The second case was a woman of 50 who had been ill for several years; active ulcerative colitis, multiple polyposis, and a carcinoma of the rectum were all present together when I first saw her a fortnight before her death from exhaustion. In the third case a carcinoma developed in the cæcum in a man of 42, who had had symptoms for ten years; the ulcerative colitis was still active but showed signs of healing; two small polypi were present in the rectum. Death followed an exploratory laparotomy in which minute secondary deposits were found scattered over the whole of the parietal and visceral peritoneum.

Stricture.—The first record of the association of stricture as a complication of ulcerative colitis appeared in *Guy's Hospital Reports* for 1925, when Ive and Venables each described a case which had been under my care at Guy's Hospital and New Lodge Clinic respectively. Strictures develop in the course of healing of very chronic cases, generally without any change in the symptoms. As the rectum and pelvic colon are frequently involved, the condition can often be recognised with the sigmoidoscope. Its extent can only be ascertained with the X rays after a barium enema, which often reveals two or even three separate strictures. It is, however, very difficult to distinguish between an organic fibrous stricture and one resulting from spasm by either method, as a spasm may remain unaltered for weeks. An operation is indicated only if X ray examination after an opaque meal shows that there is stasis above the stricture in spite of the presence of diarrhoea. I have had three such cases, in each of which complete recovery followed a short-circuiting operation, without which death would almost certainly have occurred.

Perirectal abscess and fistula-in-ano.—Perirectal abscess is a serious complication. It may develop as a result of infection of one or more anal crypts from the purulent rectal discharge, or one or several fistulae may develop as long tracts burrowing high up the rectum from beneath the anal sphincter. This complication may occur during the active stages of the disease, but I have seen three cases in which it only became manifest after apparently complete recovery, giving rise on each occasion to a recurrence of the colitis of more or less severity. Painful anusitis with secondary spasm of the anal sphincter is a still more common complication—the result of long-continued diarrhoea, sometimes aggravated by carelessness in the administration of colonic douches.

Perforation.—Perforation of an ulcer occurred in 3 per cent. of the Mayo Clinic cases, but in only 1 of about 100 cases I have seen. It was, however, the

cause of death in 6 out of 38 fatal cases occurring among 55 cases at Guy's Hospital between 1888 and 1907.

Cutaneous complications.—Numerous cutaneous complications were observed in the Mayo Clinic series. The most important is the development of deep irregular sloughing ulcers. This complication occurred together with suppurative conjunctivitis, scleritis, and iritis in one New Lodge Clinic case; here both the cutaneous and ocular symptoms appeared to be the result of vitamin deficiency in an anæmic patient, suffering from a severe infection, who had been kept for a long period on a very inadequate diet. Pellagra may also occur under similar conditions.

Ocular complications.—Burrill Crohn (1925) has described the occurrence of conjunctival and corneal inflammation as a result of vitamin deficiency in patients with ulcerative colitis, who had for long periods been kept on too strict a diet. The condition is similar to the xerophthalmia observed in Central Europe during the war and in famines in India as a result of deficiency in fat-soluble vitamin A. Local treatment has no effect, but rapid recovery follows, as in the case complicated by sloughing cutaneous ulcers mentioned above, when the patient is given a satisfactory diet.

Arthritis.—Multiple arthritis, very similar to that occurring in acute rheumatism, is a well-recognised

complication of bacillary dysentery and it occurred in 4 per cent. of the Mayo Clinic cases of ulcerative colitis. I have only seen it once in about 100 cases of ulcerative colitis. It was accompanied by high fever and affected numerous joints for short periods, exactly as in acute rheumatism, though it did not respond to treatment with salicylates. The attack lasted about three weeks, leaving the joints without deformity and with perfect freedom of movement.

Circulatory and renal complications.—Suppurative pyelophlebitis might be expected to be a common complication, but it has only been seen once in 1200 cases at the Mayo Clinic, and I know of no such case recorded in England. Mesenteric thrombosis occurred as a rare complication in the Mayo Clinic series, and I have seen one case with recurrent thrombo-phlebitis in the veins of the legs. Infective endocarditis is another rare complication.

Nephritis occurred in 1 per cent. of the Mayo Clinic cases. A woman of 35, who was admitted to New Lodge Clinic with very severe ulcerative colitis, was found to have severe *B. coli* pyelo-nephritis; at the end of three months, by which time she had completely recovered from the colitis, the urine was perfectly normal and was sterile on cultivation; she had been given 360 grains of alkali a day.

ARTHUR F. HURST, D.M., F.R.C.P.,
Senior Physician to Guy's Hospital.

SPECIAL ARTICLES

BRITISH MEDICAL ASSOCIATION

MEETING IN MELBOURNE

SECTION OF DISEASES OF CHILDREN

Dr. ROBERT HUTCHISON presided at this section when Dr. A. JEFFREYS WOOD and Dr. IAN WOOD (Melbourne) contributed jointly a paper on

Pink Disease

An excellent description of pink disease by Selter of Solingen, published in 1903, attracted little attention until Swift of Adelaide restated the syndrome in 1914. In a series of 200 cases in Australia, all were under 4 years of age. The pathology was indefinite, the nervous system showing variable and inconstant minor changes, probably no more extensive than was to be expected from a terminal infection. At present they preferred to maintain an open mind as to the site of attack of the noxious influence, and would rather visualise it as a toxin diffusely distributed throughout the body. The causation of pink disease was unknown, but several theories had been brought forward. Drs. Wood thought that the avitaminosis theory was inconclusive, on account of the relative frequency of the disease in Australia. This favoured rather the light-hypersensitivity theory of Braithwaite; but against this theory was the fact that cases of pink disease did better if nursed in the open air, and moreover an analysis of cases failed to show that the greatest number occurred at the season when the hours of sunshine are at a maximum. The infection theory was the most attractive. Although attempts to demonstrate the presence of organisms had been vain there was much indirect evidence in favour of a virus infection. Many cases started with a febrile attack, and often the disease seemed to have been contracted after contact with a

victim. The fact that adults and children under one year were seldom affected could be explained if the virus was widely spread throughout the community in a mildly pathogenic state, giving the parent and young child an immunity. On rare occasions the organism would assume a pathogenic rôle in a highly susceptible individual, usually a child aged between 8 and 18 months. This would explain the infrequency of transmission by direct contact, and also the occurrence of sporadic cases in isolated parts of Australia. Dr. A. J. Wood outlined the symptomatology of pink disease, emphasising its prolonged and natural course. Up to the present no successful specific cure had been found. Symptomatic treatment, although it could not greatly alter the course of the disease, would lessen the discomfort of the sufferers, and alleviate the mental and physical stress of the parents. His own practice was to order light clothing with cotton, or preferably silk, next to the skin, and nursing in a perambulator or cot in the open air, with graded sun baths during the daytime and a tepid bath night and morning to the whole body, followed by gently rubbing with methylated spirits and application of dusting powder. If the fingers and toes showed irritation, equal parts of methylated spirits and tr. iodine applied as a paint would prevent onychia and at the same time lessen oral reinfection. Stomatitis was prevented by allowing the child to suck a wool and gauze swab soaked in 1 in 4 hydrogen peroxide. Younger children did well on a diet of unboiled cow's milk, those under two showing a great dislike for solid foods. Some older children seemed to enjoy raw vegetables and fruits. A mixture of bromides and chloral hydrate might be useful in insomnia. The mortality in treated cases would be less than 5 per cent. at home, but 30 per cent. in hospitals. This was due partly to the more severe cases admitted, but mainly to the risks of cross-infection, the patient succumbing to bronchopneumonia, gastro-enteritis, or cystitis. Drs. Wood

emphasised the importance of nursing cases of pink disease in healthy surroundings and out of hospitals.

The PRESIDENT said that Australia had the credit of being the country in which pink disease was first definitely established as an entity. He thought the disease was less common in England, only about 30 cases being admitted to Great Ormond-street in the last five years. There had, however, been local outbreaks in certain districts, notably in the neighbourhood of Birmingham. He was completely puzzled as to the cause of pink disease. There was very little evidence in favour of vitamin deficiency, and the infection theory was still very inconclusive. He drew attention to the resemblance between pellagra and pink disease, and thought that they might have a common cause. Atropine had been highly praised by some continental writers, but he thought it of no great value.

Dr. EDGAR STEPHEN (Sydney) gave a bad prognosis in the presence of much insomnia or excessive sweating. An additional diagnostic factor was a glassy appearance of the bones (resembling scurvy) and pencilling of the centres of ossification. Intranasal feeding might become necessary. He had seen one case of foot-drop as a sequela, and one of pellagra which he thought was due to deficiency following an initial attack of pink disease with starvation. In his experience the main cause of death was sudden heart failure.

Dr. S. F. McDONALD (Brisbane) had seen pink disease in children of many different nationalities, but never in aborigines or half-castes. The disease had many points in common with poliomyelitis, but the infection was probably in the sympathetic system. He described a case of a man aged 31 who appeared to have contracted pink disease.

Dr. ROBERT SOUTHEY (Melbourne) also mentioned the close analogy between pink disease and poliomyelitis. He knew of one family in which three children had had pink disease; one child subsequently developing poliomyelitis and finally herpes zoster. He had treated cases of pink disease with pooled human serum, and considered that some had benefited. Although the blood calcium was normal, large doses of calcium improved the sweating and skin irritability. Treating pink disease usually meant treating the wrecked nervous systems of the parents.

Dr. F. N. LE MESSURIER (Adelaide) had seen three cases of pink disease following antral infection, and suggested upper respiratory infection as a focus.

Dr. A. P. DERHAM (Melbourne) had seen several cases with reddening of the tympanic membrane. Paracentesis did not relieve the symptoms and no pus was obtained.

Dr. F. KINGSLEY NORRIS (Melbourne) said that the parents should be told of the chronicity of the disease and reassured as to prognosis. One case of double foot-drop with peripheral neuritis had made complete recovery. Some colloidal silver preparation as an eye-drop was helpful in preventing secondary oral and nasal infection, and mercurochrome was less painful than iodine on the fingers.

Mr. P. L. HIPSLEY (Sydney) read a paper on

Intussusception

He reviewed 486 cases of intussusception occurring in one hospital over 14 years, treated by ten different surgeons. The surgeons who operated in all cases had a combined mortality of 14 per cent., while those using a preliminary injection of saline per rectum had a mortality of 9.8 per cent. In his own series of 210 cases the mortality was 6.6 per cent. In a series

of 159 cases treated since 1918, 64 were reduced without operation, 32 were found reduced at operation, and 63 were unreduced. Injection had therefore reduced 60 per cent. The average duration of unreduced cases was 31 hours, as compared with 16 hours in those not requiring operation.

Many factors were concerned in intussusception. Anatomical features were: the disproportion between the diameters of the ileum and the caecum, particularly at the age at which intussusceptions occur; the greater mobility of the ileocaecal regions in infancy; the failure of rotation of the mid-gut loop, that is, the stage of fixation of the mesentery, which was commoner in males; the increased number of Peyer's patches in the lower ileum. A physiological factor was the possibility of irregular peristalsis in the ileum due to its double nerve-supply—both sympathetic and parasympathetic. Several cases had begun immediately after a fall, an occurrence which might set up irregular peristalsis. Rare pathological causes might be enteritis, dietetic errors, and neoplasms. Heredity probably played a more important part than was generally realised.

Difficulties in diagnosis were presented when intussusception occurred in enteritis and Henoch's purpura; and sometimes the surgeon might be misled by the absence of blood in the stools. This could happen when the invaginated bowel acted as a plug in the ileocaecal sphincter. The projection of bowel from the anus was sometimes mistaken for a rectal prolapse. The absence of abdominal distension in the early stages made palpation easier and helped the surgeon to diagnose reduction after rectal injection.

Mr. Hipsley gave a detailed description of the hydrostatic pressure treatment used by him. Under general anaesthetic, saline was run into the rectum from a glass container, 3 ft. 6 in. above table level, for from 3 to 4 minutes—the buttocks being pinched together to prevent fluid escape. The catheter was disconnected and the saline returned to a bed-pan. A second and then a third injection were given, the whole process taking about 10 minutes. The first return usually contained blood, the second was clearer and might contain some specks of faecal material, and the third showed more faeces and perhaps flatus—both facts indicating a probable reduction. The actual diagnosis of reduction depended on the distension of the abdomen by the saline passing into the small intestine—the circumference at the umbilicus increasing $1\frac{1}{2}$ to 2 in. Sometimes saline exuded from the mouth. If reduction occurred, but no saline passed, it was impossible to distinguish between thickened mucosa and unreduced intussusception. A small grid-iron incision was then made to verify the fact of reduction. If no operation was done, a teaspoonful of charcoal was put into the stomach by a catheter. Most of this should be recoverable five hours later by an enema. Disadvantages of the method were the possibility of (1) rupturing the intestine—this had occurred only once in 300 injections, where a small intestinal ulcer had perforated, manual pressure having been used on the abdomen—and (2) getting a false impression of reduction. In Mr. Hipsley's 64 unoperated cases this had never occurred. The advantages were that 40 per cent. of cases could be cured without operation, and nearly all cases were at least partially reduced—a grid-iron incision enabling the surgeon to complete the process. In conclusion, Mr. Hipsley recommended operation when there was no definite proof of reduction, when a partially reduced intussusception

could be felt, in recurrent cases, in a long-standing case when it was impossible to feel the tumour either before or after treatment, and in subacute and chronic cases in older children.

Dr. W. VICKERS (Sydney) said that the low mortality indicated that Mr. Hipsley's technique was good, but a less experienced surgeon might have some difficulty in being sure reduction was complete. The increased duration of anaesthesia was justified.

Dr. H. C. COLVILLE (Melbourne) considered inflamed Peyer's patches could cause spasm and initiate an intussusception, and the breast milk of late lactation might contain some irritant to lymphoid tissue.

Dr. R. DOWNES (Melbourne) had found that if a bowel resection was necessary, much less shock resulted if this was done extra-abdominally—the abdomen being temporarily closed with through-and-through silk-worm-gut sutures.

Mr. F. C. PYBUS (Newcastle) was impressed by the method and intended to try it. He thought that an oedematous patch in the bowel might initiate an intussusception, and he knew of a case where a woman suffering from angioneurotic oedema had two children who developed an intussusception.

Mr. HIPSLEY, in reply, said that the main disadvantage of extra-abdominal manipulation of an intussusception was the difficulty in telling when reduction was complete. The saline in the bowel did not tend to cause breakdown of the wound, because the partial reduction usually enabled a grid-iron incision to be used.

SECTION OF RADIOLOGY AND RADIOTHERAPEUTICS

Dr. R. A. GARDNER (Cairo) presided at a meeting of this section when Dr. J. G. EDWARDS (Sydney) opened a discussion on

Radiographic Diagnosis in Diseases of the Lungs

Nowadays, he said, no chest investigation could be considered complete without a radiographic examination carried out by a specially trained medical expert; the physician who attempted to interpret his own films would not be getting full value from the method. Physician and radiologist should make their individual examinations and then meet to correlate their findings. Fluoroscopic examination should be reduced to a minimum, being only of value in demonstrating diaphragm movements, in localising abscess or hydatid, and in the control of lipiodol instillations. He personally was in favour of the use of stereoscopic postero-anterior films for routine work, taken at 7 feet distance using 300 m.a. at 70 kv. with an exposure of about 1/30 second. Dr. Edwards said he would confine his remarks to a few conditions.

Apical Scars.—These, he said, were dense shadows at the extreme apices, common in working men, and looked upon as healed tuberculous lesions. They never appeared to break down, and if the person should develop tuberculosis it never seemed to be associated with the scarred area.

Effusions.—Atypical effusions might cause difficulty in interpretation. Interlobar effusions followed the interlobe and might assume various shapes. Some were triangular in outline and lateral films were then of value. Mesial effusions were rare, and when they occurred were usually associated with an oesophageal lesion.

Bronchiectasis.—This condition could usually be demonstrated in stereoscopic films, although it

might be overlooked if situated behind the heart or deep in the costophrenic sulci. Lipiodol instillation should only occasionally be called for and then the supraglottic route should be chosen. The amount of lipiodol should be as small as possible, otherwise a portion of lung might be "drowned."

Fibrin Bodies.—These were rounded shadows on one side of a chest which had been the site of a hydropneumothorax. On coagulation of fluid ball-like structures of varying sizes were formed which gradually disappeared after the lung had become fully expanded.

Fungus infections were rare. The only ones seen by Dr. Edwards were due to yeast or to actinomycotic infections. The former had showed a bilateral fuzziness with scattered areas of broncho-pneumonic consolidation; diagnosis was not made before death. In actinomycosis the lesion was at first localised to one lobe, later spreading in all directions. In many cases a "vesicular" appearance was typical.

Silicosis.—In conjunction with his brother Dr. Edwards had carried out extensive investigations into silicosis for the N.S.W. Government; they had found changes occurring in the lungs of rock-choppers, coal-miners, cement workers, asbestos workers, and tool grinders, the inhaled dust being dangerous in proportion to its silica content. Most authorities agreed that silicates produced no nodular fibrosis, but one silicate (that of aluminium and potassium) known as sericite had been put forward as a cause. The general opinion, however, was that it could not produce these changes by itself but that when present it hastened the action of silica in producing fibrosis. Hawkesbury (N.S.W.) sandstone contained free silica (80 per cent.), metalliferous ores (20 per cent. to 60 per cent.), and coal (2 per cent.). Coal-miners, however, frequently cut through seams of rock, and moreover sandstone dusting was used in some mines to carry down the fine coal dust which was liable to cause explosions. In this way the analyses of dusts as supplied might be misleading. Individual susceptibility might also play a part in silicosis; some men after 40 or 50 years of sandstone mining were unaffected, while others showed changes after 6 or 8 years. With a high silica content in the dust the onset of the disease was more rapid, and in lungs with damaged lymphatic circulation, whether due to tuberculosis or chronic bronchitis, the condition developed more rapidly. From other parts of the world cases of silicosis were reported after only a few years' work; this might be due to the greater prevalence of catarrhal conditions with consequent damaged lymphatic circulation and to less healthy conditions of employment abroad. The silica nodule was similar to the tuberculous nodule but never went on to caseation. The nodular fibrosis of silicosis was bilateral and spread from the hilum on each side, being somewhat more advanced on the right side. Once established the condition continued to advance even if the man was removed from his dusty occupation. The extent of the condition as shown in the film could not be taken as a guide to the worker's disability. Early stages of fibrosis might be associated with grave disability, while men with a most advanced fibrosis might show no disability.

Dr. J. O'SULLIVAN (Melbourne) stressed the importance of consultations between the physician and the radiologist. With regard to technique there were two schools of thought in Melbourne—one favouring the fixed or moving grid, the other discarding any diaphragm. He himself now used a fixed grid (Lysholm) with hard rays. Stephani (Switzerland)

also used this grid with voltages up to 150 kv. For lipiodol injections he used the method of instillation through a catheter after anaesthetising the pharynx, while controlling the injection by observation on the fluorescent screen so that the oil could be directed to the required area. He quoted a case in which a small ulcer was observed on the screen but could not be identified in the films. This small ulcer proved to be an early carcinoma. Dr. O'Sullivan then showed a series of slides made from X ray films to illustrate his remarks.

Dr. BURNETT CLARKE (Brisbane) did not favour fluoroscopic examination of lungs. Some physicians who brought their patients for examination seemed to forget that at least ten minutes in a dark-room was required for accommodation of vision before screening. A full clinical examination should be made before a patient was referred for X ray examination.

Dr. A. J. COLLINS (Sydney) said that in pulmonary tuberculosis it was difficult to decide when the lesion was healed. He quoted the case of a woman who after spontaneous pneumothorax had no demonstrable lesion but three years later had a small calcified area which had remained unchanged. This patient had since had several children without recrudescence. Another patient showed no demonstrable lesion one year after a spontaneous pneumothorax but four years later had developed calcification at the apex of one lung and tubercle bacilli in the sputum. A year later further calcification had taken place.

Dr. F. GWYNNE (Auckland, N.Z.) said that in New Zealand silica and sericite occurred in varying proportions in dust from mines. One district had a high silica content but a low incidence in silicosis, and at present the reason for this was obscure.

Dr. C. BADHAM (Sydney) said that the pathology of dust diseases was at present on a poor footing. He had been conducting animal experiments to reproduce working conditions, and although his guinea-pigs showed gross macroscopic lesions following the inhalation of quartz dust he had not yet succeeded in proving that the sericite content bore a direct relationship to the extent of the lesions.

Dr. H. R. SEAR (Sydney) submitted some notes on
Diagnosis of Bone Tumours

Early differentiation of the type of tumour was of great importance from the aspect of treatment. All available information, such as the history and the results of any pathological examinations, should be made available to the radiologist. A much more extensive X ray examination might be required than had been requested. For example, in a child referred for X ray examination the skull appeared to be normal but secondary neuroblastomata were observed in the femora. A typical history was obtained and the red cell count was found to be 2,670,000. A hopeless prognosis was given. The child was then taken to another physician and referred to another radiologist; the latter was only asked to X ray the skull which showed no abnormality. Two months later the child died. Again, a man referred for examination of a swollen and inflamed finger was diagnosed as having osteomyelitis. Six weeks later the patient died in another hospital with metastases from a Ewing's tumour. On re-examination of the original films with a magnifying glass there was a suggestion of a fine periosteal deposit arranged at right angles to the shaft.

Dr. Sear discussed bone tumours in four groups according to the part of the bone mainly involved—

that is, showing changes (a) mainly periosteal; (b) mainly cortical; (c) mainly central; (d) composite changes. In connexion with group (a) he discussed secondaries from primary bronchogenic carcinoma, extraperiosteal fibrosarcoma, secondary neuroblastoma, and the lacework type of specific periostitis. In group (b) the conditions causing most difficulty in diagnosis were hydatid, lymphadenoma, and certain metastases, such as hypernephroma. In group (c) showing central involvement there were four main lesions likely to cause errors in diagnosis: (1) hydatid (central type); (2) lipoid histiocytosis, the general massive type, also the changes described by Schuller in the skull and by Gaucher in the long bones—either one or both combined; (3) central cartilaginous masses (allied to Ollier's disease but not a true Ollier's disease); (4) secondary hypernephromata. The composite group, said Dr. Sear, was more complex, according to the following Table:—

Lesion.	Lesion to be excluded.
1. Ewing's tumour	.. (a) Osteomyelitis; (b) syphilis; (c) tuberculosis; (d) Garré's sclerosing non-suppurative osteomyelitis; (e) Engelmann's disease.
2. Paget's disease	.. (a) Supervention of sarcoma on same; (b) prostatic secondaries; (c) "ivory" vertebrae.
3. Lipoid histiocytosis (Gaucher's with massive destruction).	(a) Tuberculosis; (b) metastases.
4. Secondary neuroblastoma	(a) Osteomyelitis; (b) chloroma.

Dr. Sear showed numerous slides of X ray films to illustrate these conditions. He also drew attention to the comparative rarity of the supervention of sarcoma upon Paget's disease in Australia. In America 14 per cent. of cases of Paget's disease were reported to have developed sarcoma, in Germany 5 per cent., while his own figures only showed 2 per cent.

Dr. V. McDOWELL (Brisbane) stressed the importance of obtaining full clinical notes of cases, and pointed out that in some conditions a definite diagnosis could only be arrived at after observing the reaction of the tumour to deep therapy—e.g., Ewing's tumour. He considered that a comprehensive classification of bone tumours was needed to avoid the present confusion in nomenclature. He agreed that the incidence of sarcoma supervening on Paget's disease was not nearly so common in Queensland as it appeared to be abroad.

Dr. COLIN MACDONALD (Melbourne) agreed with Dr. Sear that it was the secondary deposit confined to one bone which caused mistakes in diagnosis. Such unusual bone changes were more frequently due to secondary carcinoma than to primary sarcoma. Most bone tumours were epiblastic in origin, although they were formerly considered to be mesoblastic. With regard to Ewing's tumour he said that at the Children's Hospital, Melbourne, during the last ten years he had only seen one completely proven case.

Dr. HOWARD PRAAGST (Melbourne) said that in his experience Ewing's tumour occurred most commonly in adults in the ribs. When it occurred in the long bones he found that the proportion in the tibiae to the tarsal bones was 15:1. Hydatid of bone was very rare in Australia, especially when compared with the frequency of hydatid cysts occurring in other parts of the body; in the last ten years only nine cases of bone hydatid had been seen at the Royal Melbourne Hospital. Dr. Praagst referred also to the frequency with which negative Casoni and complement-fixation tests were obtained in the presence of proven hydatid disease.

MEDICINE IN THE COLONIES

THE work of the Government medical services in the various parts of the British Commonwealth is of fundamental importance, and we are glad to see once more a supplement to the *Tropical Diseases Bulletin* which summarises in a single volume¹ the information contained in the various annual medical and sanitary reports from British colonies, protectorates, and dependencies. This supplement, the fifth of its kind, is fuller than previous issues, and contains an account of the activities of 55 medical services. The summaries follow the same general arrangement as before, giving for each colony the year's record of vital statistics, maternity and child welfare work, school hygiene, general sanitation, housing, and town-planning, followed by particulars of the incidence of the more important diseases and the measures taken locally to combat them. New features are the addition of short prefatory notes on the geographical positions and areas of the colonies concerned, and of a useful index of names and subjects.

MALARIA.

Of the major tropical diseases malaria presents the most urgent problem. Control measures suited to one region may prove quite unsuitable in other localities where circumstances and conditions are different. This difficulty is well illustrated by the experience in the Windward Islands where certain parts are mainly infested by anopheles breeding in the ravines, which are numerous. In times of heavy rain the larvæ are washed out to sea and the malaria incidence falls; in dry weather pools are left in the ravines and breeding goes on unimpeded. In the flat cane lands in the river valleys however quite the reverse holds good; here the greater the rainfall the higher the incidence. A different problem is present in Trinidad, where brackish water swamps are well-recognised zones of high endemicity. Here it was found that if sea-water was admitted to maintain the salinity at about 80 per cent. of "equatorial sea-water," breeding of anopheles ceased. The sanitary engineer therefore carried out work to replace the stagnant brackish water by moving sea-water in parts where reclamation by filling was impracticable; he notes however that wherever practicable the latter is the best method of eradicating anopheles breeding.

Antimalarial oils for use in anopheles control have been investigated in Kenya. Tests on oil fractions ("cracked" oil) indicate that the important larvicidal properties depend upon the presence of certain quantities and qualities of residue produced by distillation above 270° C. Borneo fuel oil appears to be slightly superior to Persian, and as a good spreader a mixture of Borneo fuel 10 parts and Solar oil 1 part is recommended in dosages of 18 to 20 gallons per acre at intervals of 7-8 days.

The question of the use of drugs other than quinine in malaria treatment and as a prophylactic in malarious centres has also been investigated. In the Federated Malay States Dr. R. T. B. Green has tested Atebrin to determine the advisability of substituting it for quinine in the treatment of malaria on rubber estates among ambulatory outdoor patients.

He concludes that "atebrin possesses the advantage that it can be given in a daily curative dose at one muster and is willingly taken by the labourers without fear of cinchonism." For ordinary general treatment however he sees no special advantage in its use in place of quinine. Dr. Green also tested totaquina which he found to be slightly less efficient than quinine in the immediate treatment of acute malaria. In Hong-Kong Quinoplasmoquine has been tried in place of quinine as a prophylactic in one of the New Territories police stations at Tsun Wan. During the half year of trial no case of malaria was admitted to hospital from this station, although of eight men who were transferred from it, and therefore ceased to take the drug, three subsequently went down with malaria.

SOMIASES

Work on trypanosomiasis has been carried on in most of the African Colonies. Preventive measures have mainly taken the form of mass treatment of the people and localised protective undertakings against the tsetse-fly. In East Africa control measures have been agreed upon by the governments of Tanganyika Territory and the Uganda Protectorate to prevent natives infected with *Trypanosoma rhodesiense* in Tanganyika from crossing over to Uganda. In Nyasaland the medical entomologist Dr. W. A. Lamborn has continued his investigations into the possibilities of vectors other than tsetse acting as transmitters of trypanosomes. His experiments with *Bdellolarynx latifrons* show that these flies are sufficiently long-lived for the development of trypanosomes within them and that their blood-feeding voracity adds immensely to their potentialities as carriers of disease-producing organisms.

Turning to diseases due to helminths, schistosomiasis is said to have been almost unknown in Bechuanaland before 1932, but in 1933 there was a widespread infestation among the tribal school-children at Mochudi, 101 children having contracted infection from residual pools in the Marico and Notwani rivers, the snails not having been washed away as usual because of a serious drought. By way of prevention, heglig berries (*Balanites aegyptiaca*), which abound in the endemic areas in the Sudan, have been found by Archibald to be lethal to the cyclops, the schistosome-carrying mollusc, without interfering with the potability of the water. In view of this observation these trees have now been planted round a village pond near Katsina in Nigeria and experiments are to be made there to test their efficacy in that part of Africa. Interesting and important research on schistosomiasis has been carried out by Dr. A. R. D. Adams in Mauritius where the intermediate molluscs have hitherto evaded discovery. Dr. Adams has shown that, under conditions resembling those present in nature in irrigation canals in Mauritius, *Bulinus forskali* thrived and became heavily infested with bifid-tailed cercariae, while none of the other species employed as controls were attacked. The evidence implicating this particular mollusc as carrier in Mauritius is therefore very strong.

The ophthalmic report from the Sudan contains an interesting account of investigations on "Sudan blindness" by Dr. Joseph Bryant who finds that this condition is a localised disease associated with people who live along rocky streams. Where "Sudan blindness" has been found there also *Onchocerca volvulus* has been found; but Dr. Bryant regards

¹ Tropical Diseases Bulletin, 1935, vol. xxxii. Supp. Medical and Sanitary Reports from British Colonies, Protectorates, and Dependencies for the Year 1933, summarised by H. Harold Scott, M.D., F.R.C.P., D.P.H., Director of the Bureau of Hygiene and Tropical Diseases. Pp. 280. 7s. 6d.

"Sudan blindness" and onchocerciasis as distinct entities with similar distribution, for in the former the condition is bilateral and night blindness is a constant symptom, whereas onchocercal keratitis is occasionally unilateral and in its early stages vision is better in poor light than in sunshine.

The supplement is full of meat; we have only been able to sample it, picking out an item here and there of special interest. The summary of vital statistics—birth, death, and infant mortality-rates—for each of the colonies, with the corresponding figures for the previous year; records progress and the whole provides a ready reference to the activities of the medical services under British rule. For the members of the Colonial Medical Service, past, present, and future, it is an indispensable handbook.

MEDICINE AND THE LAW

The Practitioner's Right to His Own Name

THE *British Medical Journal* has lately published several interesting letters on the grievance of practitioners whose names are used by manufacturing chemists. The correspondence began with a letter from Dr. Hugh MacLean. Some years ago he described in the medical press his method of treating certain gastric lesions by means of alkalis and he gave the formula of a powder which he had found efficacious in cases of gastric ulcer. He can fairly claim to have followed the best professional tradition in having made his conclusions and his experience available to all practitioners to be tested or used in the common interest. He had justifiable ground for annoyance when firms of manufacturing chemists made up and marketed a powder and took liberties with his name in advertising their wares. At his instance the B.M.A. made representations. Some firms abandoned the use of his name; others took no notice. His recent letter complains that one firm, Macleans Ltd., has lately issued a prospectus wherein it claims proprietary rights in the "Maclean Brand Stomach Powder"; the firm, he says, adopted this name for the powder after strong protests on his behalf had induced it to cease describing the powder as made up "according to the formula of Professor Hugh MacLean." He contends that members of the public will inevitably draw the entirely false inference that he is in some way financially interested in the manufacture and sale of the powder. He has apparently been advised that he has no legal remedy for his annoyance except a possible action for libel which, whatever its outcome, would involve him in expense, loss of time, and undesired publicity. He asks if it would not be possible to introduce legislation to prevent the exploitation by unscrupulous persons of a prescription published in the medical journals. As he observes, the widespread sale of a remedy prescribed for use in certain conditions may do harm if used in other conditions, and in any case it is grossly unfair that a similarity of name should enable a firm to claim some special virtue in the art of dispensing the powder whereof he published the formula. Other practitioners, it seems, have suffered similarly by the unauthorised association of their names with druggists' preparations. Has a professional man, they ask, no right to restrict the use of his name?

It is a great pity that the case of Dockrell v.

Dougall went the wrong way in 1899. The vendors of a liquid named "Sallyco" advertised that Dr. Morgan Dockrell was prescribing Sallyco as an habitual drink; "Dr. Dockrell," added the advertisement, "says nothing has done his gout so much good." Unfortunately the jury found that the words were not a libel. The plaintiff failed to obtain any finding that the words were likely to injure him in his profession, although it seems clear that the jury might have held that they suggested that he had violated professional ethics by lending his name to puff a remedy in which he had an interest. Dr. Dockrell then had to argue that he had a property in his name *per se*. Here the Courts were definitely against him. "If it could be made out," said Lord Justice Smith, "that a man has a property in his own name *per se*, and there has been an unauthorised use of his name, the plaintiff might be entitled to an injunction; in order, however, to be entitled to an injunction, it seems to me that the plaintiff must show injury to himself in his property, business or profession." If the case of *Dockrell v. Dougall* went the wrong way, the more recent case of *Tolley v. Fry* holds out some better hope. Mr. Tolley, a noted amateur golfer, was stupidly caricatured on the advertisement of a brand of chocolate. He obtained damages for libel on the ground that this use of his name reflected upon his amateur status, since it implied that he had, for reward, allowed his portrait to be used for advertising purposes and had thus prostituted his reputation as an amateur. In the House of Lords Lord Hailsham thought it would be open to a jury to assume that no reputable firm of chocolate-makers would have the effrontery and bad taste to take the name and reputation of a well-known man for an advertisement commending their goods without first obtaining his consent. Mr. Tolley held his verdict and the analogy might serve to secure a verdict for a medical practitioner whose name has been abused in circumstances which suggest that he has broken the ethical rules of his profession. Dr. Hugh MacLean's particular annoyance is the use of his name by a commercial firm of a similar name. Need he allege fraud if he seeks a legal remedy? Can he show that the firm's conduct is calculated to deceive? Or will the court pessimistically reply, as Lord Loreburn did in the *Dunlop* litigation in 1907, "I cannot speculate on the degree of unwariness which would induce the confusion necessary to support the appellants' case"? At the common law, according to Jessel, M.R., in *Merchant Banking Co. of London v. Merchants' Joint Stock Bank* (1878), anybody might use his own name for the purpose of trade, or he might trade under any fancy name he chose, "and the mere fact of somebody else having the same name and carrying on trade under that name does not prevent another from doing the same." In *Turton v. Turten* (1889) Lord Justice Cotton, after citing those words, added that "when a man knows that the natural consequences of what he is doing is to represent his goods as the goods of somebody else, then it is wrong on his part to continue that act." Presumably Dr. MacLean's main difficulty is that he is not a rival trader of Macleans Ltd. The Companies Act prohibits a company from being registered by a name which is identical with that of an already registered company or which so nearly resembles that name as to be calculated to deceive. A company, it has been decided, has not the same freedom to trade under a name already identified with an existing business as an individual might have. But unfortunately a medical practitioner has not the same rights as a

trading firm might have if he takes legal action to protect the use of his name.

Somehow it has happened that the law is ready to defend rights of privacy with alacrity where a plaintiff's property is concerned, but will give little help against interference with the personal seclusion of the plaintiff himself. Thirty years ago in *Corelli v. Wall* Miss Marie Corelli sought an injunction to restrain the defendant from selling (without her authority) coloured post cards containing indifferent portraits of her in imaginary incidents of her life. The court gave her no remedy either for libel or for the unauthorised publication of a bad portrait of herself. In *Tolley v. Fry* Lord Justice Greer had no doubt that the defendants, in publishing their advertisement without first obtaining Mr. Tolley's consent, were guilty of an act for which there ought to be a legal remedy. We can apply these words with emphasis to the act of which Dr. MacLean complains. There is probably a widespread feeling that the invasion of personal privacy requires to be checked. Public personages, politicians, and others may have to suffer the publicity which they sometimes move half-way to meet; the professional man, if he has no such ambitions, should have a right to his own name.

Fine for Unlawful Description as "Manipulative Surgeon"

The Paignton magistrates dealt on Nov. 15th with the case of Captain Horace Barrow which had been sent back to them by the Divisional Court (see THE LANCET, Nov. 2nd, 1935, p. 1023) with a direction to convict. They imposed a fine of £10 with an order to pay £10 10s. costs. In announcing the decision, the chairman of the bench remarked that their former decision had been reached by a majority and was contrary to advice tendered to them by the clerk to the justices. The magistrates, it may be recalled, had originally refused to convict and had awarded Captain Barrow a substantial sum for costs. This award the Divisional Court annulled.

MEDICAL MEN IN PARLIAMENT

WE miss some familiar faces from our Parliamentary gallery and there are no new ones. In two constituencies medical candidates were opposing one another: at Bury neither was successful; at Reading Dr. Howitt's success, which we all welcome, unfortunately means the defeat of Mr. Somerville Hastings, whose chairmanship of the chief health committee of London would in itself have qualified him for a place in the deliberative assembly. Many besides doctors will regret Dr. Addison's absence from the new House, and we offer sincere condolence to Dr. O'Donovan and to Sir John Worthington on their defeat at Stepney and the Forest of Dean. A number of men and women in active general practice put up plucky fights, but there are very few general practitioners among those who retain their seats. It looks as though Parliamentary life under existing conditions is not available for the practising doctor, however much it may be for the practising lawyer. Those who will represent medicine in the new Parliament cover all political parties and will continue to meet as a medical parliamentary committee under the chairmanship of Dr. Howitt.

ANALYSIS OF VOTING

The list of medical candidates here given shows the individual position at the poll and the number of votes registered. The sign † indicates membership of the last House of Commons, ‡ membership of a previous Parliament, and * that the candidate has contested this or some other seat before.

Constituency.	Name.	Position at poll.	Votes registered.
<i>Universities.</i>			
London	Sir Ernest Graham-Little†	1	(1) Nat. Ind., 8,958 (2) Lab., 3,918 C., Unopposed.
Queen's, Belfast..	Prof. T. Sinclair†		
<i>London Boroughs.</i>			
Bermondsey (West)	Dr. Alfred Salter†	1	(1) Lab., 12,603 (2) L. Nat., 7,674
Camberwell (Dulwich)	Dr. C. R. Cooke-Taylor*	3	(1) C., 16,870 (2) Lab., 7,142 (3) L., 3,743
Hammersmith (South)	Dr. J. D. Cooke†	1	(1) C., 15,377 (2) Lab., 9,399
Paddington (North)	Dr. G. de Swietochowski	3	(1) C., 17,153 (2) Lab., 9,925 (3) L., 1,795
St. Marylebone ..	Dr. Elizabeth Jacobs	2	(1) C., 31,183 (2) Lab., 8,008
St. Pancras (South-East)	Dr. S. W. Jeger	2	(1) C., 11,976 (2) Lab., 10,340 (3) L., 1,181
Stepney (Mile End)	Dr. W. J. O'Donovan†	2	(1) Lab., 13,177 (2) C., 8,839
Wandsworth (Central)	Sir Henry Jackson†	1	(1) C., 14,728 (2) Lab., 10,405
<i>English Boroughs.</i>			
Bury ..	Dr. Edith Summerskill	2	(1) C., 18,425 (2) Lab., 12,845
	Dr. D. McIntosh Johnson	3	(3) L., 6,065
Manchester (Rusholme)	Dr. Percy McDougall*	3	(1) C., 19,678 (2) Lab., 9,258 (3) Ind., 2,325
Newcastle-on-Tyne (West)	Mr. J. W. Leech†	1	(1) C., 25,326 (2) Lab., 17,082
Preston (2 seats)	Dr. R. A. Lyster*	3	(1) C., 37,219 (2) C., 36,797 (3) Lab., 32,225 (4) Lab., 31,827
Reading ..	Dr. A. B. Howitt†	1	(1) C., 27,540 (2) Lab., 22,919
	Mr. Somerville Hastings†	2	(3) L., 2,685
Smethwick ..	Dr. C. W. Brook*	2	(1) C., 16,575 (2) Lab., 15,023
Tynemouth ..	Dr. S. Segal	2	(1) C., 16,003 (2) Lab., 10,145 (3) L., 7,868
<i>English Counties.</i>			
Gloucester (Forest of Dean)	Sir John Worthington†	2	(1) Lab., 16,768 (2) Nat. Lab., 12,337
Herts (St. Albans)	Sir Francis Fremantle†	1	(1) C., 33,743 (2) Lab., 16,233
Lincoln (Horncastle)	Dr. H. C. Haslam†	1	(1) C., 17,594 (2) Lab., 7,982
Wilts (Swindon)	Rt. Hon. C. Addison†	2	(1) C., 20,732 (2) Lab., 19,757
<i>Welsh Counties.</i>			
Brecon and Radnor	Dr. L. Haden Guest†	2	(1) Nat. Ind., 22,079 (2) Lab., 19,910 Lab., Unopposed
Carmarthen (Llanelli)	Dr. J. H. Williams†

IRELAND

(FROM OUR OWN CORRESPONDENT)

PROPOSED PENSION SCHEME FOR NURSES

A Bill to establish a scheme of pensions for nurses and midwives was introduced to the Senate of the Irish Free State last week by Senator Dowdall, with the backing of Senator Sir Edward Coey Bigger among others. The Bill provides that a Pensions Endowment Trust is to be established by a sum of £250,000 out of the sums in the hands of the National Hospital Trustees which have accrued from the Hospitals Sweepstakes. Every nurse and midwife is to contribute 6d. a week toward a Nurses' Pensions Fund, and every hospital is to contribute 6d. a week to the same Fund in respect of every probationer nurse in training. To this fund will go also all interests, dividends, and income arising from the investment of the Pensions Endowment Trust. A nurse is defined as "a woman who has adopted nursing as her sole mode of livelihood and who is registered by the General Nursing Council of Saorstát Eireann," and a midwife as "a person who carries on no other occupation than that of midwife and who is certified by the Central Midwives Board of Saorstát Eireann." A period or periods in the aggregate of twenty years' work as a nurse or midwife is necessary for qualification for a pension, and the pension will begin when the nurse or midwife resigns her occupation. The amount of the pension will be £30 a year, or such greater sum as the Minister may from time to time determine.

Unfortunately it is the fact that it is more difficult for nurses to make adequate provision for old age than it is for other working women. In the first place the working life is shorter. A nurse at fifty or over, unless she has been fortunate enough to get into some permanent service, is likely to find herself both unemployed and unemployable. Again, despite the importance of their work to the community and the trying conditions in which much of their work is done, nurses are, in comparison with other working women, much underpaid. Hitherto the various charitable funds which have been got together to assist nurses in financial difficulty, while they have helped individual cases, have probably tended to perpetuate the practice of under-payment. It is doubtful whether a provision of pensions by such a scheme as is put forward in Senator Dowdall's Bill would not, in the event, do more damage than good to the interests of the nurses themselves by postponing the establishment of the work of nursing on such a financial basis as would enable nurses, like other skilled workers, to make provision for the time of their retirement. It is anomalous to set up a public scheme of pensions for one class of workers while other workers whose services are equally essential to the community have no such provision made for them. If such a scheme is to be set up it would seem fairer to endow it from public funds rather than from funds accumulated by the voluntary hospitals for the treatment of the sick. Already there have been too many inroads on the Sweepstakes Funds for purposes foreign to their original purpose. It is often forgotten that the sweepstakes were promoted and established by the authorities of the voluntary hospitals to provide funds for those hospitals. The Government contributed nothing, and in fact takes 25 per cent. of the proceeds in return for giving permission to promote the sweepstakes. In recent years it has also made the previously rate-

supported institutions parasitic on the scheme so far as building and improvements are concerned. There does not seem to be any justification for making other extraneous objects dependent on the Sweepstakes Funds.

BUCKSTON BROWNE DINNER

ROYAL COLLEGE OF SURGEONS OF ENGLAND

OF the two speakers at the Buckston Browne dinner at the Royal College of Surgeons on Nov. 14th the first was the president, Sir CUTHBERT WALLACE. The greatest event of the College year, he said, had been Sir Holburt Waring's journey to Australia to open the new buildings of the Royal Australasian College of Surgeons. Examiners for the primary fellowship had also travelled far afield, and 35 of 68 candidates had passed this examination last December in Australia and New Zealand, while 21 out of 60 had passed in Madras. This winter it was hoped to hold another examination in India. At home, with the Royal College of Physicians, diplomas had been instituted in anaesthetics and child welfare. Another memorable feature of the year had been the fate of the Osteopaths Bill in the House of Lords—a fate largely attributable, he thought, to the efforts of the College and especially of Mr. Elmslie, Mr. Souttar, and Dr. Graham-Hodgson. After speaking of the lecture and scholarship founded in memory of Sir Robert Jones, and of arrangements by which annual scientific meetings are to be held jointly by British and French surgeons alternately in France and this country, the president turned to changes in the College staff, including the appointment of Mr. A. J. E. Cave as assistant conservator of the museum and of Mr. L. W. Proger as pathological curator. He expressed, amid applause, the thanks of the College to Mr. T. W. P. Lawrence who retired from his post as acting pathological curator last March. The maintenance of the museum and of research were two of the main tasks of the College, he continued, and for the museum new specimens were urgently wanted: at present only about 150 specimens were received each year. In the department of research investigations on shock were being made which had been quoted far and wide; and—an encouraging sign—Dr. Beattie, the conservator, was getting applications for bench space from men overseas. Also one of the Beit fellows had been sent to work at the College. The laboratories on the top floor could and should be made perfect, and this could be done, with suitable endowment, at a cost of a mere £100,000. Meanwhile the research farm at Downe had proved of inestimable value.

Sir BUCKSTON BROWNE, when his health had been drunk, expressed his pleasure at seeing his guests. Medicine, he felt, was gradually coming into its own as the highest of professions—the highest because it is concerned with the human body from which all human activities spring. The nineteenth century must go down as the most important of all in the history of man because it brought a sense of the importance of the body. The world would never again be as it was in 1859 when the "Origin of Species" appeared: "man realised what he was, where he came from, and that he had prospects before him." The College of Surgeons had a fine tradition in biology, and the work of Hunter and Jenner had been continued by Arthur Keith. But formerly presidents and councils did not take much interest in this side of its work, and it was not until ten years ago that money was voted and rooms arranged for the more elaborate forms of biological research. It was then that those in charge began to long for the more spacious days of John Hunter when within two or three miles of Lincoln's Inn-fields, in lovely country, a farm could be found where experimental animals could be kept in healthy surroundings. This was where he had been able to

help. "The College," said Sir Buckston, "is a stern mistress. But at last she took me to her bosom, and although we were both of mature age the union has been fruitful and a strong and lusty child has been born." Already splendid work had been done at the research farm at Downe under the control of the president and council, the conservator, and the resident master, Sir Arthur Keith. He begged his hearers to go to the farm, see for themselves, and do their best to encourage public support for scientific research rather than for magic and superstition.

At the end of the dinner the president announced that those present included the "youngest member of the College," admitted that afternoon. This was Mr. Ernest Theophilus Roberts, M.D. Edin., 1889, who had attempted the Conjoint examination in 1886 but had only succeeded in passing in midwifery and medicine. During retirement Dr. Roberts had employed some of his leisure in preparing for the final surgical examination, and had that day completed it.

After the dinner there was an exhibition of letters written by John Hunter when he was naval surgeon with the Belle Île expedition. The guests then gathered in the lecture theatre where Dr. Beattie had arranged a cinematograph show including films of the vocal cords in health and disease and the first talking-pictures to be seen at the College. The film of the opening of the Buckston Browne Research Farm presented many familiar figures; but none so familiar, perhaps, as Felix the Cat, who concluded the entertainment.

The following is a list of those present:—

Council.—Sir Cuthbert Wallace (president). Prof. A. H. Burgess (Manchester), and Sir Charles Gordon-Watson (vice-presidents). Sir Holburt Waring, Prof. E. W. Hey Groves (Bristol), Mr. F. J. Steward, Mr. C. H. Fagge, Mr. W. Sampson Handley, Mr. Wilfred Trotter, F.R.S., Mr. Victor Bonney, Prof. G. Grey Turner, Mr. Hugh Lett, Mr. R. G. Hogarth (Nottingham), Prof. R. E. Kelly (Liverpool), Prof. Graham Simpson (Sheffield), Mr. A. E. Webb-Johnson, Mr. G. Gordon-Taylor, Mr. R. C. Elmslie, Mr. L. R. Braithwaite (Leeds), Mr. H. S. Souttar, Mr. W. Girling Ball, and Mr. Seymour Barling.

Fellows.—Mr. A. S. Blundell Bankart, Mr. L. R. Broster, Sir Buckston Browne, Mr. F. F. Burghard (Burton-on-Trent), Mr. H. Jackson Burrows, Mr. Robert Cooke (Bristol), Mr. R. K. Debenham (Birmingham), Mr. Harvey Jackson, Mr. R. Watson Jones (Liverpool), Mr. J. C. Leedham-Green, Mr. O. V. Lloyd-Davies, Mr. G. Percival Mills (Birmingham), Mr. John Morley (Manchester), Mr. W. G. Mumford, Mr. Lionel Norbury, Mr. Michael J. Smyth, Mr. W. G. Sutcliffe, Mr. H. W. Symons (Leeds), Mr. H. Bell Tawse (Nottingham), Mr. Cecil Wakeley, Colonel J. M. Weddell, Mr. James Whillis, and Mr. N. G. Wigram.

Members.—Dr. G. G. Allan, Mr. L. D. Bailey, Dr. Frederick Barker (Parkstone), Dr. P. G. A. Bott, Mr. Arthur Bulleid, Dr. F. G. Caley, Dr. A. E. Carver (Torquay), Mr. F. L. Cassidy, Dr. F. B. Chavasse (Liverpool), Mr. W. H. Coldwell, Dr. Macdonald Critchley, Dr. T. M. Davie, Dr. H. P. S. Devitt, Dr. T. F. Fox, Mr. C. R. Edwards, Dr. David Forsyth, Dr. E. P. Furber, Dr. Harold Gardiner-Hill, Dr. L. P. Garrod, Dr. A. Hope Gosse, Dr. Arnold Gregory (Manchester), Colonel A. E. Hamerton, Dr. T. L. Hardy (Birmingham), Dr. T. H. Harker (Southport), Mr. A. G. Hewer, Mr. C. T. Holford (Burton-on-Trent), Dr. N. G. Horner, Dr. J. B. Howell, Dr. J. T. Hunter, Dr. A. G. Maitland-Jones, Dr. Geoffrey Marshall, Dr. D. J. Martin (St. Leonards), Mr. William Neil MacLay, Dr. H. L. Oldershaw, Dr. T. Wilson Parry, Dr. Norman L. Price (Bristol), Mr. L. W. Proger (pathological curator), Dr. R. J. V. Pulvertaft, Dr. H. J. Roper (Leeds), Dr. M. Radford, Dr. E. T. Roberts (Glasgow), Dr. W. H. Scott-Easton (St. Mary Cray), Mr. E. T. Shorland (Westbury), Dr. J. H. Sheldon (Wolverhampton), Dr. G. Evan Spicer, (St. Albans), Dr. P. B. Spurgin, Mr. G. V. Steward (Fleet), Mr. Edgar Olive Turner (Great Missenden), Dr. G. de Bec Turtle, Mr. H. Stobie, Mr. H. S. Wachter, Dr. Cecil Wall, Dr. E. Welch (Leeds), and Dr. L. E. H. Whitty.

Others present.—Dr. J. W. McNee, Mr. H. H. Rev (secretary to the Examining Board), Dr. John Beattie (conservator and director of research), Mr. W. R. Le Fanu (librarian), Mr. Kennedy Cassels (secretary), and Mr. A. J. E. Cave (assistant conservator).

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Lt.-Comdrs. J. V. Williams to *Galatea*, and as Squadron M.O.; W. M. Greer to *Despatch*; and E. T. S. Rudd to *Victory*, addl. for R.N.B.

Surg. Lt. C. G. Owen to *Despatch*.

ROYAL ARMY MEDICAL CORPS

Lts. (on prob.) secd. under Art. 213. Royal Warrant for Pay and Promotion, 1931 (vide THE LANCET, Nov. 16th, 1935, p. 1146): W. N. L. Haynes, J. F. Wilson, J. R. Kellett, C. P. Stevens, J. H. Caverhill, K. G. F. Mackenzie, and J. A. Farfor.

TERRITORIAL ARMY

Supernumerary for service with the O.T.C.—Lt. H. R. Thompson to be Capt. Maj. J. Whillis (empld. Durham Univ. Contgt., Sen. Div., O.T.C.) resigns his commn. and retains his rank, with permission to wear the prescribed uniform.

Capt. N. H. Hammer to be Maj.

Capt. P. Malpas resigns his commn.

Lt. A. P. McEldowney to be Capt.

J. L. Swanston (late Cadet, Brighton Grammar School Contgt., Jun. Div., O.T.C.), to be Lt.

J. G. Scott (late Offr. Cadet, Glasgow Univ. Contgt. (Med. Unit), Sen. Div., O.T.C.), to be Lt.

T. Seager and C. K. Sconce to be Lts.

The King has conferred the Efficiency Decoration upon the undermentioned Officers under the terms of the Royal Warrant dated Sept. 23rd, 1930: Lt.-Col. J. F. O'Grady, and Maj. D. Stewart, R. J. W. A. Cushing, A. C. MacDonald, M.C., and W. A. Jackman.

ROYAL AIR FORCE

Flight Lt. A. H. Barzilay relinquishes his commission on appointment to a permanent commission in the Indian Medical Service.

Dental Branch.—Flight Lt. R. H. Matthews to R.A.F. General Hospital, Himaidi, Iraq.

INDIAN MEDICAL SERVICE

Col. E. C. Hodgson, D.S.O., retires.

Lt.-Col. J. Scott, D.S.O., O.B.E., Surgeon to the C.-in-C., is proceeding on leave and vacates his appointment.

The undermentioned appts. are made:—

Majs. to be Lt.-Cols.: S. Nag; J. Rodger, M.C.; and G. B. Hanna.

To be Capt. (on prob.): A. H. Barzilay, R. K. Muir, and P. M. McSwiney.

To be Lts. (on prob.): J. A. L. McCullough, D. J. P. Parker, C. L. Ash, T. C. McG. Morrison, V. D. Gordon, B. de Burca, D. R. Nicol, J. Morgan, and T. Sommerville.

Lts. C. K. Byrnes and G. F. Adye-Curran are restd. to the Estbt.

Cpts. A. M. Khan, P. P. Chowdry, H. K. Handoo, P. N. Sathe, D. N. Basu, and H. S. Ahluwalia relinquish their temp. commns.

COLONIAL MEDICAL SERVICE

Dr. R. Calderwood, Miss M. H. James, M.B., and Dr. A. L. Shield have been appointed Medical Officers, Malaya; Miss V. R. Sharp, M.R.C.S., Medical Officer, Zanzibar; and Miss S. M. Young, M.B., Medical Officer, Health Department, Palestine.

PARKES MEMORIAL PRIZE.—Surgeon-Lieutenant J. L. S. Coulter, R.N., has been awarded the Parkes Memorial prize for 1935, for his essay on preparation for tropical service in the Royal Navy. The prize is awarded annually to the writer of the best essay on a subject connected with naval or military hygiene.

PANEL AND CONTRACT PRACTICE

Compromising Silence

A PATIENT'S widow told the following story to a medical service subcommittee. Her husband, who had been treated by Dr. A. for rheumatism over a period of three months, was in extreme pain on a particular Sunday. She called at the surgery that evening and saw Dr. A., who said he would call next morning and did not. Her husband being still in pain she went again on Monday evening for the doctor who called at 7.30 P.M. He made no physical examination, advised the patient to continue to take the medicine already prescribed and to remain indoors pending a further visit. The pain did not abate and on the following Thursday the wife went to the surgery and rang two or three times without obtaining a reply. Another doctor was called in, who found the man suffering from pleurisy. A third doctor arranged for his admission to hospital, suffering from rheumatic fever and pleurisy, where he remained for some weeks, dying about two months after his discharge. Dr. A. never saw the patient again, nor did he respond to any letters addressed to him by the committee which makes the following comment:

"In the absence of any communication whatsoever from the practitioner we decided to accept in its entirety the statement made by the complainant, who appeared to us to be a witness of truth. The practitioner has made no attempt to refute any of the statements made by the complainant. There was, of course, no legal obligation on the respondent either to answer letters addressed to him by the Committee or to attend before us, but he could hardly expect his conduct in this respect to produce a favourable impression. This is in itself a serious indication of a lack of any sense of responsibility in the general conduct of his practice, and he has only himself to thank if thereby he has been deprived of the opportunity of presenting his conduct in relation to this case in a less unfavourable light than that in which we have been compelled to view it."

It may be that the doctor had a perfectly good answer in reply to his alleged failure to provide treatment for an insured person, but he will now be asked by the Ministry of Health to explain not only this but his attitude to the committee, and runs the risk of removal from the medical list. It seems a pity.

The Thumb which Went Wrong

The suggestion is sometimes made that the proceedings of medical service subcommittees savour of Star Chamber methods. Reference was made in this column recently to a case in which the committee commented in no unmeasured terms upon the attitude of the employer of an insured person by whom a complaint was raised against a doctor. The discussion in a northern insurance committee on a case of alleged neglect, with the eventual necessity for the terminal phalanx of an insured person's right thumb to be amputated, suggests that the doctor gets a fairer hearing in the mixed committee than he would if a committee of laymen conducted the investigations. A patient consulted his doctor in February, 1935, for a slight injury to his thumb which was found to be septic. The doctor incised and drained the thumb, gave instructions about the treatment and prescribed ointment and bandage. The patient attended at the surgery on the next three days and received appropriate treatment and subsequently further treatment was provided either by the doctor or one of his partners at intervals of not less than seven days. Early in the course of treatment the doctor suggested

the desirability of an X ray of the thumb, but his partner thought it unnecessary. On June 4th the patient asked for an X ray and the report disclosed that the bone was diseased. The patient thereupon attended hospital and received treatment there almost daily for three weeks, his thumb being incised and drained on two occasions. He did not, however, see his insurance doctor. Later the patient was told by the house surgeon at the hospital that amputation would be necessary, but on July 1st he left Lancashire for the South Coast where on July 6th a portion only of his thumb was amputated. The committee while expressing sympathy with the insured person at the loss, suffering, and expense he had sustained were of opinion that the doctor had not failed to exercise reasonable care and skill in the treatment of the patient.

A member of the insurance committee criticised the constitution of the subcommittee and said that having read their report he thought someone outside the district ought to give a verdict thereon. He did not think it was right to have three doctors sitting on this subcommittee. Another member pointed out that cases of this kind might seriously affect a number of people in the town and he contended that it should have been dealt with by the full committee. Accidents were happening every day, but most of them were cured in a day or two. Here was a man who had gone through suffering, had lost his thumb which handicapped him in his employment, and had been put to heavy cost to get correct treatment. If the treatment had been correct he would have been back to work within a week. Nevertheless the report of the subcommittee was adopted with a single dissident.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
NOV. 9TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2742; diphtheria, 1330; enteric fever, 26; acute pneumonia (primary or influenzal), 781; puerperal fever, 28; puerperal pyrexia, 110; cerebro-spinal fever, 11; acute poliomyelitis, 19; encephalitis lethargica, 6; relapsing fever, 1 (Dorking and Morley R.D.); dysentery, 25; ophthalmia neonatorum, 76. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on November 15th was 3189, which included: Scarlet fever, 1180; diphtheria, 1239; measles, 62; whooping-cough, 221; puerperal fever, 21 mothers (plus 11 babies); encephalitis lethargica, 280; poliomyelitis, 7. At St. Margaret's Hospital there were 14 babies (plus 3 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 28 (1) from measles, 2 (0) from scarlet fever, 8 (1) from whooping-cough, 26 (3) from diphtheria, 46 (12) from diarrhoea and enteritis under two years, and 38 (7) from influenza. The figures in parentheses are those for London itself.

Liverpool reported 9 deaths from measles, Manchester 8, Bootle 4, and Tynemouth 2. Deaths from diphtheria were scattered over 23 great towns, Birmingham reporting 2, no other town more than 1. The mortality from influenza is similarly scattered over 29 great towns, only Liverpool, Middlesbrough, and Swansea reporting 2 deaths, no other great town more than 1.

The number of stillbirths notified during the week was 234 (corresponding to a rate of 38 per 1000 total births), including 39 in London.

CORRESPONDENCE

RESECTION FOR CARCINOMA OF THE
SIGMOID AND SIGMOID RECTUM*To the Editor of THE LANCET*

SIR,—In your issue of Nov. 16th Dr. D. P. MacGuire describes an operation for cancer of the rectum which I feel should not be allowed to pass without criticism, especially at the present time when surgeons in this country are striving to simplify operations of this type and reduce the mortality. The operative procedures used in England for removal of cancerous tumours of the upper end of the rectum and lower end of the pelvic colon are now more or less standardised, and although, no doubt, still capable of considerable improvement are a great advance on similar operation of 20 years ago. The operation as described in Dr. MacGuire's article seems a clumsy and unnecessarily complicated procedure with nothing to recommend it. Most surgeons of the present day, myself included, prefer to do the operation in two stages, as it has been found from experience that the safety of the patient is much increased thereby and the immediate mortality lowered. This is also the opinion of many American surgeons, including those of the Mayo Clinic. The colostomy is established at the first operation and the resection performed at the second operation, after a suitable interval to allow of the colon being decompressed and the patient brought into the best possible condition. Moreover, the time which the operation takes, necessarily rather long, is considerably shortened by planning the operation in two stages.

The method of first freeing the rectum from below and completing the resection from the abdomen was first described by Mr. W. B. Gabriel (*THE LANCET*, 1934, ii., 69) and has advantages both in saving time and making the operation easier. The combined operation, starting in the perineum, only involves one move, from the left lateral to the back position, whereas the procedure described by MacGuire involves at least two moves. In my experience there is no danger in dividing the colon at the first stage of the operation, and although I have done it a considerable number of times I have had no sepsis or peritonitis result from it. There are often adhesions which require separating, but this slight disadvantage is being got over, and in any case is more than outweighed by the greater safety of a two-stage operation, and the much shorter time that the operation takes. I have this last week done a complete second-stage combined operation in a man in 50 minutes, including the time taken in turning the patient and changing gloves.

Blood transfusion is called for only occasionally and I have never known it necessary to use more than one, while parotitis as a complication I have yet to meet with.

An operation that must of necessity be performed upon an elderly patient (since cancer of the rectum is usually met with in patients between the ages of 55 and 65) must, to be successful, be as simple and as quick as is reasonably possible, and an operation which inevitably involves opening the abdomen three times (twice through one incision and once through another), and also opening the pelvis from the perineum, cannot, it seems to me, recommend itself to modern surgeons, and is not one to be copied.

I am, Sir, yours faithfully,

J. P. LOCKHART-MUMMERY.

Harley-street, W., Nov. 15th.

SKIN TESTS FOR WHOOPING-COUGH

To the Editor of THE LANCET

SIR,—In your issue of August 17th last (p. 361) a preliminary report on a skin test for pertussis was published by Drs. Bailey, Waller, and myself. Since then I have been doing further skin tests, and using Sauer's vaccine as an antigen. The results obtained vary with the batch, and it appears to me that the ideal and constant antigen has not yet been achieved. I hope that someone working at this subject will be able to produce a really satisfactory and constant antigen for the intracutaneous skin test.

I am, Sir, yours faithfully,

DONALD PATERSON.

Devonshire-place, W., Nov. 15th.

"KWASHIORKOR"

To the Editor of THE LANCET

SIR,—Under the above title there appears in your last issue (p. 1151) an article by Dr. Cicely Williams with the sub-title "a nutritional disease of children associated with a maize diet." May I firstly enter a protest against the use of a West African native word as the title of an article. How will it be possible for anyone later looking for references to nutritional disorders to recognise one under such a designation? The secondary title is equally open to criticism as it would seem that the association with a maize diet is merely incidental. There is a further objection to the name *kwashiorkor*; it indicates "the disease the deposed baby gets when the next one is born." That such a sequence of events occurs is a common superstition in other parts of Africa as I first pointed out in 1922 (*Harvard African Studies*, vol. iii., p. 289). Among the Wa-yao of Central Africa the disease, whatever it may be, is called *litango lya kututa*—each successive child is said to push (ku-tuta) the previous one into its grave.

In Dr. Williams's previous article (1933) a number of statements were made in regard to the differential diagnosis between this disease and pellagra, which were calculated to give an entirely false impression of pellagra and I felt constrained to draw attention to them the following year (*Arch. Dis. Childhood*, 1934, ix., 115). Dr. Williams has now again repeated these misstatements in regard to pellagra, presumably based upon a failure to realise the course and symptomatology of that disease, and tends to confuse the problem at issue. To deal with the table of "Differences between Kwashiorkor and Pellagra":—

1. The affected skin is "black, rugose, and soft" in K. So it may be in typical P. Elsewhere Dr. Williams states it "tends to peel off, leaving a moist, raw surface." This is often the case in P. and while branny desquamation may take place in P., in other cases large ulcerated areas may result.

2. "Extensor surfaces and points of irritation and pressure affected" in K. This of course is common in P. As I have pointed out elsewhere any form of trauma, in its wide sense, may determine the site of the pellagrous eruption. The distribution of the skin affection in K. is probably what one would expect.

3. "Skin not photosensitive" in K.—photosensitive in P. In P. the skin is not always photosensitive. In the West African children it is not proved whether or not the conditions necessary for the exhibition of photosensitivity were present or not.

4. K. "occurs in children under 5 years"—usually under 2 years. P. "rare in children, almost unknown under 2 years." This is a fallacious statement. Pellagra may

occur at any age—a child of a few months, a centenarian—provided the conditions necessary for its production are present.

5. "Reflexes unchanged" in K.: "peripheral neuritis common" in P. It is obviously quite beside the point to compare infants suffering from the acute disease of short duration with more chronic cases of P. with involvement of the nervous system. One would hardly expect to see changes of the reflexes in Dr. Williams's babies.

6. The same is true of dementia—a symptom seen in old chronic pellagrins. Does Dr. Williams seriously consider the absence of dementia in these babies a point of differential diagnosis!

7. The presence or absence of a milk diet is of little importance per se; the point would be the quality of the milk.

8. The same is true of yeast—why compare the yeast-contaminated maize product with the curative effects obtained by the exhibition of large doses of certain yeasts?

Let this suffice in the way of criticism and turn to the positive side of the picture. A typical skin eruption occurring in areas subject to trauma, associated with stomatitis, sores at the muco-cutaneous junctions and vulva (so common in pellagra as I pointed out many years ago), diarrhoea, and nervous irritability—the picture of pellagra—the picture, of pellagra to be expected in the infant.

I am, Sir, yours faithfully.

London, W., Nov. 17th.

HUGH S. STANNUS.

DELAYED LACTATION

To the Editor of THE LANCET

SIR,—The Truby King school has taught us never to despair of restoring breast-feeding. I should like to ask: How long after the birth of a child is it possible to restore a discontinued supply of breast milk, and after what period of discontinuance?

A Chinese woman, aged 21, was delivered with forceps by a local practitioner under dirty conditions in the village of Yenangyaung on Jan. 24th, 1935. She had a bad perineal tear and developed severe puerperal sepsis for which she was admitted to hospital on Feb. 6th. After a few stormy weeks she was finally discharged from hospital on April 14th, having had no fever for a week but still suffering from a high degree of secondary anaemia. Her condition continued to improve after discharge from hospital and in about two months she was quite well apart from the unrepaired perineal tear. No attempt was made to suckle the baby during this period, and there was no sign of milk in the mother's breast after admission to hospital. When the infant was 12 weeks

old it was admitted to hospital for a severe attack of vomiting and diarrhoea due to faulty feeding—partly with sweetened condensed milk and partly wet-nurse's milk. When it recovered from this it was sent home with explicit instructions as to bottle-feeding.

No news was heard from the family until the end of July, when the child developed influenza, and on inquiry as to feeding, it was announced that a few weeks after discharge from hospital at the end of April, the mother had begun to put the child to the breast, and in two weeks had been able to dispense with bottle-feeding and feed the child entirely from the breast. Needless to say, it was fed in the good old Asiatic fashion—i.e., whenever it cried.

The point of interest in this case is that the mother had produced no milk for three months after confinement and then became able to feed her child entirely from the breast—and this in spite of a trying illness in which her life hung in the balance, and which produced a severe secondary anaemia. Further, there was no attempt at regular intervals of feeding, and the only lactagogue used was a much advertised wine.

It would be interesting to know whether cases of this type are common in the experience of paediatricians.

I am, Sir, yours faithfully,

W. B. CRAWFORD.

B.O.C. Hospital, Nyaungghla, Upper Burma.

A KIND THOUGHT

To the Editor of THE LANCET

SIR,—I shall be obliged if you will allow me a small space in your columns in order that I may express our thanks to a number of German-Jewish doctors who have been compelled to leave their country and to take refuge in this country. In the midst of their difficulties and distress they have collected in small sums over £10 for the Royal Medical Benevolent Fund. They have asked us to accept it as a thank-offering for the kindness and hospitality that has been shown to them and their unfortunate countrymen by England. I think that this kind thought on their part for our poorer brethren merits something more than the official acknowledgment of the contributions; hence this letter.

I am, Sir, yours faithfully,

L. G. GLOVER,

Hon. Treasurer, Royal Medical Benevolent Fund.
11, Chandos-street, London, W.1, Nov. 18th.

OBITUARY

CHARLES HERMANN TATTERSALL, M.R.C.S.,
D.P.H.

Dr. Tattersall, who died at New Milton, Hants, on Nov. 11th, was for many years medical officer of health for Salford. He qualified at Manchester from Owens College in 1886 and became medical officer to the Barton-upon-Irwell Union; then after taking the Durham diploma in sanitary science he was appointed medical officer of health for Eccles, Oldham, and finally, in 1897, Salford. He lectured on public health at Owens College, examined in the Victoria University, and advised the Salford education committee. The work of the Salford health department during his tenure grew enormously and was transferred from the town hall to the building where it now is. Dr. Tattersall saw a large proportion of the pail closets in the city converted to water carriage and most of the back-to-back houses transformed by through ventilation. He started an open-air school in Peel Park and, after its manifest success,

another at Barr-hill, Pendleton. In one aspect of public health work, at least, Dr. Tattersall was well ahead of his time, for, from the commencement of his service in Salford he carefully fostered the work of the Ladies' Public Health Society, a voluntary organisation existing solely for the welfare of mothers and children. Under Dr. Tattersall's administration, from this elementary coöperation was developed, by degrees, a service established on a wider and firmer footing, so that it became a simple matter in 1915 to create a fully fledged maternity and child welfare department, when these activities became generally recognised.

Tattersall was a sound chemist. His inquiry at Oldham into the plumbo-solvent action of the local water was a fine piece of work, but it was in the astonishing outbreak of arsenical poisoning from beer in 1900 that he came to public notice. The acumen of the late Dr. E. S. Reynolds saw something to be investigated in the increasing number of cases of "alcoholic paralysis" admitted to the Manchester

Royal Infirmary, and he actually discovered arsenic in the beer they had been drinking. But it was Tattersall who worked indefatigably to trace the origin of the arsenic and who found the clue in a sample of the sulphuric acid used in making the glucoses and invert sugars supplied to the brewers. His evidence satisfied the Royal Commission on Arsenical Poisoning, held the following year, that the epidemic was due to the use of a particular sugar in the making of beer. Tattersall had noted the great rise in the deaths from alcoholism and peripheral neuritis between June and November, 1900, and the increasing number of patients reported from the poor-law hospital to be suffering from what appeared to be alcoholic neuritis. Numbers of cases of herpes zoster were also being reported. He ascertained that all the sufferers took beer, and was impressed by the fact that many of them had not been excessive drinkers, the amount of beer consumed varying from 1 to 16 pints a day. While the preliminary examination of the beer by Delépine was in hand they heard of Dr. Reynolds's discovery and were able at once to confirm it. In Salford alone there were 107 deaths and 996 reported cases of neuritis; Tattersall had no doubt many more cases had occurred and had been concealed to avoid the stigma of excessive drinking. No cases of illness resulted from the consumption of confectionery or jams or syrups containing glucose, the sufficient explanation being that the invert sugar and glucose were supplied by the works in question only to brewers. It was Tattersall's experience of this outbreak which aroused his keen interest in the possible adulteration of food and drugs, which resulted later in the appointment of a whole-time public analyst for Salford.

Throughout his official life Dr. Tattersall met every new task with energy and the ability of a born administrator; perhaps the best tribute to his work is the fact that so little criticism could be levelled against anything he undertook. He was an excellent pianist and organist, and after his retirement his home was the centre of a musical circle.

GEORGE WILSON BURN, M.R.C.S.Eng., L.S.A.

Dr. Wilson Burn, who died at Cromer on Nov. 11th in his eighty-ninth year, has left an account of his

life in a volume of "Stories and Recollections" circulated among his friends a few months ago. He was, he tells us, born a cripple, but his uncle, Adolphus Burn, who practised in Bow and afterwards in Australia, divided his tendo Achillis (tenotomy was then a new operation) with the result that he was able to walk if need be 30 miles in the day. The scarpa shoe which he wore for six months is in the museum of the Royal College of Surgeons under his name. Young George went to school at Newport Pagnell and then at Great Linford, where his paternal grandfather was schoolmaster and where he learnt Latin grammar by heart without the least idea of what it meant. Life in rural Buckinghamshire then had its attractions. There was the circus, there was Wombwell's menagerie, and there was the Long Fair at which Prof. Pepper demonstrated the ancient ordeal by fire. His other grandfather had practised as a doctor in Limehouse all his life—it was owing to his effort that the water in that area was turned on for half an hour every day instead of once a week—and George had always wanted to be a doctor, although his father was anxious for him to go into a bank. But he got his way and after passing the London preliminary scientific from home he entered Bart.'s with a scholarship in October, 1868, where he found two subjects very prominent in the public eye—viz., antiseptics and bone-setting, and came under the spell of James Paget and Lauder Brunton. He clerked for Samuel Gee and dressed for G. W. Callender. After qualifying in 1873 he set up in practice in Brixton, going his rounds in a hansom cab. His wife was a district visitor in the borough and he remained in general practice until 1901 when he retired to St. Albans and later to Cromer. Always interested in botany, most of his time was devoted to gardening, the remainder to popularising Esperanto—a task which took him to many international conferences. His life, he tells us, taught him that at some time or other our words and deeds have been influenced by the words and deeds of someone else who may have been long dead. Hence it behoves us so to speak and to act that any such unconscious influence may be good and beneficial. It was on this principle that Dr. Burn himself acted during his nearly 90 years.

MEDICAL NEWS

University of Cambridge

The following have been appointed examiners:—

Second Examination for M.B., 1936.—Anatomy: Prof. H. A. Harris, Prof. Thomas Walmsley, and (if required) Dr. W. L. H. Duckworth and Dr. Archibald Durward. Physiology: Mr. F. J. W. Roughton, Ph.D., Dr. E. G. T. Liddell, and (if required) Dr. O. A. Trowell, Prof. B. A. McSwiney. Pharmacology (including oral): Prof. E. B. Verney, Dr. Clifford Hoyle, and (if required) Dr. G. W. Theobald, Dr. G. N. Myers, Dr. K. J. Franklin, and Prof. A. St. G. Huggett. General Pathology: Dr. E. T. C. Spooner, Prof. M. J. Stewart, and (if required) Dr. L. E. H. Whitby, Dr. Raymond Williamson, Dr. H. A. Lucas, and Dr. G. P. McCullagh.

Qualifying Examinations, 1936.—Anatomy: Dr. Duckworth, Prof. Walmsley. Physiology: Dr. F. R. Winton and Prof. J. B. Leathes, F.R.S.

Third Examination for M.B., 1936.—Surgery: Mr. Geoffrey Keynes, Mr. A. Tudor Edwards, Mr. R. Davies-Colley, Mr. J. B. Hunter, Mr. W. H. Osilvie, and (if required) Mr. W. S. Perrin, Mr. Julian Taylor, Mr. Sampson Handley, Mr. Geoffrey Jefferson, Mr. Lancelot Bromley, Mr. W. H. Bowen, Mr. R. M. Vick, and Mr. Ivor Back. Midwifery: Dr. Wilfred Shaw, Mr. Stanley Dodd, Dr. Malcolm Donaldson, Mr. William Gilharr, and (if required) Mr. L. Carnac Rivett, Dr. J. M. Wyratt, Dr. J. R. C. Canner, Mr. V. B. Green-Armytage, Mr. Aleck Bourne, and Mr. Frank Cook. Medicine: Dr. G. S. Haynes, Dr. A. E. Clark-Kennedy, Dr. George Graham, Prof. A. E. Naish, Dr. Arnold Stott, and (if required) Dr. Geoffrey Evans, Dr. Crichton Bramwell, Dr. J. W. McNee, and Dr. C. E. Lakin. Pharmacology, Therapeutics, and Toxicology: Prof. Verney, Dr. T. H. Oliver, and (if required) Prof. W. J. Dilling, Prof. E. D. Wilkinson, Prof. J. H. Burn, and Dr. Leslie Cole.

On Nov. 15th the following degrees were conferred:—

M.D.—D. B. Wilson.
M.B., B.Chir.—D. P. King.
M.B.—R. W. Ironside and C. W. Thomas.
B.Chir.—N. C. London.

* By proxy.

The Royal Society

The list of names to be recommended for election to the council of this society on Nov. 30th contains the following: president, Sir William Bragg, O.M.; treasurer, Sir Henry Lyons; secretaries, Sir Frank Smith and Prof. A. V. Hill; foreign secretary, Prof. A. C. Seward. The council is to include Prof. E. D. Adrian, F.R.C.P., Sir Patrick Laidlaw, F.R.C.P., Prof. Robert Robison, and Mr. Wilfred Trotter, F.R.C.S. The Davy medal has been awarded to Prof. Arthur Harden for his work on biochemistry and especially for his fundamental discoveries in the chemistry of alcoholic fermentation.

Harveian Society of London

The Buckston Browne prize for 1935 has been awarded to Dr. W. R. Fearon, of Trinity College, Dublin, for his essay on nutritional factors in disease.

Birmingham General Hospital

Sir Herbert Austin has given £2000 to this hospital for the provision of a third X ray apparatus.

Royal College of Surgeons of England

A meeting of the council was held on Nov. 14th, with Sir Cuthbert Wallace, the president, in the chair. Mr. Victor Bonney was re-elected representative on the Central Council for District Nursing for a period of three years. The council decided to guarantee a sum of £1625 from the Proffit trust towards the expenditure of the governing body of Radium Beam Therapy Research for the year beginning next March.

Diplomas of membership were granted to the candidates named on p. 1094 of our issue of Nov. 9th as receiving the L.R.C.P. (except T. D. Chablani, Bishnupada Datta, E. W. Knowles, and Phyllis J. M. Sykes). A licence in dental surgery was granted to Tord Borke, and diplomas in public health and child health were granted jointly with the Royal College of Physicians to the candidates named in *THE LANCET*, Nov. 9th, p. 1094. Diplomas in anaesthetics were granted jointly with the Royal College of Physicians to L. M. Routh and S. T. Rowling.

The following hospitals were approved, with the posts specified, for recognition for the six months' surgical practice required of candidates for the final fellowship examination:

Cumberland Infirmary, Carlisle (senior house surgeon);
St. George's Hospital, London (1st, 2nd, and 3rd assistant
and 1st, 2nd, 3rd, and 4th house surgeon);
St. George's Hospital, Greenwich (resident surgical officer
and 1st and 2nd house surgeon until July 31st, 1937).

British College of Obstetricians and Gynaecologists

At a meeting of the council held on Nov. 16th with Dr. J. S. Fairbairn, the president, in the chair, the following were elected to the membership: P. A. McCleod, C. M. Plumptre, T. R. Plunkett, and H. Rowntree.

A. A. Gemmell (Liverpool) was formally admitted to the fellowship and the following to the membership:—

Bernard Berger, G. A. Davies, F. J. Hayden, A. M. Hill, J. L. Jona, Alice M. Kenny, Hilda N. Lloyd, H. I. McClure, L. B. Patrick, T. G. Robinson, G. R. Sparrow, G. R. Stoneham, Jane B. Stubbs, W. E. C. Thomas, C. K. Vartan, and Ramsay Warden.

Ahmed Bey Shafik (Cairo) was admitted to the foundation fellowship in absentia, and the following were admitted to the membership in absentia:—

Narendranath Basu, J. R. S. Beard, James Black, J. H. Boyd, W. G. Cosbie, H. D. De Sa, K. C. Donovan, M. B. Fraser, Israel Goldberg, A. F. Hobson, J. S. Howell, T. D. Hughes, J. Jhirad, Hilda M. Lazarus, D. M. Low, Ronald McRobert, G. B. Lowe, R. E. Magarey, A. A. Moon, E. L. Newman, Hemendranarayan Ray, Ida B. Saunders, T. H. Small, R. S. Townsend, H. B. Van Wyck, and James Waterman.

At the end of the meeting, Sir Ewen Maclean assumed the office of president. A vote of appreciation of the services of Dr. Fairbairn during the past three years as president was adopted by the council.

ANNUAL DINNER

The presidents of both sister colleges supported the president of the British College of Obstetricians and Gynaecologists at the fifth dinner of the college, held at Claridge's on Nov. 15th. It was Dr. Fairbairn's leaving-taking of the presidential chair; on Saturday he was to surrender it to Sir Ewen Maclean. Lord Dawson, in giving the toast of "The College," spoke of its founder and first president, the restless lovable torch-bearer who never forgot—or allowed anybody else to forget—that he was bearing a torch; "and now," he said, "after six years you have a membership of which you may be proud, and you have brought the old country and the new together in a fresh bond of service." The college had come to the front at a time when the public was beginning to look for help to the medical profession; for with the rationing of babies they were coming to depend on quality rather than quantity, more than when there was a bigger turn-over. Speaking of the dangers of maternity, Lord Dawson said he wanted the public to realise that quite as much depends on the house, and on the state of the mother before birth, as on her condition during and after it. In the co-operation growing up between medicine and local health authorities, he begged the college to keep the lead in its own hands in guiding the maternity service. In their search for a means of relieving pain which could safely be put in the hands of the midwives themselves he asked them to refuse to be hustled. Finally he congratulated the college on its good work. It had initiated

post-graduate study, it had gained a standing in the world, it had shown leadership in public health policy, and it had fostered fellowship the world over. The colleges would now move forward in a spirit of co-operation.

Dr. Fairbairn in reply rejoiced that both the senior colleges were there. In these early years the principles on which the obstetric college should base its work had gradually crystallised out. The problem of analgesia in childbirth was, he thought, proving more difficult to solve than had been thought; the committee's report on it was to be presented to the council on the morrow. The estimate of cost had been found grossly inadequate, particularly in the cost of gas inhalation, where he hinted at leakage. Dr. Fairbairn had brought back with him from Australia the greetings of Prof. Marshall Allan and his colleagues at Melbourne. There were, he said, two outstanding events during his overseas visit: the admission of 17 new Australian members, and a luncheon given by the foundation fellows in Australia—a real family party. Not having time to visit New Zealand he had asked Mr. Bright Banister to delegate there for him, and he had found the same enthusiasm for the college. At home the internal work was going on. They had revised the articles and the by-laws. The rising curve of membership showed as yet no sign of falling off.

Sir Ewen Maclean gracefully proposed the guests and Sir Cuthbert Wallace replied, speaking of the debt he owed to Dr. C. J. Cullingworth who, he said, took the gynaecological knife out of the surgeon's hands. The dinner concluded at an early hour when the floor was cleared for dancing, there being many young people present.

Royal Faculty of Physicians and Surgeons of Glasgow

At the annual meeting of the faculty on Nov. 4th the following were elected office-bearers for the ensuing year:—president: Prof. Archibald Young; visitor: Dr. John Henderson; hon. treasurer: Mr. James H. MacDonald; hon. librarian: Dr. W. R. Snodgrass; other councillors: Mr. G. H. Edington (representative to the General Medical Council), Dr. Carstairs Douglas, Dr. A. Brown Kelly, Mr. John Patrick, Mr. Roy F. Young, Mr. R. Barclay Ness, Mr. J. Forbes Webster, Mr. John Gracie, Dr. J. Souttar McKendrick, Mr. John Rowan, and Mr. A. G. Faulds.

The honorary higher dental diploma was conferred on Mr. J. Forbes Webster, dean of the Incorporated Glasgow Dental Hospital.

Royal Sanitary Institute

The next health exhibition of this institute will be held at Southport in July, 1936, in connexion with its annual health congress. Further information may be had from the secretary at 90, Buckingham Palace-road, London, S.W.1.

Medical Society of Individual Psychology

At a meeting of this society on Nov. 14th Dr. J. A. Hadfield gave an address entitled a Contribution to Psychopathology. He suggested that a working basis of psychopathology was possible which was independent of the hypothesis of sexual libido as a primary urge; upon the elaboration or perversion of which subsequent equilibrium would depend. This basis was provided by an investigation into the infant and child life in relation to maternal protection and love. He suggested that such investigation would provide the necessary help to the understanding of many of the neuroses and psychoneuroses. Anxiety and other emotional states and the many psychoneuroses such as hysteria and delinquency appeared often to be related to the deprivation of protective love rather than to sexual repression on the one hand, or organ inferiority on the other. The specific symptom was, he suggested, conditioned by the state of mind of the child at the time of deprivation; and such a state of mind was often determined by the age and stage of development of the child. Thus depression, sex perversions, and anxiety states usually originated in the first year of life, obsessional states in the second year (or aggressive phase), conversion hysteria about the age of three, and delinquencies in the phase of independence at four.

Central Housing Advisory Committee

Under the Housing Act, 1935 the Minister of Health has appointed a committee to advise him on questions of housing. He will himself be chairman, and the members will be Lord Balfour of Burleigh, Sir Harold Bellman, Mr. G. M. Burt, the Earl of Crawford and Balcarres, Mrs. M. M. Dollar, J.P., the Earl of Dudley, Sir Francis Fremantle, M.D., M.P., Miss Megan Lloyd George, M.P., Mr. George Hicks, Mr. A. L. Hobhouse, J.P., Mr. L. H. Keay, F.R.I.B.A., the Countess of Limerick, Mr. O. Ling, J.P., Sir Miles Mitchell, J.P., Mr. C. J. Newman, Mr. E. G. Rowlinson, J.P., Sir Isidore Salmon, M.P., the Rev. E. St. G. Schomberg, Mr. L. Silkin, L.C.C., Mr. J. A. Simpson, Sir Raymond Unwin, F.R.I.B.A., Mr. J. A. F. Watson, Sir Seymour Williams, Dr. J. Greenwood Wilson, and the Bishop of Winchester. The secretary is Mr. H. H. George, to whom communications may be addressed at the Ministry of Health.

Battersea General Hospital

On Nov. 19th, in the Chancery Division, an alteration of the objects of this hospital was made by eliminating from them clauses relating to vivisection, as a result of which serums and antitoxins can now be used. For the last three years the hospital has had a large deficiency, but it will now be eligible for assistance from the King Edward Hospital Fund.

THE QUETTA EARTHQUAKE

LIST OF AWARDS

AMONG honours conferred for services rendered in connexion with the recent earthquake in Baluchistan are the following:—

C.I.E.

Lieut.-Colonel Samuel George Steele Haughton, M.D. Dub., O.B.E., I.M.S.
Officiating A.D.M.S., Zhob (Independent) Brigade Area, Western Command.

O.B.E. (Civil)

Lieut.-Colonel Vaman Raghunath Mirajkar, F.R.C.S. Eng., I.M.S.
Professor of Operative Surgery, King Edward Medical College, Lahore, Punjab.

O.B.E. (Military)

Lieut.-Colonel Jacob William Vanreenen, M.B., F.R.C.S. Edin., I.M.S.
Officer commanding No. 4 Company, Indian Hospital Corps, Quetta.

Kaisar-i-Hind Gold Medal

Mrs. Constance Ellice May Berridge, M.B. Glasg.
Lady Divisional Superintendent, Moghalpura Nursing Division, North-Western Railway Corps.

Major James Ernest Gray, M.B. Belf., I.M.S.
Civil Surgeon, Karachi, Bombay.

Kaisar-i-Hind Silver Medal

Miss Ruth Hooton, M.B. Leeds.
Of the Church of England Zenana Missionary Society.

Miss Nora Proctor Sims, M.R.C.S.
Of the Women's Medical Service, India.

Henry Bowlby Tristram Holland, M.B. Edin.
Of the Church Missionary Society.

Arthur Durnford Iff, M.R.C.S.
Of the Church Missionary Society.

Captain Bertrand Temple-Raston, L.M.S.S.A., I.M.S.
Civil Surgeon, Dera Ghazi Khan, Punjab.

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Nov. 25th.

Otolaryngology. 8 P.M. Mr. J. Draper Cambrook: Snake Venom. Mr. F. N. Doubleday: Two Unusual Cases of Impacted Lower Third Molars. Paper: Dr. T. H. Roper-Hall: The Barbiturates: their Chemistry, Action, and Toxicology.

Tropical Diseases and Parasitology. 8.30 P.M. Dr. Magarinos Torres: Further Studies on the Pathology of Alastrim and their Significance in the Variola-alastrim Problem. (Lloyd Roberts lecture).

TUESDAY.

Medicine. 5 P.M. Sir Edmund Spriggs: The Causes and Treatment of Obesity. Followed by Dr. H. Gardiner-Hill and Dr. Donald Hunter.

WEDNESDAY.

Comparative Medicine. 5 P.M. (Lister Institute, Chelsea Bridge-road, S.W.).—A. S. McFarlane: 1. Spinning-top Centrifuge and 2. Mechanism. C. L. Oakley: 2. Tumours of the Kidney in F

Edwards: Transmission of Human Acute Coryza to Hedgehogs. H. Burrows: Pyelitis of Pregnancy considered in the Light of Conditions Occurring in Mice after the Prolonged Administration of Oestrone. D. W. Henderson: Passive Immunisation against Experimental Vibrio Septique Infection.

THURSDAY.

Urology. 8.30 P.M. Mr. E. W. Riches: 1. Urethrogram of Prostatic Diverticulum. Mr. James Carver: 2. Calculi in a Vesical Diverticulum in a Woman. 3. New Growth of Kidney with Ulceration of Bowel. 4. Congenital Maldevelopment of Kidney. 5. Large Pelvic Cyst producing Acute Retention of Urine in a man of 65. Mr. Malcolm Baillie: 6. Sections of Epididymomata. Mr. A. E. Roche: 7. Hemato-nephrosis and Carcinoma of the Renal Pelvis. Mr. H. P. Winsbury-White: 8-10. Urethral Calculi. Mr. T. E. Hammond: 11. Adenoma of the Kidney. Mr. Hamilton Bailey: 12. Total Cystectomy by Hinman's Method. 13-14. Plastic Operation for Pelvic Hydronephrosis. Mr. R. H. O. B. Robinson: 15. Radiograms Illustrating Double Ureter and Renal Plexus of Veins.

FRIDAY.

Obstetrics and Gynaecology. 8 P.M. Dr. D. Coutts: Foetus Removed from Mother's Thigh after Rupture of Uterus. Dr. Arthur M. Hill: Post-abortion and Puerperal Gas-gangrene, report of thirty cases. Dame Louise McIlroy: Atresia of the Vagina: Operation followed by Pregnancy and Caesarean Section. Dr. Ida Hirschmann: Derangement of Cyanide Metabolism—the Cause of Pregnancy Toxemia.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.
MONDAY, Nov. 25th.—8.30 P.M.—Dr. R. D. Lawrence and Dr. George Graham: The Use and Abuse of Insulin.

MEDICO-LEGAL SOCIETY.

THURSDAY, Nov. 28th.—8.30 P.M. (Manson House, 26, Portland-place, W.). Dr. F. J. McCann: Some Medico-legal Problems in connection with Pregnancy and Parturition.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY, 49, Leicester-square, W.C.

WEDNESDAY, Nov. 27th.—4.15 P.M., Clinical Cases. 5 P.M., Dr. L. Forman: Rosaceous Tuberculide.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Thorn-haugh-street, W.C.

Fever Group.

FRIDAY, Nov. 29th.—4 P.M., Dr. E. H. R. Harries: Fever Hospital Practice in Retrospect and Prospect (presidential address).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Nov. 25th, to SATURDAY, Nov. 30th.—INFANTS HOSPITAL, Vincent-square, S.W. Mon., Wednes., and Fri., 8 P.M., course in anatomy and physiology for the F.R.C.S. (primary).—LONDON LOCK HOSPITAL, 91, Dean-street, W. Afternoon course in venereal disease.—INFANTS HOSPITAL, Vincent-square, S.W., afternoon course in diseases of infants.—ST. MARK'S HOSPITAL, City-road, E.C. All-day course in proctology.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars, S.E. Afternoon course in dermatology.—BROMPTON HOSPITAL, S.W. Sat. and Sun., course in chest diseases.—Courses are open only to members of the fellowship.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Nov. 29th.—9.45 A.M., Mr. Norbury: Treatment of Carcinoma of the Rectum. 11.30 A.M., Dr. Rorke: Some Cases of Venereal Disease, and their Treatment. 2 P.M., Miss Barry: Treatment of Varicose Veins and

Hæmorrhoids by Injection. 3 P.M., Dr. Nicol: Psychological Medicine.

SATURDAY.—9.45 A.M., Dr. Davies: Anæmia. 11.30 A.M., Dr. Ulysses Williams: X Ray. 2 P.M., Dr. Ledingham: New Drugs. 3 P.M., Prof. Webb: Immunisation with Toxoids.

SUNDAY, Dec. 1st.—10 A.M., Prof. Amy Fleming and staff of Unit: Obstetric Lecture-demonstrations, including anaesthetics in midwifery practice.

The course is open only to former students of the hospital.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Nov. 25th.—3.30 P.M., Dr. Greenfield: The Chemistry of Cerebro-spinal Fluid.

TUESDAY.—3.30 P.M., Dr. Critchley: Epilepsy and Allied Conditions.

WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.

THURSDAY.—3.30 P.M., Dr. Walshe: The Motor System (II.).

FRIDAY.—3.30 P.M., Dr. Gordon Holmes: Disorders of Vision (II.).

Out-patient clinic daily at 2 P.M.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Nov. 28th.—2 P.M., Mr. G. G. Penman: Abnormalities and Diseases of the Eye in the Young Infant. 3 P.M., Dr. D. N. Nabarro: Congenital Syphilis (I.).

Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M. (except on Wednesdays).

CHARING CROSS HOSPITAL, W.C.

THURSDAY, Nov. 28th.—5 P.M., Prof. Edward Mellanby, F.R.S.: The Rapid Advance of Science since the Time of Huxley. (Huxley lecture.)

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.

THURSDAY, Nov. 28th.—3 P.M., Dr. Wilfred Harris: Pains about the Head and Neck.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, Nov. 27th.—4.30 P.M., Dr. H. N. Webber: Anaesthetics in Urology.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, Nov. 25th.—10 A.M., skin clinic, medical wards. 11 A.M., surgical wards. 2 P.M., surgical and gynaecological wards, gynaecological and eye clinics. 4.15 P.M., Dr. Maurice Shaw: The Truth about Peptic Ulcer.

TUESDAY.—10 A.M., medical wards. 11 A.M., surgical wards. 2 P.M., throat clinic. 4.15 P.M., Dr. Owen: Hemorrhage and Jaundice in Infants.

WEDNESDAY.—10 A.M., children's wards and clinic, medical wards. 2 P.M., eye clinic. 4.15 P.M., Mr. Woodd Walker: Diseases of the Hip-joint.

THURSDAY.—10 A.M., neurological and gynaecological clinics. Noon, fracture clinic. 2 P.M., eye and genitourinary clinics. 4 P.M., venereal diseases.

FRIDAY.—10 A.M., skin clinic. Noon, lecture on treatment. 2 P.M., throat clinic.

SATURDAY.—10 A.M., children's and surgical clinics, medical wards.

The lectures at 4.15 P.M. are open to all medical practitioners without fee.

Operations, medical and surgical clinics daily at 2 P.M.

KING'S COLLEGE HOSPITAL, Denmark Hill, S.E.

THURSDAY, Nov. 28th.—9 P.M., Mr. V. E. Negus: Tuberculosis of the Ear, Nose and Throat.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.

WEDNESDAY, Nov. 27th.—4 P.M. (St. James' Hospital, Ouseley-road, S.W.), Dr. Russell J. Reynolds: Cine-radiography.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, N.W.

WEDNESDAY, Nov. 27th.—4 P.M., Dr. P. Finigan: Aims and Methods of Modern Dentistry.

LONDON SCHOOL OF DERMATOLOGY, 49, Leicester-square, W.C.

TUESDAY, Nov. 26th.—5 P.M., Dr. R. T. Brain: Virus Diseases of the Skin.

THURSDAY.—5 P.M., Dr. Knowsley Sibley: Electro-therapeutics.

ST. JOHN CLINIC, Ranelagh-road, S.W.

FRIDAY, Nov. 29th.—4.30 P.M., Dr. C. A. Robinson: The Use of Diathermy in Some Menopausal Syndromes.

ROYAL INSTITUTION, 21, ...

TUESDAY, Nov. 26th.—5.15 P.M., Dr. Mellanby, F.R.S.: Modern Vic lectures.) of four

UNIVERSITY OF SHEFFIELD.

FRIDAY, Nov. 29th.—3 P.M. (Royal Hospital), Dr. E. Fretson Skinner. 3 P.M. (Royal Infirmary), Dr. Robert Platt: Medical Cases. 3 P.M. (Jessop Hospital), Prof. John Chisholm: Gynaecological Cases.

SUNDAY, Dec. 1st.—10.30 A.M. (Royal Hospital), Dr. E. Fretson Skinner: Medical Cases. 10.30 A.M. (Royal Infirmary), Dr. Robert Platt: Medical Cases. Mr. Alan Fawcett: Surgical Cases. 10.30 A.M. (Jessop Hospital), Mr. Eric Stacey: Gynaecological Cases.

GENERAL INFIRMARY, Leeds.

TUESDAY, Nov. 26th.—3.30 P.M., Dr. Bibby: Some Aspects of Congenital Syphilis.

PUBLIC DISPENSARY, Leeds.

WEDNESDAY, Nov. 27th.—4 P.M., Mr. L. X. Pyrah: Differential Diagnosis of the Acute Abdomen.

ANCOATS HOSPITAL, Manchester.

THURSDAY, Nov. 28th.—4.15 P.M., Dr. A. Renshaw: Asphyxia.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE EAR, NOSE, THROAT AND CHEST, Harman-street, Manchester.

WEDNESDAY, Nov. 27th.—4.30 P.M., Mr. V. F. Lambert: Dysphagia.

ROYAL INFIRMARY, Manchester.

TUESDAY, Nov. 26th.—4.15 P.M., Mr. W. R. Douglas: Carcinoma of the Pelvic Colon.

FRIDAY.—4.15 P.M., Mr. Wilson Hey: Demonstration of General Cases.

ST. MARY'S HOSPITALS, Manchester.

THURSDAY, Nov. 28th.—4.15 P.M. (Whitworth-street West Hospital), Dr. Gerrard: Some New Methods in the Diagnosis and Treatment of Obstetric Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, Nov. 27th.—4.15 P.M. (Royal Maternity and Women's Hospital), Prof. S. J. Cameron: Contracted Pelvis.

Appointments

ALLEN, E. H., M.R.C.S. Eng., has been appointed Physio-therapist to the Willesden General Hospital.

CRAWFORD, J. H., M.R.C.S. Eng., Hon. Assistant Anaesthetist to the Hove Gen

McKENNY, C. W., M radiologist to St. John's Hospital

MORLAND, ANDREW, M.D., M.R.C.P. Lond., Tuberculosis Officer at University College Hospital.

PRICE, R. KEMMALL, M.D. Lond., Hon. Physician to the Hove General Hospital.

ROSENKRANZ, L.R.C.P.E tant Radiologist to t

SMITH, S. LEVY, M.D.C to the Willesden Ge

King's College Hospital.—The following appointments are announced:—

EVANS, P. R., M.B. Manch., M.R.C.P. Lond., Registrar to the Children's Department and Medical Officer in charge of the Rheumatism Clinic;

JOHNSTON, C. M., M.B., Registrar to the Ear, Nose, and Throat Department;

PLAYFAIR, P. H. L., M.B. Camb., F.R.C.S. Eng., Obstetric Registrar and Tutor; and

SMITH, E. J., M.B. Lond., F.R.C.S. Eng., Surgical Registrar.

London County Council Hospital Staff.—The following appointments and promotion are announced. A.M.O. (I.) and (II.)=Assistant Medical Officer, Grades I. and II.:

ROBERTSON, J. S., M.D. Aberd., D.P.H., Senior A.M.O. (II.), Pinewood Sanatorium;

MILLER, O. P., M.B. Lond., A.M.O. (I.), Queen Mary's, Sidcup;

IRVINE, D. F., M.B. Glasg., House Physician, Hackney;

O'Riordan, J. D., M.D. Irel., A.M.O. (I.), Queen Mary's Hospital for Children;

WILEY, V., M.D. Irel., D.P.H., Senior Medical Officer;

BOOME, E. J., M.B. Birm., M.R.C.P. Lond., D.P.H., Principal Assistant Medical Officer; and

MITMAN, M., M.D., M.R.C.P. Lond., D.P.H., D.M.R.E., Divisional Medical Officer.

Births, Marriages, and Deaths

BIRTHS

BESLEY.—On Nov. 14th, at Great Shelford, Cambs, the wife of Surgeon Lieut.-Com. F. W. Besley, R.N., of a son.

BLAIN.—On Nov. 8th, at Edinburgh, the wife of Dr. J. A. Blain, Ardersier, Inverness-shire, of a son.

DEATHS

BROWN.—On Nov. 18th, in London, John Macdonald Brown, M.D. Edin., F.R.C.S. Eng., J.P., formerly of 64, Upper Berkeley-street and Leamington Spa.

BURN.—On Nov. 11th, at Roughton, Cromer, George Wilson Burn, M.R.C.S. Eng., L.S.A., in his 89th year.

BUTT.—On Nov. 12th, at a Bournemouth nursing-home, Colonel Edward Ormiston Butt, R.A.M.C., eldest son of the late John Gillis Butt.

GRANT.—On Nov. 18th, at Bedford Court Mansions, W.C.1, A. A. Cumming Grant, M.B. Glasg., in his 84th year, Chief of the Gaelic Society of London.

MALLESON.—On Nov. 12th, Herbert Cecil Malleson, M.R.C.S. Eng., L.D.S., of Thurlow-road, N.W., aged 51.

McKENZIE.—On 19th Nov., 1935, at 22, Hampstead-lane, N.6 (and of 9, Weymouth-street, W.), Dan, the dearly loved husband of Dora Christine McKenzie, aged 66. Cremation at Golders Green on Friday, Nov. 22nd, at 12.30. No flowers by request.

ROBERTSON.—On Nov. 12th, accidentally killed, Katherine Octavia Robertson, M.D. Glasg., of Limavady, aged 44 years.

TATTERSALL.—On Nov. 11th, at New Milton, Hants, Charles Hermann Tattersall, M.R.C.S. Eng., D.P.H., L.S.Sc. Durh., many years Medical Officer of Health for Salford.

WOOD-MARTIN.—On Nov. 10th, suddenly, at Cleveragh, Sligo, Annette Kathleen Wood-Martin, M.B. Dub.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE AMERICAN MATERNITY
HOSPITAL *BY K. VERNON BAILEY, M.C., M.D., M.R.C.P.,
M.C.O.G.HON. GYNECOLOGIST TO ANCOATS HOSPITAL, STOCKPORT
INFIRMARY, AND ALTRINCHAM GENERAL HOSPITAL;
LECTURER IN OBSTETRICS AND GYNECOLOGY IN
THE UNIVERSITY OF MANCHESTER

In a recent visit to Canada and the United States I went over some of the principal hospitals of Montreal, Chicago, and New York, and was received with a courtesy and kindness I shall always remember. Of the six large obstetrical units in these three centres five are less than five years old, and my object in this paper is to give some account of arrangements nowadays made in American hospitals which have been planned, built, and staffed apparently regardless of expense. They represent something new in medical achievement.

Of the six I visited the Chicago Lying-in Hospital is the only one wholly devoted to obstetrics and gynaecology, and it is interesting to find that while it maintains a regular staff it is open to outside practitioners, more than 150 of whom deliver patients there. At all the hospitals most of the patients contribute at least a large proportion of the cost of their upkeep, and there is always spacious accommodation for private cases—usually on a separate floor rather than in a separate block. Roughly speaking, women in the "semi-public" wards, usually 4-bedded, are charged 30s. per week; "semi-private" patients in 2-bedded rooms £3 per week; and private patients £6 upwards.

As one would expect, an atmosphere of general cleanliness is immediately evident from the spacious entrance hall onwards. Quiet is maintained by the use of electrical staff signals from the reception office to the ward corridors, rubber composition flooring, and the installation of sound-proof doors and ceilings to all labour rooms and theatres. The main office in the entrance hall is adequately staffed by clerks, stenographers, and telephonists, as is also the records department. The strictly obstetrical staff has ample assistance in all the ancillary departments.

The Antenatal Clinic

The conduct of antenatal clinics is well illustrated at the Chicago Lying-in Hospital. Here the patients collect in the main out-patient hall from which five separate doors communicate with a long passage. Five senior nurses—one at each door—each call the names of two patients, who proceed through a door into the intervening passage where they are checked by the nurses. They then walk straight into dressing cubicles—which abut in pairs upon the opposite side of the passage—and lock the doors upon themselves. They disrobe, put on a special gown and emerge from the opposite door of the cubicle into the examination room which thus deals with two patients. Here the house surgeon or intern carries out the routine antenatal examination assisted by another intern or student who completes the notes of the case. The patient then returns by the same route to the main hall. By this routine there is a minimum of movement on the part of all concerned. There is privacy for the patient and adequate space and light for the examining doctor and his assistants and students. Moreover, a large number of patients can be examined in this way without loss of time.

At the Royal Victoria Hospital, Montreal, the patient is given a printed card which she takes to a series of examiners (students or nurses) placed at different parts of the clinic. At each of these details

are acquired and entered on the card, so that when she arrives on the examination table the history, present weight, blood pressure, urine test, cardiac condition, and so forth are known.

A clinical laboratory is attached to the antenatal clinic as are also rest rooms for the patients who need them.

Admission and Preparation

The admission and preparation rooms, situated near the ambulance entrance, are, I consider, one of the most important parts of the obstetrical unit, in so far as they deliver the newly admitted patient to the wards in a clean and prepared state and militate against contamination of the hospital by dirty clothing or unsuspected infections. They have plain tiled walls and stone floors, and their chief furniture is a large fixed porcelain "preparation bed" with shallow raised edges and drainage grooves. On this the patient is washed and prepared, an enema apparatus being arranged in conjunction with the bed. The room also contains lavatory accommodation, shower and fixed douche. An adjoining examination room has appliances for testing the urine and blood pressure, as well as clinical facilities for obstetrical and general examination. All patients pass through these rooms and none are admitted to the wards until their condition has been thoroughly investigated.

Wards and Delivery Theatres

The wards themselves tend more and more to small size. They seldom contain more than six or eight beds and usually only three or four, the advantage being if infection develops its spread can be more readily stopped. A favourite design includes lavatory and bathrooms situated between two of these small wards with entrance from each. Furnishing varies, but there are many innovations. For instance, the St. Mary's Hospital at Montreal is very proud of full-length lockers or small ward-ropes let into the walls in groups of two or three, the metal doors being flush with the wall when closed. Each patient has a locker, and clothes and other belongings take up no floor space in the ward.

The solarium is a regular institution. It is placed as a rule at the more pleasant end of each ward, according to view or sun, and consists of a spacious glass-protected area furnished as a rest room. There is no doubt that the patient's comfort during the puerperium and the question of the beneficial effect of sunlight and variety is studied to the full.

The lying-in wards are all on the same floor, the labour wards and theatres being on a separate floor. In this way quiet is ensured to the patients during puerperium or pending their own labour. Corridor floors are of composition rubber and interrupted every 15 yards by swing doors which prevent the conduction of noise.

The labour floor comprises a series of first-stage single rooms and delivery theatres. The patient in early labour is removed from the ward or admitted straight to one of the first-stage rooms. This is simply furnished as a single room and is provided with a sound-proof door and ceiling. Delivery is carried out in the delivery theatres—of which the Chicago Lying-in Hospital has five. These are built and furnished as modern operating-theatres with the exception that a special delivery table is installed. This is simply a modification of the standard operating-table in which quick adaptation from the flat to the lithotomy position is acquired by unhooking and removing the foot end. Sound-proofing is carried out in all delivery theatres, and students' galleries are chiefly situated above the theatre floor and protected by an inclined glass screen. No one but the theatre staff, therefore, occupies the actual floor.

Theatre fittings include Crane's evacuator (used in Cesarean section), electric infant resuscitator, etc.

* Abridged from a paper read before the North of England Obstetrical and Gynaecological Society on Oct. 25th.

electric incubator, electric clock which signals every $\frac{1}{4}$ minute (for assistance in counting the foetal heart sounds), and at St. Mary's Hospital electric foot-operated tables. Forrigger's anæsthetic apparatus is largely used—a mixture of ethylene and gas being favoured.

Situated at one end of the theatre floor the *isolation unit* contains five or six single rooms, an examination room, a small clinical laboratory, and its own delivery theatre. All cases which are either obstetrically or generally infected are admitted to this unit and dealt with there.

Other Departments

Laboratories are numerous, and there is every facility for rapid and efficient testing in immediate conjunction with the clinical work. In the Chicago Lying-in Hospital there is a small clinical laboratory on each floor, and in all the hospitals there is a main clinical laboratory as well as a biochemical laboratory and a morbid anatomy laboratory. These are all very fully staffed by trained female technicians and controlled by a pathologist or biochemist. The routine is to cut all sections in wax and to mount a number from each specimen. Biochemical research as well as routine work is carried out.

The *sterilising departments* are unusually interesting at the Chicago Lying-in Hospital. Theatre sterilising is of course carried out on the main theatre floor. There is, however, a basement department under the control of a specially trained sister which deals with all materials necessary for the wards. Here drums containing dressings and the like are sterilised, and cupboards containing rows of shelves are specially provided for the reception of materials which may be needed at any moment in the wards. Sterilised linen parcels containing trays with all the necessities for dressings, gastric lavage sets, intravenous sets, and materials for vaginal examination—any of these will be sent up by the special elevator as soon as a telephone message is received. Numerous sealed, labelled, and dated flasks of saline solution of varying sizes and strength and of Ringer's solution are likewise kept in readiness in this department.

The *infants' nurseries and kitchens* are of uniform type. The infants are kept in single cribs or groups of four mounted on rubber-wheeled trollies in a centrally placed nursery, of which each ward floor has one. The nursery has a glass front abutting on to the corridor and a small section which may be raised for conversation between the sister and anyone in the corridor. The infants' kitchen adjoins the nursery, and each infant has its own tray bearing its own appliances.

The infants are wheeled into the wards for feeding only. The mother is taught the special care of the hands and breasts and handles her baby only at this time. After feeding, it goes back at once to the nursery. The patient's husband and friends are not allowed to touch it while it is in the hospital; they view it through the glass wall of the nursery. Incidentally no child under the age of fifteen is allowed to visit the patient. Apparently the public are quite used to these regulations and appreciate their significance.

An *isolation nursery* comprised of four or five small single rooms is provided for those suspected of infection.

A *doctor's rest room* is always provided. This is placed on the delivery floor and is furnished as a bed-sitting room with adjoining shower and bath. Here the obstetrician may rest during the time he is engaged upon a case of labour in the hospital.

Record-keeping

The hospital records are most scrupulously kept. A large staff of clerks is engaged for the purpose and special departments allotted.

At the Royal Victoria Hospital, Montreal, all the case-sheets, out-patient notes, &c., are collected when the patient is discharged and a summary of

them is typed separately and filed. Later these are bound according to dates.

The Chicago Lying-in Hospital has separate elaborated note-sheets for the antenatal clinic, which comprises history, physical examination, obstetrical and progress sheets, as well as a special one for urine examination and blood examination. A detailed record sheet containing all possible subdivisions of the pathological states of the various systems is used and those appertaining to the particular patient marked off. Ward note-sheets are separate for the obstetric admission record, labour progress record, mother record, mother and child's identification record, and nursing record.

In the New York Hospital I was struck by the pathological record system. All specimens are kept for a minimum of five years (in case of legal difficulties). Large cabinets filled with trays of slides are placed in conjunction with bound files containing the pathological notes. A card-index system at once reveals the number of the gross specimen and slide connected with the pathological notes. It also shows the number of the associated clinical notes in the clinical record office. In a matter of minutes therefore—as was demonstrated to me—all the notes with the specimens and slides can be obtained in any case which has been operated upon during the last five years. At the end of this time certain discards are made, but many specimens are kept longer. Naturally adequate room and staff is necessary for records such as this to be kept.

The Chicago Lying-In Hospital keeps a large ribbed felt board in the resident's sitting-room upon the surface of which is registered day by day the statistics of the work done. Monthly and yearly records are photographed and filed.

Details and Impressions

In this communication I have tried to indicate what seemed to me the salient features of these large American hospitals. One cannot help but leave them with impressions so numerous as to be almost kaleidoscopic.

A number of minor arrangements appealed to me greatly. The honorary has his own private study in the hospital where he may retire in peace to conduct his correspondence or to interview visitors to the hospital. Assistants are numerous and well trained—occasionally permanent. The details are thought of and carried out for the operator; the energy output in operating is, therefore, much less than with us. Again, it was pleasant to find that close collaboration with the university faculties is maintained.

Many details, though interesting, did not attract me so much. A special oxygen room is provided in the Passavant Hospital, Chicago, in which cardiac or pneumonia cases are placed at high expense. An electrically controlled water-heating apparatus is part of the infant nursery in the St. Mary's Hospital. This ensures an immediate flow of water, heated to any required temperature, by turning an indicator on a dial. During delivery in the lithotomy position at the Passavant Hospital any blood lost runs down a metal channel into a receiver below the table. This is fitted with a plunger which registers on a vertical manometer fitted to the table the amount of hæmorrhage. This factor is correlated with the state of the blood pressure.

The nursing staff appear to enjoy a higher status than in this country. Floor supervisors correspond to ward sisters. The individual task is more highly specialised.

The cafeteria system is used for nurses' meals. Patients' meals are sent in bulk from the main kitchens to floor "serveries," where carving and distribution is carried out. The service is therefore good.

Finally, I trust that in setting down these notes I have not inadvertently conveyed the impression of dissatisfaction with our own maternity hospitals:

in so far as I know them. The majority of these are old and financially limited, whereas some of the work in America is done under wellnigh ideal conditions. But, possibly, advantages spring from the necessity to make the best of circumstances, and it may be that we in this country are compensated by the development of a kind of sixth sense which makes up for other deficiencies, in our routine and operative work at any rate.

APPLICATIONS OF PSYCHOLOGY TO MEDICINE

PSYCHO-ANALYSIS and psychotherapy in general were the subject of an address given by Dr. William Brown, Wilde reader in mental philosophy in the University of Oxford, at a meeting of the Blackpool Division of the British Medical Association on Nov. 13th.

Dr. Brown began his lecture by explaining that he himself was not a Freudian but had used the Freudian method among others for over twenty years. At the same time psycho-analysis, a treatment which might extend to 60 or 100 hours or more, could not be afforded by many patients, and in his view, despite the fact that orthodox Freudians threw up their hands at the idea of suggestion treatment, there was no necessary conflict between the full analysis and "short-cut" methods in the same field of psychotherapy. Admittedly the long Freudian analysis was the counsel of perfection, but, short of that, much could be done by suggestion methods, perhaps aided by hypnosis, to create self-confidence, to resolve difficulties, and to give to the patient a clearer view of the situation at the conscious level. The lecturer parted company with Freud in the matter of religion. He agreed that in the deep analysis aiming at liberation of repressions it was necessary to be very careful in applying religious methods to the cure of mental conditions, because they might intensify the sense of guilt—by no means the same thing as guilt itself—and thus help to reinstate the repression. But of the value of religion in assisting the patient to a deeper philosophy of life and a more complete integration of the mind he had no doubt, and he deplored the fact that Freud, who had done so much to increase the freedom of the human spirit, should be such an uncompromising opponent of religion; for it was religion taken in its widest sense, that justified the established belief in ultimate freedom and spiritual destiny.

Explaining the analytic theory and method Dr. Brown said that in analysis the patient lay passive, usually out of the sight of the physician, who encouraged him to talk out for an hour at a time the things which came into his mind. In this way mental tendencies below the threshold of consciousness had an opportunity to show themselves. Ordinarily these were repressed by what Freud originally called the "censorship" and now the "super-ego." The process of analysis was misinterpreted if it was regarded as a dragging of the unconscious into the conscious. In fact the unconscious was always trying to become conscious, and was customarily held back by the activity of the super-ego; but it managed to assert itself, though in a disguised form, when the mind was weakened through general disease, mental shock, or sustained mental conflict. It also emerged, again usually disguised, in the dream state. The scientific psychological treatment was to relieve these repressions, encouraging the tendencies out into the open under the special conditions of analysis, where they could be dealt with by the rational mind, and their energies sublimated for higher social and cultural ends.

The psycho-analyst had often to be for a time to his patient a mother-substitute or father-substitute, or both. This was where the analytical method became very exacting. There were transferred to the physician the early emotional tendencies of the patient. One of the differences, by the way, between Freud's

method and the method of Jung, which was only to a small extent of a psycho-analytic nature, was that Jung held that transference should not occur. But no one could use the Freudian method without being intensely impressed by the fact of transference. The physician must be careful not to be caught up into counter-transference, or to resent his patient's vagaries, and if he was to be free from complexes himself, and to hold up to his patient an undistorting mirror, he himself must be analysed. A careful self-analysis would serve to some extent, but it was essential that it should be preceded by analysis from someone else. After this the analyst could proceed along the lines of self-analysis, to a great extent through his dreams, the systematic study of which was the best way of working out a "psycho-analytic autobiography."

THE MEDICAL PRACTITIONER AS PATRIOT

Prof. Morelli, secretary of the Fascist Syndicate of Doctors, has sent to all members of the Italian medical profession a circular which starts by saying that, in the circumstances of the moment, all doctors must consider themselves mobilised. It points out the opportunities that fall to the doctor, who visits the houses of all classes, to give encouragement in the sacrifices and privations that are necessary if Italy is to be victorious in the economic war. Nothing should be bought from the opposing nations, and here it is especially to the women that appeal must be made. "When," writes Prof. Morelli, "called by their sufferings, we cross their bedrooms, full of powders, paints, soaps, and toilet preparations, all coming from abroad, we must cry to them that this is a crime against the country and against her soldiers."

An "auto-train of defence against air and chemical warfare" has been fitted out for the purpose of giving practical demonstrations of the means of resistance to air and chemical attack. It was due to leave Rome last month and to visit, as rapidly as possible, the whole of Italy.

"IT ALL DEPENDS . . ."

NOWADAYS, when more and more parents are taking a theoretical as well as a practical interest in education, especially of the very young, they tend to pool experience and seek help in study groups under expert guidance. To meet the need of such groups the Home and School Council of Great Britain has republished in book form¹ some articles originally printed in their official organ *Parents and Teachers*. The articles deal with such qualities as confidence, helpfulness, dependability, and thoroughness, which are treated not as moral virtues but rather as qualifications for citizenship. On the other side of the picture attributes like fear, cruelty, stubbornness, and jealousy are shown to be avoidable handicaps which greatly hamper a child's relationship with its fellows. An intermediate chapter on rewards and punishments discusses the—often mistaken—means by which adults try to encourage the desirable and avoid the undesirable elements in children. Dr. H. Crichton-Miller writes a foreword and other medical contributors include Dr. E. A. Bennett, Dr. Henry Wilson, Dr. E. A. Hamilton-Pearson, the late Dr. Ian Suttie, Dr. Emanuel Miller, and Dr. Grace Calver. Mr. G. W. Lyward, director of the Finchden Manor Clinic and School, Tenterden, expresses sympathy with the irritation felt by parents—and not confined to parents—at the refusal, or inability, of lecturers on psychology to answer specific questions based on personal problems. "It was so exasperating, my dear, I quite hoped that he would tell me what to do, and instead he asked me about myself and the other children." Too often, in short, the answer starts "It all depends. . . ." But, as Mr. Lyward points out, most lectures and all these articles are but different ways of expressing one

¹ *Advances in Understanding the Child*. Compiled by the Home and School Council of Great Britain, 29, Tavistock-square, London, W.C.1. 1935. Pp. 71. 1s.

or two simple things, and it is upon these simple things that "it all depends": notably that certain qualities are not natural to a child at a certain stage of development and that the time factor must never be forgotten. It is, for example, unlikely to be disputed that helpfulness is not natural to any small child, but it is not always realised that there may be ages at which it is not natural to be truthful, brave, polite, or grateful. To give respect to the child, that is, to give respite, to take time into account, is the lesson here set out; and in this small book will be found practical help in the interpretation of the child's attitude at various stages of its development.

NEITHER JEW NOR GENTILE

A CORRESPONDENT writes: "The sympathetic reference in your last issue to the plight of the Jewish doctor in Germany was in my mind when, opening at random the anthology 'For and Against Doctors' compiled by Dr. Robert Hutchison and Dr. G. M. Wauchope,¹ I came across the following apposite quotation: 'By his commission the physician is sent to the sick, and knowing in his calling neither Jew nor Gentile, bond or free, perhaps he alone rises superior to those differences which separate and make us dwell apart, too often oblivious to the common hopes and frailties which should bind us together as a race. In his professional relations, though divided by national lines, there remains the feeling that he belongs to a guild which owes no local allegiance, which has neither king nor country, but whose work is in the world.' This comes from William Osler's 'Counsels and Ideals' (London, 1921, second edition, p. 73). The feeling to which it gives expression is no less strong to-day."

ADDRESSES AND ORIGINAL ARTICLES

TRAUMATIC EPILEPSY *

By C. P. SYMONDS, M.D. Oxon., F.R.C.P. Lond.

PHYSICIAN FOR NERVOUS DISEASES, GUY'S HOSPITAL; PHYSICIAN
TO OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN-SQUARE,
LONDON

OUR knowledge of the causes of an epileptic explosion on the one hand, and of the pathology of cerebral injury on the other, is so small that a discussion of traumatic epilepsy is apt very soon to stray into the by-ways of speculation. There are, however, certain questions of practical importance which it should be possible to answer from the facts at our disposal. How long after the injury do the fits usually appear? What is the character of the traumatic attacks? Focal or generalised? Minor or major? What is their prognosis? Is there any means of preventing this complication of head injury or of removing it when present? What is the incidence of traumatic epilepsy among patients with head injury? Finally, if we look backwards into the earlier story of the patient with traumatic epilepsy can we discover any features that might have led us to suspect this development? The last two questions are of special importance in relation to problems of compensation. The aim of this paper is to answer these questions as well as may be in the light of our present knowledge and to suggest ways in which that knowledge might be enlarged.

PATHOLOGY

The pathology of head injuries in relation to the cerebral symptoms which they cause is still so little known that generalisations in this direction are to be approached with some diffidence. With this caution I would state that the causes of traumatic epilepsy are these:—

1. In penetrating injuries infection of the meninges and brain.
2. In a small number of cases in which the fits occur within a few hours or days of the injury, epidural, subdural, or subarachnoid hæmorrhage.
3. In the great majority of cases the cause is direct injury to the brain substance occurring at the moment of the injury with subsequent cicatricial change. The reaction of the neuroglia to traumatic necrosis has been shown by Del Rio Hortega and Penfield¹ to be of slow development but far-reaching in its effects. The large astrocytes which are drawn towards the centre of the lesion are attached by their processes to the small blood-vessels, and traction upon these results in a disturbance of the circulation, which in turn may be responsible for functional instability in the neighbouring nerve-cells.

THE LATENT INTERVAL

A distinction must be made here between early and late fits. The latter constitute much the larger group. The early attacks usually occur within the first few days; the late attacks seldom earlier than two or three months after the injury. Early attacks due to epidural or subdural hæmorrhage are associated with evidence of increasing intracranial pressure which is fatal unless relieved by operation. In other cases pressure symptoms are absent and the attacks cease. It is generally believed that in this group subarachnoid hæmorrhage rather than cerebral injury is the cause and that the later prognosis is good, but Wagstaffe² found that of

37 of his patients with gunshot wounds who developed late epilepsy 5 had had early attacks. It is to be remembered, however, that these were cases of penetrating injury. In the closed injuries of civil accident early attacks are rare.

In the case of late attacks the latent interval may be very long—up to 15 or 20 years. In Wagstaffe's series of war injuries published in 1928 the average latent period was two years and one month. The average, however, gives a false picture of the common length of the interval.

The point has been well brought out by Feinberg³ whose graph I reproduce.

From my own material, comprising the notes of 380 cases of head injury, I have selected those cases of traumatic epilepsy in which the injury occurred in civil life and was of the "closed" variety. Reference to my own cases will be limited to those within this group. There are 26 in whom I have an accurate record of the interval. In these the average latent period was 2 years and 9 months. In 17 cases it was between 3 months

and 18 months. In the remaining 9 cases the interval ranged from 2 to 16 years.

Latent period between injury and first fit. The horizontal figures represent the latent interval in months and years, the vertical figures the number of cases for each period (Feinberg).

CHARACTER OF THE FITS

Whatever the nature of the pathological process at work the character of the fit is determined by the situation of the lesion. It would seem, however, that injury of certain parts of the brain is more likely to be followed by epilepsy than others. Schou,⁴ Aldren Turner,⁵ and Wagstaffe all found a preponderance of epilepsy with parietal injuries. These and other observers are agreed that traumatic epilepsy is much more often of a generalised than a focal character. In Aldren Turner's series of 48 cases of gunshot wound there were 38 with generalised and 10 with focal attacks.

In 28 of my patients in whom full notes of the character of the attacks are available it was as follows:—

Generalised attacks	..	..	..	..	24 cases.
Generalised attacks with focal aura	..	..	..	..	2 "
Jacksonian attacks	..	..	..	..	2 "

Of the 24 cases with generalised attacks:

- 11 had minor attacks at first, major attacks later.
- 4 had minor attacks only.
- 9 had major attacks only.

From this small number of observations it would appear that in closed injuries, traumatic epilepsy in 55 per cent. of cases takes the form of generalised attacks and that the commonest variety is that in which minor attacks are followed by major.

In all the cases of this series the attacks were multiple and in only two instances was the duration

* An address given to the Sheffield Medico-Chirurgical Society on Nov. 7th.
5557

of the epileptic liability less than one year when the patient was last seen.

PROGNOSIS

All observers are agreed that the liability to the attacks once established tends to persist, that the fits become more frequent and more severe, and that their repetition is often accompanied by slight progressive dementia of the kind observed in idiopathic epilepsy. As a late complication of head injury, therefore, traumatic epilepsy is likely to be a cause of total disability both for the manual and the mental worker.

I believe, however, that if the minor attacks are recognised and taken into account, the prognosis is not so bad as might otherwise appear. During the first few months after a severe head injury many patients will complain of attacks of dizziness. In most instances this will appear on analysis to consist of a brief sensation of mental dimness and unsteadiness on rising from the stooping posture and is probably due to a derangement of the vasomotor system. In other instances the sensation is vertiginous and provoked by quick movement of head or eyes without change of bodily posture—the result probably of labyrinthine damage. But there are others in whom the sensation is much more nearly that of a minor epileptic attack—without apparent cause there is a momentary cessation of clear awareness with a tendency to fall. Such attacks, I believe, are not uncommon in the earlier months after head injury, and though in some cases they may develop into frank epileptic attacks, more often they do not, especially if they are adequately treated.

TREATMENT

The medical treatment of traumatic epilepsy differs in no wise from that of the idiopathic variety. I do not propose to discuss it in this paper. Preventive treatment will follow similar lines—that is to say, that after a head injury of a kind or degree which carries with it a particular risk of traumatic epilepsy, a daily dose of bromide or luminal should be continued for a period of two years after the accident.

The value of surgical treatment has received fresh attention during recent years owing to the work of Foerster and Penfield,⁶ who advocate excision of the cicatrix whenever this can be localised with reasonable certainty, either from the focal nature of the attacks, or from evidence obtained by injection of air into the ventricular system. The value of such treatment cannot be estimated until its later results have been observed in a large number of cases, but having regard to the generally bad prognosis of traumatic epilepsy the attempt at surgical relief seems justifiable whenever the situation of the epileptic focus is certain.

FREQUENCY OF EPILEPSY AFTER HEAD INJURY

Although the rate of incidence of traumatic epilepsy is of considerable medico-legal importance, the available statistics afford only a rough guide to the medical man confronted with this problem. The term head injury in the first place is all-embracing and includes cases of confusion and laceration of the scalp in which little or no cerebral injury may have occurred. The incidence of epilepsy after fractures of the skull again provides no very useful information, since severe injury to the brain may occur without fracture. An inquiry into the rate of incidence in patients with closed injuries who have been concussed would be of value, especially if the concussion had been severe enough to warrant admission to hospital. Such an inquiry would have

to cover a large number of patients, and absence of other causes for the attacks would need to be verified in the positive cases. Even this, however, would not cover the whole ground, for occasionally traumatic epilepsy may occur after an injury without concussion.

Most of the published figures up to the present are concerned with gunshot wounds of the head, which, being for the most part penetrating wounds with simultaneous involvement of bone, meninges, and brain, and with the factor of infection usually present also, are by no means comparable with the closed injuries of civil life. That the incidence of epilepsy after penetrating wounds is considerably greater than in closed injuries appears from the figures given for war wounds by observers who distinguished between the two. Thus Wagstaffe found the incidence in cases in which the dura had been penetrated 18 per cent., whereas it was 2 per cent. in all other cases. Villaret and Bailly⁷ in 500 cases reviewed ten to twelve years after the wound found 16 per cent. of epileptics among patients who had suffered penetration of the brain, 6 per cent. when only the outer table of the skull had been involved. The incidence in all patients with gunshot wounds of the head was fully reviewed by Billet and Lenormant⁸ in 1921. They noted considerable discrepancies between the reports of different observers, depending doubtless upon the type of case which provided each with his material. The surgeon tends to collect patients with severe, penetrating injuries, the neurologist sees the less severe cases. Sargent⁹ computed the incidence in 18,000 British patients at 4.5 per cent., but this figure almost certainly errs on the low side. The computation was made only two years after the cessation of the war, and many patients developed epilepsy after this time. Moreover, the diagnosis rested upon the verdict of medical boards who at that time were possibly unaware of the significance of minor attacks in the early stages. This possibility also appears in Wagstaffe's paper. Writing in 1928 he found the incidence of epilepsy 10 per cent. in 377 cases, but in addition there were 28 patients who had complained of attacks which up to that time had not been approved as epileptic by the Ministry of Pensions.

The most reliable of the statistics quoted by Billet and Lenormant are probably those of Marie and Béhague who found 12.1 per cent. of epileptics among 3623 cases and Tuffier and Guillaud 10.41 per cent. in 6664. Both these computations however were made within three years of the end of the war, so that for the reason given above they may be regarded as underestimates. The total incidence of epilepsy after gunshot wounds of the head was probably in the neighbourhood of 15 per cent., and this figure may serve as a guide to its incidence in civil injuries of comparable nature and severity.

In 221 cases of civil head injury of all kinds Bran¹⁰ found the incidence of epilepsy 8 per cent. Schou in 200 cases of head injury reported to a Danish insurance company found it 4.5 per cent. Feinberg, in his valuable paper dealing with all head injuries of whatever kind reported to a Swiss insurance company between the years 1919 and 1933, found 50 instances of traumatic epilepsy in 47,130 cases—roughly one case in a thousand. In 7 cases the fits were early—that is, within eight days of the injury. In the late cases the interval varied from one month to 15 years. Feinberg's figures are of great interest and provide what is probably a fair estimate of the incidence of traumatic epilepsy in all head injuries.

INCIDENCE OF LATE EPILEPSY IN RELATION TO
EARLIER SYMPTOMS

In what types of case does the risk of late epilepsy appear greatest?

Fractured skull.—Feinberg's analysis of the Sural statistics shows, as might be expected, that in civil accidents fracture of the skull is relatively infrequent, and that traumatic epilepsy may occur in cases without fracture. But it appears that the incidence of epilepsy is considerably higher in the group of cases with fracture of the skull. Among 3906 cases with fracture late epilepsy occurred in 19—that is, in 5 per 1000—whilst in 16,762 cases of concussion without fracture it occurred in 24, or 1.25 per 1000. Of the 19 cases with fracture 12 were fractures of the vault, 7 fractures of the base.

Brun's series of 470 fractures yielded 3 cases of epilepsy—all with fractures of the vault.

In my own series among 27 cases of traumatic epilepsy, in which the presence or absence of a fracture was determined, fracture was present in 17, absent in 10. We may conclude, therefore, that the presence of a fracture, and especially a fracture of the vault, is a point to be taken as in favour of epilepsy as a sequel.

Duration of unconsciousness.—In 24 of my own cases of closed injury in which the period of unconsciousness was accurately recorded the average duration was 9½ days. The shortest period was 1 hour, the longest 28 days.

In 6 cases (25 per cent.) it was under 24 hours.
.. 17 .. (70.8 ..) .. 4 days or more.
.. 12 .. (50 ..) .. 10 ..

If these figures are representative, it is clear that a prolonged duration of unconsciousness after the injury carries with it an increased risk of traumatic epilepsy, for in the closed injuries as a whole a duration of more than four days' unconsciousness is by no means common. On the other hand, a brief period of unconsciousness does not exclude the possibility of traumatic epilepsy. The fact is well illustrated by the following case.

A cadet, aged 18, fell from his horse in a riding-school and was dragged, his head being bumped against the wall. He got up and remounted, and subsequently ate his midday meal with his fellows. He was observed to be acting stupidly and was taken to hospital where he came to his senses six hours after the injury without any knowledge of what had happened to him. He was kept in hospital a week and afterwards had a week-end away before returning to duty. He had no headache or other immediate sequelæ. Two years later he had his first epileptic attack, waking one morning to find he had bitten his tongue. In the subsequent year he had six more attacks. This patient showed no abnormal physical signs, but the X ray revealed a linear fracture of the left frontal bone running from a point 2 inches above the supra-orbital margin upwards and backwards to end an inch from the frontoparietal suture. The family history in this case provided no evidence of inherited neuropathy.

Early fits.—Wagstaffe's observations have already been referred to in this connexion. Although it is probably true that the early fits frequently do not recur, their occurrence indicates an increased risk of late epilepsy.

Signs of focal damage.—If there is evidence in the early stages of local cerebral injury—such as hemiparesis, sensory defect, hemianopia, or dysphasia—there is theoretical ground for the belief that a scar will develop which may prove an epileptic focus. Of 25 of my own cases with adequate notes upon this point, there was evidence of focal damage in 9. As many of the patients were seen some months or

years after the injury, without medical notes of the early symptoms, the actual incidence may have been higher. In 4 cases the focal symptom was dysphasia; in the other 5 there was unilateral weakness of one or both limbs, with appropriate reflex changes.

Traumatic dementia.—Memory defect and deterioration of character and personality persisting long after the patient has emerged from the state of traumatic stupor, probably indicate diffuse organic cerebral damage and might equally be expected to show an association with traumatic epilepsy. Of the 25 cases already referred to 6 showed symptoms of this order.

Continued liability to headache.—We know very little of the causes of traumatic headache but it presumably depends upon organic damage, and when an unusually persistent liability to headache remains the inference must be that this damage has been unusually severe. In 9 of the 25 cases referred to the liability to headache had persisted for one year after the injury, or until the occurrence of the first attack. In this group of 25 patients 6 had neither focal symptoms, dementia, nor persistent headache, but of these, one had a depressed fracture of the right frontal bone and a generalised convulsion half an hour after the attack; another had a fracture of the vault and was unconscious for four or five days; another was the case already described of the cadet with a linear fracture of the vault. In only 3 cases therefore was there a complete absence of any of the symptoms which we have discussed as having a possible bearing on the risk of late traumatic epilepsy.

TRAUMATIC OR IDIOPATHIC?

There is one further question to be asked. What are to be the diagnostic criteria for traumatic epilepsy? The character and course of traumatic epilepsy may exactly resemble those of idiopathic epilepsy. Idiopathic epilepsy may begin in adult life and may occur without any family history of the malady. This is true only of a small proportion of the total number of idiopathic epileptics, but idiopathic epilepsy is a common disease. Head injuries are also common. We must therefore allow for coincidence.

A story of head injury will be presented to us by a considerable number of adults with recent epilepsy. Are we going to accept the very fact of past injury to the head as evidence of a traumatic cause for the epilepsy, provided that no other cause can be found and the family history is negative? The answer I think must be "No." The history must be that of an adequate head injury to warrant the diagnosis of traumatic epilepsy. But what is an adequate head injury? Most writers on the subject have evaded this difficult question. Feinberg, however, has gone into it fully. Among his 47,130 cases of head injury he found 100 epileptics, but in 50 of these he found the traumatic origin unproven, on the ground either that there was an epileptic inheritance, that there were other possible causes, for instance alcoholism, or that the injury had been inadequate. He lays stress on the importance especially of "bridge symptoms"—that is, symptoms such as headache, insomnia, difficulty in concentration, and giddiness persisting for months after the injury though not necessarily up to the time of the first fit. He also, and I think rightly, gives weight to a finding of blood in the cerebro-spinal fluid shortly after the injury as indicating a strong probability of cortical laceration.

In selecting my own material I have been guided by the features which with experience I have begun to expect in the past history of traumatic epilepsy.

Herein, of course, lies a fallacy. If we accept only as traumatic epileptics those patients whose original trauma has been of a certain severity, we are arguing in a circle if we say that it is patients with just this kind of injury who are likely to develop epilepsy. I can see no way at present out of the difficulty, but the general principle for guidance in a particular case must I think be this. Is there any evidence from the story of this patient's head injury which suggests that he may have sustained an injury to the cortex? If the answer is "Yes," then it is fair to assume that the epilepsy is traumatic.

There is one more aspect of this subject which deserves mention. Of the traumatic epileptics in my own series whose cases involved compensation, 75 per cent. had accepted final settlements before the first fit occurred. Most of them had recovered from the first effects of the accident and had returned to work and had been content to accept a small lump sum. Subsequently they were disabled without hope of further recompense. In any case of adequate head injury the risk of traumatic epilepsy must be remembered and allowed for. Under the Workmen's Compensation Act there is an excellent provision whereby the injured person may accept a lump sum settlement on condition that if a specified complication should arise later the question of compensation may be reopened. This provision should, in my opinion, be utilised against the risk of traumatic epilepsy much more often than it is at present. In the case of accidents to which this Act does not apply—for instance, motor accidents, of which there are now a great many—there is no such loophole, and the computation of the risk and its value in the individual case is a matter of the greatest difficulty. We need for guidance a great deal more information along the lines which I have attempted to suggest in this paper, and I hope that as the result of collective effort it may be forthcoming.

SUMMARY

1. Fits occurring within the first few days after the injury (early fits) are probably in most cases due to epidural, subdural, or subarachnoid hæmorrhage. They are relatively uncommon and do not as a rule lead to the development of late epilepsy.

2. The late fits, with which this paper is chiefly concerned, result from injury to the cerebral substance at the moment of injury with the subsequent formation of a neuroglial scar.

3. In these cases the interval between the injury and the first fit varies from a few months to many years. The commonest time of occurrence is at the end of the first year and, in the majority of cases, the interval is less than 18 months.

4. The character of traumatic epilepsy is more often generalised than focal. The attacks may be of minor or major degree. The former often precede the latter.

5. The prognosis of traumatic epilepsy is much the same as that of the idiopathic variety.

6. Medical treatment is the same as that of idiopathic epilepsy and should include preventive treatment. Surgical treatment is discussed.

7. The incidence of epilepsy after gunshot wounds of the head is from 12–15 per cent. Civil injuries are for the most part closed injuries, and the incidence of epilepsy in such cases is much lower. The estimates of different authors vary from 8 per cent. to 1 per 1000, according to the type of case reviewed.

8. The incidence of late traumatic epilepsy, with special reference to the closed injuries of civil accidents,

is discussed in relation to fracture of the skull; a long duration of unconsciousness; the occurrence of early fits; signs of focal damage; traumatic dementia; and persistent headache. One or more of these features is usually present in the earlier story of the patient with traumatic epilepsy.

TREATMENT OF HÆMATEMESIS AND MELÆNA WITH FOOD

THE MORTALITY

By PROF. E. MEULENGRACHT, M.D.

CHIEF PHYSICIAN, BISPEBJERG HOSPITAL, COPENHAGEN

AT the Sixteenth Scandinavian Congress for Internal Medicine, held at Uppsala in 1933, I reported results I had obtained in treating hæmatemesis and melæna by giving the patients *something to eat*—i.e., varied food from the very first day, and plenty of it.

The reasons which induced me to change the treatment hitherto given—namely, fasting followed by very cautious feeding—were: (1) that exhausted patients often died after hæmorrhage, in spite of scrupulous dieting; (2) that sometimes patients with protracted hæmorrhage stopped bleeding when they were given food; and (3) that very often ambulant patients recovered from severe melæna without making any particular change in their ordinary diet. Furthermore, it seemed to me of questionable advantage to starve a patient at a time when he is presumably in special need of support. I had my doubts whether it was really desirable that the stomach should be empty of food and contain free acid gastric juice, and I thought it improbable that a diet insufficient in calories and vitamins was ideal as a means of promoting healing of ulcers.

It was on these grounds that I decided in 1931 to alter my treatment and give these patients something to eat. By 1934, when my first report appeared in the *Acta Medica Scandinavica*, I had treated 119 cases of hæmatemesis and melæna according to the new plan, and had formed the opinion that the mortality from profuse ulcer hæmorrhage was much reduced, that the general condition and the condition of the blood improved much more quickly, and that convalescence was shorter. By September of this year the total number of cases treated was 251, and they form the basis of this paper.

THE TREATMENT DESCRIBED

From the day after their admission to the hospital all the patients are given a full purée diet, together with a mixture consisting of sod. bicarb. and mag. subcarb. (ää 15.0 grammes), and extract hyoseyam. 2.0 g.; one teaspoonful three times daily; also

0.5 g. ferri lactas t.d.s. The purée diet includes the following meals:

- 6 A.M.: Tea, white bread and butter.
- 9 A.M.: Oatmeal with milk, white bread and butter.
- 1 P.M.: Dinner.
- 3 P.M.: Cocoa.
- 6 P.M.: White bread and butter, sliced meats, cheese, and tea.

The dinner includes a variety of dishes—e.g., meat balls, timbale, broiled chops, omelette, fish balls, vegetable gratin, meat gratin, fish gratin, mashed potatoes, vegetable purées, vegetable soups, cream of vegetables, stewed apricots, apple sauce, gruel, and rice and tapioca puddings. The patients are allowed to have as much as they want. In a few cases (12) in which large quantities of blood have been lost they have been given one or two blood transfusions soon after admission.

RESULTS

The entire series comprises 286 cases of severe hæmatemesis and melæna. Omitting 19 cases of cancer in the digestive tract, chiefly the stomach (in 3 of which death followed the hæmorrhage) and 16 cases of œsophageal varices due to cirrhosis of the liver (3 of which were immediately fatal), there remain 251 cases of hæmatemesis and melæna, which have been taken to be genuine ulcer hæmorrhages—i.e., arising from ulcers of the stomach and duodenum. Among these 251 patients there were 3 deaths after the hæmorrhage. In chronological order the cases were as follows:—

CASE 1.—Male, aged 45. Admitted August 22nd, 1931. Had had symptoms of ulcer for six years and had received medical treatment three times at various hospitals. Four years previously had had a posterior gastro-enterostomy. For some years the patient had also had symptoms of heart disease, and for that reason had been awarded an invalidity pension. A week before admission he had dyspeptic symptoms and vomiting, and melæna began on the day before he came into hospital. There was a hæmatemesis shortly after admission, the patient was profoundly anæmic, with hæmoglobin 32 per cent. He was put on the purée diet with pulv. alcalin. c. hyosc. one teaspoonful, and ferri. lact. 0.5 g. t.d.s. After six days in hospital he became suddenly worse with abdominal pain but no rigidity. A transfusion was given without improvement; the temperature rose and he died same day. Autopsy showed: diffuse peritonitis following perforation of a jejunal ulcer; chronic gastric ulcer; aortic stenosis with enlargement of the heart and chronic interstitial nephritis.

CASE 2.—Male, aged 40. Admitted July 4th, 1933. Had previously been treated eight times in various hospitals for chronic nephritis and heart disease; and twice in the previous year for melæna. For eight days before admission he had had black stools, and there had been a hæmatemesis on the previous evening. While in hospital he had melæna, and was in a state of suburæmia. Hæmoglobin, 48 per cent.; blood-urea, 78 mg. per 100 c.cm. Electrocardiography showed signs of myocardial degeneration. He was given the same treatment as Case 1, and his condition improved considerably. Seventeen days after admission, however, he collapsed and died suddenly. The autopsy revealed a duodenal ulcer, with hæmorrhage into the stomach from an eroded artery; cardiac hypertrophy and myocardial degeneration; and chronic nephritis.

CASE 3.—Female, aged 76. Admitted Nov. 17th, 1934. Dyspeptic symptoms for about a year. Hæmatemesis the day before admission. Very poorly on admission. During the day five stools with blood. Died within 24 hours without any treatment. Autopsy showed: gastric ulcer and hæmorrhage into the stomach, advanced arterio-sclerosis, and myocardial degeneration.

Of these three fatal cases the first ought, strictly speaking, to be omitted, for the patient did not die of

hæmorrhage but of perforation with diffuse peritonitis. The second patient died 17 days after the commencement of the treatment from profuse hæmorrhage from an eroded artery. The third died shortly after admission without having got as far as the "treatment with food." If this third case is included we get a mortality percentage of about 1½; but without this patient (for she had not been under the new treatment at all) the mortality is about 1 per cent.

DISCUSSION

I shall now compare this mortality with that for severe ulcer hæmorrhage treated on the usual lines—i.e., by complete or partial starvation followed by an ulcer diet.

Even the mass of statistics available show considerable variations. In England, for instance, the mortality is given by Hurst (1924) as about 4 per cent.; by Bulmer (1932) as 10.7 per cent.; by Chiesman (1932) as 25 per cent.; by Aitken (1934) as about 11 per cent.; by Hellier as 13 per cent., 12.5 per cent., and 8.3 per cent. for proved, probable, or doubtful ulcers respectively; by Lethby Tidy as 19 per cent.; by Davies and Nevins as 21.5 per cent.; and by Burger and Hartfall as 22.6 per cent. (hæmatemesis only!), which figure should be compared with Hurst's earlier 4 per cent., also at Guy's Hospital. These are all large collective statistics of hospitals covering a period of years.

At the Royal Society of Medicine discussion on hæmatemesis in March, 1934, the figures presented were even more variable. As Bennett points out, the differences from place to place may possibly be explained by the differences in the materials. From Canada Lynch (1927) gives a mortality of 12.9 per cent., and from New York Hinton (1931) 20 per cent. The extensive Scandinavian statistics show: from Sweden Mattisson (1931) 7 per cent., and Mossberg (1933) 9 per cent.; from Norway Frostad (1934) 9.4 per cent.; and from Denmark Lindberg (1914) 7.3 per cent., and Christiansen (1934) 7.9 per cent.

As no doubt there are national and local differences in the materials I must for comparison use a series that is uniform with mine. Christiansen's fulfils this condition, his patients being treated at the Kommunehospital Department 2, Copenhagen, where the type of case admitted is identical with mine. Like my own series Christiansen's has been reduced by omission of cancerous and varicose hæmorrhages, the only difference between the two is that the cases at the Kommunehospital were treated in the orthodox way.

For the ten years 1923–32 Christiansen had a hæmorrhage mortality of 7.9 per cent. in 289 patients—a figure which corresponds very closely with what we had in my department under the old treatment. The difference between Christiansen's mortality of 7.9 per cent. and mine of 1 per cent. is surely very striking. We have had four years' experience with 251 cases, and it seems to me justifiable to assume that the new "treatment with food" is a means of radical improvement. The mortality of 1 per cent. in the series thus treated is, I fancy, the lowest in any large series on record.

That the hæmorrhage is not aggravated putting an abundance of food in the stomach must apparently be taken as a fact; the cause may be that the empty stomach, as we know, moves more than the full one. Possibly in most cases the bleeding has already stopped before the patient comes into hospital. I am inclined to think so. At any rate it must certainly not be supposed that blood in the faeces implies that the lesion is still bleeding. With our former treatment it was on the average 13.4 days, with 4.5 defæcations, before the faeces became free of blood (Gregersen's benzidine test); with our present

treatment melæna lasts on the average 10.2 days with 4.8 defæcations (first report, 1934). This, however, does not mean that the lesion bleeds so long; it is merely that evacuation of the blood by the bowels is a long process. This interpretation is supported by Hesser's investigations showing that on the average 8-21 days elapse before ingested barium salts are completely discharged by patients with bleeding ulcers.

I believe, however, that this radical change in mortality brought about by "treatment with food," is due to something beyond its effect on the hæmorrhage itself. For my experience is that patients with hæmatemesis and melæna do not usually die until some time—on an average 8 days—after the hæmorrhage begins. Thus in my opinion they do not die directly from loss of blood, but rather from general exhaustion, often with complications. This exhaustion is no doubt primarily the result of their anæmic condition, but it is accentuated by extreme insufficiency in food and drink, with which they are ordinarily supplied at this critical moment. To me this is the explanation why, with "treatment with food," we get a mortality so much lower, for, instead of weakening the patient still more, we are giving him support when he badly needs it.

To my mind the decrease in mortality is the strongest argument for the new treatment, but there are other advantages. In the first place the patients make a much more rapid recovery from the state of shock which follows the loss of blood. They escape the broken ice, the water, the cold tea, the stingy doses of gruel, the milk, and the other trials of traditional practice, and they regain their strength much more quickly. Their blood also regenerates more rapidly—an improvement which I attribute chiefly to the mixed diet, and only secondarily to the iron given. Their dyspeptic symptoms are apt to disappear with surprising speed, and with few exceptions they have had no subjective symptoms on discharge. The advantages both to physicians and nurses are obvious, for the patients are easier to handle and naturally more contented with their lot. At the Bispebjerg Hospital we allowed them to move freely in bed, and to get up after two or three weeks. The average period before discharge has been five weeks, by which time convalescence is usually at an end. Before discharge they are given Ewald's test-meal and Kemp's test-meal, and the stomach is radiographed. They are then advised to continue with the medicine for another six weeks and with the purée diet for 4-6 months.

It may be asked why these patients with ulcers should not have a chance of getting the regular ulcer cure; in other words (as someone has put it), why should a patient with hæmatemesis be penalised by refusing him the ulcer cure? My answer is that I am not at all sure that the regular ulcer cure, with its partial starvation and extreme monotony, is really very sound. And even if it is desirable in ordinary cases I question whether it is applicable to patients who have lost blood and are in no fit state for debilitating dietetic measures.

Another question which will certainly be asked is: What about the duration of the results; does the ulcer heal permanently? On the basis of the present report I am unable to supply an answer. How far the chances of permanent cure are improved or otherwise by substituting a purée diet, or some other form of "well-balanced diet" in non-irritating and easily digestible form for the ordinary ulcer cure cannot at present be judged. With our present knowledge of vitamins, and the principles of nutrition in which

on the whole we now put our faith, it seems justifiable to assume that the healing processes are *not* favoured by an insufficient diet. I must, however, leave this problem for further study. My main thesis now is simply that whatever treatment is chosen, it should not be made more drastic for patients with hæmorrhage than for those who have none. On the contrary, it should be made less rigorous.

RADIOLOGICAL ASPECTS OF ANOMALIES OF INTESTINAL ROTATION

By E. L. RUBIN, M.D. Liverp., D.M.R.E.

RADIOLOGICAL REGISTRAR, LIVERPOOL ROYAL INFIRMARY

ALTHOUGH minor degrees of developmental misplacement of the intestine are quite commonly met with, failure of the second stage of rotation of the midgut loop is comparatively rare. It has been discovered from time to time post mortem and is occasionally encountered by the surgeon operating either for an unallied condition or for one of the acute abdominal emergencies to which anomalies of intestinal rotation may give rise. Where non-rotation of the gut has been discovered at operation, its existence has usually been unsuspected beforehand, and this is not surprising since, apart from an isolated and apparently neglected case reported by Mayo¹ in 1912, the condition was not observed radiologically until 1921, when two cases of "left-sided colon" were published by Hurst.² There is now however a fuller appreciation of the surgical importance of anomalies of intestinal rotation and they are no longer regarded as mere anatomical curiosities. Spitz³ has reported 3 cases of common mesentery with non-rotation of the intestine, to add to the 41 such cases in which the X ray findings have been described.

No attempt is made here to discuss the embryology of intestinal rotation: a detailed and widely accepted account of the factors concerned is given by Frazer and Robbins⁴ and both embryological and surgical aspects are fully considered by Dott.⁵

It will be remembered that it is in the midgut loop that errors of development are commonest—i.e., in that portion of the alimentary tract from the duodenal biliary papilla to the left third of the transverse colon, or that portion of the intestine which receives its blood-supply from the superior mesenteric artery. Of the three stages of rotation, the first stage takes place between the fifth and tenth weeks while the loop lies in the umbilical cord, and lasts to the time of return of the intestine to the abdomen. Failure of the first stage of rotation occurs only in connexion with the rare condition of extroversion of the cloaca, and the term non-rotation refers to a failure

in the second stage. The second stage is the stage of return and rotation; occurs about the tenth week, and comes to an end when the whole length of the colon is in its proper plane relative to the small intestine. The cæcum, which at first lies on the left side of the body cavity in the umbilical region, rotates round the axis of the superior mesenteric artery so that it comes to lie on the right side in the subhepatic region, the cæcum and proximal colon sharing a mesentery common to them and to the small intestine. The third stage is concerned with the descent of the cæcum and its fixation to the posterior abdominal wall by a fusion of its mesentery with the posterior parietal peritoneum. In this stage also, the duodenojejunal flexure is formed and fixed.

In most of the recorded cases non-rotation or mal-rotation of the intestine has given rise to no symptoms and has been discovered accidentally at operation (Malcolm,⁶ Rixford,⁷ Eggers,⁸ Klopp,⁹ Schrup,¹⁰ Corkhill,¹¹ and others). Of the 48 cases including 3 collected by Dott, 35 were accidentally discovered and the intestinal misplacement gave rise to no symptoms. In 13 cases erroneous fixation of the bowels was the directly predisposing cause of intestinal obstruction (Denzer,¹² Lee and Nye,¹³ Moritz,¹⁴ Kelley,¹⁵ and others). The immediately exciting cause is commonly a torsion or volvulus of a large segment of intestine. The surgical aspect of derangement of intestinal distribution is discussed by Green,¹⁶ and a comprehensive review of published cases is made by Haymond and Dragstedt.¹⁷

It is clear that the surgeon, in attempting to reduce a segment of bowel which has undergone torsion, will be unable to visualise the condition of the intestine before torsion if he fails to recognise the coexistence of an anomaly of rotation. As Dott points out, such failure may lead to grave errors in procedure or to injurious prolongation of the operation, or to its abandonment. The difficulty is well illustrated by a case reported by Mole¹⁸ and it has

also been remarked by Grant.¹⁹ Naturally it is impracticable to carry out full X ray examination of patients requiring immediate operation; but since the symptoms to which anomalies of rotation may give rise have often been experienced intermittently since early childhood, a large proportion of cases will come under observation before

FIG. 2 (Case 1).—Left-sided colon by barium enema.

complete obstruction has occurred; and the value of a preoperative knowledge of the X ray appearances in developmental intestinal misplacements is manifest.

CASES OF NON-ROTATION OF GUT

CASE 1.—Healthy male, aged 44. Admitted to hospital for operation for right inguinal hernia which had been present for 4½ years. His only symptom was occasional colicky pains in lower abdomen (six months). Hernia

well controlled by truss. The colicky pains were experienced only when the truss was not being worn and never when the patient was lying down. No other complaint. Stated he had an ulcer on the stomach when he was seven years of age, but no tangible information on

FIG. 1 (Case 1).—There is a small duodenal diverticulum and inversion of the duodenum. The duodenojejunal junction is situated in the right hypochondrium.

this point could be obtained. In view of his colicky pains (which were thought to be due to the hernia when decontrolled) the patient was referred for X ray examination of the gastro-intestinal tract. The findings are as follows:—

The opaque meal passed normally along the œsophagus into the stomach which was normally placed, presented no unusual feature, and emptied at a normal rate. There was a small diverticulum about the junction of the first and second parts of the duodenum (entirely unassociated with symptoms). The first and second parts of the duodenum took a normal course, the second part passing vertically downward a little to the right of the midline to form the lower curve at its junction with the ascending or third part of the duodenum. The direction of the lower flexure was reversed so that the third part of the duodenum was directed from below upwards and to the right. There was no duodenojejunal flexure and the junction of the duodenum and jejunum was situated in the right hypochondrium (Fig. 1). On following the course of the meal through the gastro-intestinal tract it was found that the whole of the small intestine, with the exception of a small segment of the terminal ileum, lay on the right side of the abdomen. The rate of passage of the meal through the small bowel was rather rapid, and in three hours the head of the meal had filled the proximal three-fourths of the ascending colon. A film taken at this time showed the cæcum and greater part of the ascending colon situated entirely on the left side of the abdomen. The terminal ileum entered the cæcum from right to left. Six hours after the administration of the meal saw the barium entirely in the ascending and transverse colon except for a trace in the terminal ileum. The ascending colon rose rather high and terminated in a flexure in relation to the greater curvature of the stomach. After 24 hours, the barium had been partly evacuated. The remainder was mainly distributed throughout the descending and transverse colon.

A barium enema (Fig. 2), which passed normally, confirmed the left-sided location of the entire colon. There was no great redundancy. With the patient supine, the shadows of the ascending and descending colon were very largely superimposed. The splenic flexure was normally situated and the transverse colon was represented by a short downward loop. There was some mobility of the ascending colon but this did not appear to be excessive.

On fluoroscopic examination of the thorax, the heart and great vessels were normally placed. The liver dullness was normal and the patient presented no evidence of any other developmental abnormality. The above conditions were symptomless and their discovery

FIG. 3 (Case 2).—Right-sided inversion of the duodenum. The duodenojejunal flexure is absent from behind the stomach.

accidental, so that the question of operation did not arise (except that the inguinal hernia for which the patient was admitted was repaired, the sac presenting no unusual feature). But the X ray appearances are those of failure of the second stage of rotation of the midgut loop and are in themselves conclusive.

The condition seen in this case is variously described as non-rotation, "left-sided colon" and mesenterium commune. The whole of the midgut shares a common mesentery so that, unless the ascending colon forms secondary attachments, the small intestine, ascending colon, and proximal half of the transverse colon may be freely suspended in their common mesentery by a narrow pedicle, thus forming ideal conditions for torsion or volvulus formation. Vasselle,²⁰ in describing the X ray appearances in non-rotation, remarks on the rapid rate of passage of the barium meal through the intestine, a feature which other observers have also noted. Babaianz and Kadrnka²¹ report 3 cases of non-rotation, and give the following six characteristic features in the X ray appearances the presence of which, they say, would justify the diagnosis of "common mesentery": (1) right-sided inversion of the third part of the duodenum; (2) absence of the duodenojejunal flexure; (3) position of the small intestine on the right side; (4) position of the proximal colon on the left side; (5) absence of the hepatic flexure; and (6) the formation of another proximal colic angle (which they term the "mesenteric.") Each of these features is illustrated in the case described above.

CASE 2.—Essentially similar to Case 1, and will be summarily described: Male aged 45; gastropptosis; ulcer on lesser curvature and small six-hour residue in stomach. The third or ascending part of the duodenum ran from below upwards and to the right and the duodeno-

jejunal flexure was absent from behind the stomach (Fig. 3). The small intestine was situated almost entirely on the right side and the large intestine wholly on the left side of the abdomen. Apart from the misplacements, the appearances of and the rate of passage of the barium through the bowel were normal. The intrathoracic vascular shadows were normally placed. The appearance of the colon by barium enema is illustrated in Fig. 4.

A further case of non-rotation of the gut in a male aged 44 was seen by Dr. R. E. Roberts as long ago as 1920 and has hitherto been unpublished. I have been privileged to see the original films of this case, which clearly show sinistocolon and right-sided inversion of the duodenum as in the other cases here described.

When symptoms are present with congenital malformations of the mesentery they are usually complained of in childhood. Waugh²² records 5 cases in children, 4 of whom had been under continuous treatment for "indigestion" from within the first few months of life. Attacks of abdominal pain of great intensity were experienced intermittently over a period of years, each attack of pain subsiding and leaving no trace of detectable organic change in any of the abdominal organs or their functions. The symptoms were unlike any of the well-known surgical lesions, but 3 of the cases were labelled "chronic appendicitis." The most arresting physical sign is a sense of emptiness in the right iliac fossa. This fossa is normally occupied by ascending colon and small intestine, both being components of the midgut. Either the one or the other may be absent and an asymmetrical fullness may be noted on palpating the left iliac fossa. The symptoms and signs present in childhood may then be suggestive of the condition giving rise to them, and a preoperative clinical diagnosis is not infrequently made.

Waugh describes such a case diagnosed on symptoms and physical signs in which the left-sided location of the colon was confirmed at operation. He accidentally discovered an exactly similar case of non-rotation in a second child during an operation for acute appendicitis, apart from the symptoms of which the patient never had a complaint. In both cases the condition was one of non-rotation, but in the first case (associated with symptoms) the ascending colon was enclosed in the same primitive layer of mesentery as the small intestine. No secondary fixation had occurred anywhere, so that the whole weight of the primitive midgut was supported by the stomach. In the second case (unassociated with symptoms) the ascending colon had acquired over

FIG. 4 (Case 2).—Barium enema. The colon is situated entirely to the left of the midline and the shadows of the ascending and descending colon are largely superimposed.

with symptoms) the ascending colon was enclosed in the same primitive layer of mesentery as the small intestine. No secondary fixation had occurred anywhere, so that the whole weight of the primitive midgut was supported by the stomach. In the second case (unassociated with symptoms) the ascending colon had acquired over

its whole length a secondary attachment and firm fixation to the left side of the bodies of the vertebrae and was not contained within the fold of primitive mesentery common to it and the small intestine. The absence of fixation of the ascending colon appears to be a deciding factor as to the presence of symptoms. Symptoms when present are clearly not due to the misplacements per se, but to the results of the excessive mobility or undue fixation of the bowel which may accompany them, such conditions coming outside the pale of the "normal fluidity of the abdominal anatomy" which has been convincingly demonstrated by Barclay.²³

In the adult symptoms are less often encountered. They have been described in some detail by Spitz,³ and when present are usually vague. The commonest complication in adults is volvulus of the ileocaecal segment.

OTHER ANOMALIES

Minor degrees of defective mesenteric fixation at the third stage of rotation are frequently encountered, and the undescended caecum is fully considered by Peirce.²⁴ Left-sided caecum, of course, is not very

rare and lesser degrees of "wandering caecum" are a commonplace. But they are not without significance, as Waugh²⁵ has shown in his well-known work on the morbid consequences of a mobile ascending colon. For this reason they are briefly considered here. Fig. 5 is a diagram of the colon of a male

FIG. 5.—Left-sided caecum.

aged 56. The caecum was situated in the left iliac fossa from which the ascending colon rose diagonally across the abdomen to reach a normally placed hepatic flexure. The caecum retained its position on the left side of the abdomen when the patient lay on his right side and was observed there on several different occasions.

The question whether a left-sided caecum is due to malrotation (second stage) or whether it is due to defective mesenteric fixation (third stage) may arise. It has been asserted that adhesions found round a left-sided caecum may be prenatal in origin, occurring as a result of a supposed fetal peritonitis. The presence of such adhesions has been offered as an explanation of the failure of the colon to rotate—an explanation which is rejected by Dott.⁵ At any rate the differentiation between non-rotation and "excessive rotation" may be made, according to Dott, by observing the location of the appendix (or the point of entry of the terminal ileum into the caecum). If a left-sided caecum is associated with non-rotation, the root of the appendix will be found on the right side of the caecum. If a mobile caecum has crossed the floor of the pelvis to the left side, the root of the appendix will be found on its left surface. Although these points may be easily recognised when the caecum is seen at operation, there will often be difficulty when one is dealing with shadows in the region of a bound-down caecum, and the differentiation is best made radiologically by noting the presence or absence of other anomalies in the duodenum and small intestine. Spitz³ illustrates a case radio-

graphically and Denzer¹² describes one post mortem, in which the disposition of the colon was, in each case, similar to that illustrated in Fig. 5 (caecum in left iliac fossa, hepatic flexure on right side). In both cases the third part of the duodenum ran an abnormal course and the small intestine was situated on the right side of the abdomen, both cases being examples of mal-rotation. In the case illustrated in Fig. 5 the duodenum ran a normal course throughout its length, and no abnormality other than the left-sided position of the caecum was to be found. The case is therefore, in all probability, one of "excessive rotation." It may be said that if, in a case of left-sided caecum, the small intestine is situated on the right side of the abdomen and right-sided inversion of the duodenum is present, the case is undoubtedly one of non-rotation. If a left-sided caecum is unassociated with these anomalies the case is probably one of mobile caecum which has crossed the floor of the pelvis to the left side, and become fixed there, though the differentiation cannot be made with certainty on X ray evidence alone.

There are, of course, many intermediate and varied types of congenital anomalies of the mesentery which may give no radiological evidence of their presence. In the rare condition of reversed rotation, the abnormal relation of the transverse colon and duodenum to the superior mesenteric artery can be demonstrated only at operation, and since the large bowel occupies its normal position in the abdomen (except that its anterior and posterior surfaces are reversed) the condition is likely to pass unrecognised. Anomalous bands compressing the bowel may give indications of such compression, but, in the absence of any demonstrable anomaly of the duodenum, small bowel, or colon (which should always be sought, especially in children), no radiological indication of the cause of the compression. With regard to gross misplacements, an instructive case is described by LeWald. X ray examination was discontinued after an abnormality in the course of the duodenum had been noted; at operation the condition of non-rotation was found. LeWald²⁶ makes clear the importance, in recognising anomalies of rotation, of visualising the course of the duodenum throughout its length and of making a complete examination of the gastro-intestinal tract.

Where there are anomalies of distribution of the intestine other congenital abnormalities are seldom to be found. Much of the colon, together with other abdominal viscera, may be found in the pleural cavity owing to congenital openings in the diaphragm. A case of non-rotation is reported by Grant²⁷ in a patient who also had congenital absence of the left radius, thumb, first metacarpal and corresponding carpal bones. Non-rotation of the intestine could hardly be confused with transposition of the viscera, but in the rare event of a combination of the two conditions in the same individual the entire colon would lie on the right side. This was so in the case (post mortem) of non-rotation together with partial transposition of the viscera reported by Sandera.²⁸ Very real difficulties may be encountered in interpreting the varied appearances which may present themselves in such a rare combination. These appearances have been dealt with by Spitz³ who has reviewed the few cases in which the combined conditions have been found post mortem.

DUODENUM INVERSUM

The absence of the duodenojejunal flexure behind the stomach, and the presence of the duodeno-

jejunal junction in the right hypochondrium (see Fig. 1) have often been noted at operation in cases of non-rotation. But the presence of "right-sided duodenum inversum," as it has been termed, has on rare occasions been found where the second stage of rotation has been complete—i.e., in subjects in whom the small bowel and colon occupy their normal sites. According to Weinbren²⁹ (1934) only about 30 such cases are on record. It will be remembered that the duodenum itself takes no part in the actual rotation of the intestine, the normal curve of the duodenum being shaped by the growth of the head of the pancreas which develops on the left side of the duodenum as an outgrowth from it. The inversion of the duodenum is due to defective attachment of the duodenal mesentery or lack of subsequent fixation whereby the duodenum may remain mobile. Of the cases reported by Sandera,³⁰ in which, despite a duodenum inversum, the duodenojejunal flexure was present and situated to the left of the midline, 2 were operated upon; and, in addition to faulty fixation of the duodenum, a deformity of the head of the pancreas was found. Further examples of an abnormally shaped duodenum were encountered in the dissecting-room by Anderson,³¹ and in the operating-theatre by Armstrong,³² in both of which cases an abnormality of the head of the pancreas was also noted. Inversion of the duodenum, according to Sandera,³³ may be associated not only with abnormalities of the head of the pancreas, but also of the right kidney, portal vein, and transverse mesocolon. An abnormal mobility of the duodenum may however be present and give rise to symptoms without inversion and when the duodenojejunal flexure is in its normal position (Freeman³⁴).

Of the reported cases of inversion of the duodenum, some have been symptomless, while others have presented symptoms which have been ascribed to the condition. Sandera³³ holds the view that the presence of a mobile duodenum inversum may give rise to symptoms ascribable to dysfunction of the organs whose ducts empty into the duodenum, and states that the condition confers a predisposition to pancreatitis and cholecystitis. Three of Weinbren's cases gave a history of recurrent attacks of diarrhoea, and in several reported cases rapid passage of the barium meal through the alimentary tract has been noted. In 2 cases Weinbren conclusively demonstrated the mobility of the duodenum by showing the presence of right-sided duodenum inversum in the erect position, while the course of the duodenum altered so that it approximated the normal when the patients were radiographed in the prone position. This demonstrable mobility of the duodenum has also been referred to by Hürthle.³⁵ It is not always present.

The significance of right-sided duodenum inversum and the importance of its radiological recognition are that the condition indicates not only defective mesenteric attachment of the duodenum, but also the possible existence of the other congenital or acquired abnormalities already mentioned, which are frequently associated with it—abnormalities which may in themselves be unrecognisable by present-day X ray methods.

SUMMARY

(1) Reference is made to the surgical importance of anomalies of intestinal rotation and to the desirability of their pre-operative recognition. (2) Two cases of sinistrocolon due to failure of the second stage of rotation are reported. The X ray appearances throughout the gastro-intestinal tract are described.

(3) Minor degrees of defective mesenteric fixation in the third stage of rotation are common, but are not without surgical significance. A brief discussion centres round the description of a case of "left-sided cæcum." (4) Right-sided duodenum inversum may be unassociated with any other intestinal misplacement. Apart from the significance of the condition itself, it is often associated with other congenital abnormalities which cannot be detected radiographically, though they may produce symptoms. The recognition of duodenal inversion is therefore of importance and depends upon the radiographic or fluoroscopic visualisation of the duodenum throughout its length.

I am indebted to Dr. R. E. Roberts for his permission to publish these cases. My thanks are also due to Mr. H. F. Woolfenden and to Mr. R. Kennon for allowing me to discuss here cases admitted under their care.

INDUCTION OF CANCER BY CRACKED MINERAL OILS

BY DR. R. E. TWORT, M.D. Aberd.
AND MR. R. E. TWORT, B.Sc. Lond.

(From the Laboratories of the Manchester Committee on Cancer)

THERE is no gainsaying that the high compression internal combustion engine (the Diesel) is, for heavy motor vehicles, gradually replacing the lower compression engine, and it is not unlikely that in the relatively near future the same process of evolution will take place as regards the private motor vehicle. Apparently a few years will see the majority of the many thousands of motor omnibuses in service on the London streets propelled by the Diesel-type engine, and it is because we have foreseen this probable evolution that a few tentative experiments

in relation to the medical aspects of the subject have been carried out here during the last four or five years. It is our intention here briefly to point out a few of the indications that we have received from these experiments, especially in relation to cancer.

It has been definitely established for many years that apparently any organic material that is suitably retorted can be converted into compounds carcinogenic for the skin of animals, but it is of course not to be assumed that such compounds would be carcinogenic for the internal organs of man. It is necessary to bear in mind the fundamental difference between a mucous membrane and skin, with its attendant mucus and fat respectively, and it is not unlikely that the water-soluble derivatives of the fat-soluble carcinogenic skin compounds would play a more important part in carcinoma of the lung and alimentary tract than they do in carcinoma of the skin. Direct experiments in this connexion with sulphonic acid derivatives of the lowly carcinogenic Chrysene and a highly carcinogenic synthetic tar resulted in no reaction being observed on the part of the skin. This was not surprising, but, on the other hand, it may be well to record that an extensive squamous-celled carcinoma of the fore-stomach was observed by us in a single mouse among this particular 500 experimental animals. The tumour may, of course, have been a spontaneous growth, very rare examples of which are encountered in this variety of animal, but it is rather curious that the only specimen of its kind with which we have met among over 100,000 animals should have occurred in an experiment designed for this particular purpose.

The first real direct experiments undertaken in relation to our subject were those in which mice were exposed to the fumes arising from mineral oil, cracked on an electrically heated metallic plate.

One hundred animals were used in each group, group 1 comprising those painted on the skin with gas tar, while group 2 were kept unpainted as controls. Groups 3 and 4 were corresponding lots of animals kept in the ordinary well-ventilated animal house. The following results were obtained.

(a) *Skin tumours* in group 1 arose definitely earlier than they did in group 3, the carcinogenic potency of the tar being 80 and 18 respectively. Scrutiny of Table I. shows that the survival rate of the group 1 animals was relatively poor, but despite this the number of tumours in a given period of time was always above that found in group 3.

TABLE I

Group.	Tumour.		Total.	Average week of tumour appearance.		Malignant Lag.	Carcinogenic potency.			Survival rate for week (11th to 35th week).
	Benign.	Malign.		Benign.	Malign.		Benign.	Malign.	Mean.	
1	39	13	52	24.8	36.6	11.8	77	83	80	58.56
3	22	13	35	30.8	42.3	11.5	17	21	18	74.64

(b) *Lung tumours*, which are often reported as occurring frequently among normal mice, we found in not much more than 2 per cent. among some thousand or so of our animals examined. There was no definite evidence that in the experiments under consideration the oil fumes caused an increase in the incidence of lung tumours. Ordinary catarrhal changes are frequent in the lungs of mice, but with

the present animals these changes were definitely more marked among the group 1 and 2 animals than among those comprising groups 3 and 4.

(c) A limited number of blood counts were carried out. While no appreciable difference in members of the four groups of animals was noted as regards the red cells, there were indications of a higher average polynuclear count in the animals exposed to the oil fumes. Thus:

TABLE II

Group.	Animals examined.	Average per cent. of polynuclears.
1	17	23.8
2	9	34.7
3	30	22.9
4	13	19.6

A further line of investigation was with an oil recovered from the exhaust of an internal combustion engine. From about 1 cwt. of soot moved from the expansion chamber of a 36 h.p. stationary Rushton-Hornby high compression internal combustion engine about 3 per cent. of an oily, tarry material was recovered by extraction. A dilution of 20 parts of the oil and 80 parts of chloroform was applied to the backs of 100 animals in the ordinary manner. Unfortunately the survival rate was poor, the average number of animals surviving per week, from the 11th to the 35th week, being only 31.88. Consequently but few tumours were obtained, six in all, the first arising during the 24th week, and one only becoming malignant on the 42nd week, practically at the end of the experiment, when only a few survivors remained. The carcinogenic potency, calculated according to our methods, was 17, and as we have found that with 10 per cent. dilutions of highly carcinogenic mineral oils the relative potency figures obtained are directly proportional to the dilution, the carcinogenic potency of the pure recovered oil is considered as 85. This, of course, is a high figure for any mineral oil other than shale oil, and it is what one would anticipate in view of the temperature at which the oil must have been cracked. The recovered oil was also subjected to our injection test.¹

Owing to the obvious toxicity of the oil for the general animal economy it was only possible to utilise a 10 per cent. dilution in liquid paraffin. The refractive index fall more or less confirmed the findings as regards carcinogenicity obtained by skin application. The "violence test" for ascertaining the relative amounts of dermatitic and carcinogenic constituents responsible for the refractive index fall has yet to be performed. This latter test is based on the conception that the dermatitic constituents have a lower molecular weight and are more easily oxidised or hydrogenated by the animal than is the case with the carcinogenic constituents. Consequently the difference between inflammation and cancer in our experience we imagine may be essentially one of difference in violence of reaction on the part of the animal.

Some further observations we have made are that the lighter grade Diesel fuel oils are non-carcinogenic for the skins of mice, but a heavier grade tested was definitely carcinogenic. Several of the lighter grade only, each of which was applied daily to the interscapular region of 100 mice, failed to induce a single tumour, although dermatitis was evident, and they had a high toxicity for the animal economy in general. The oils in question had a very low viscosity, having

¹ Journal of Hygiene, 1935, xxxv., 125.

superficially the appearance of a highly coloured kerosene, negative results as to carcinogenesis being of course to be expected. The heavier grade Diesel fuel oil was the older type dirty-looking oily mixture with a kinematic viscosity of 13.7. When applied daily to 100 mice it induced 18 tumours, 3 of which became malignant; but when only two applications per week were made to a further 100 animals, a much more severe test, only a single tumour was observed.

Lubricating oils recovered from the sump of private motor vehicles were more carcinogenic than the original oils used for lubricating. Again, we have observed that the carcinogenicity of crude shale oils tends to decrease as the retorting temperature is lowered, but at the lowest temperature tested—namely, 400° C.—the oil was still carcinogenic. Three oils, cracked in the laboratory at 385° C. under 50 atmospheres pressure gave the following readings:

TABLE III

Oil.	Carcinogenic potency.			
	Before cracking.		After cracking.	
Liquid paraffin	0		28	
Texas engine	1		29	
Shale spindle	244		138	

indicating the gradual approximation of the carcinogenicity of the three oils after cracking.

CONCLUSION

If mineral oils and tars are instrumental in inducing carcinoma of the lung or alimentary tract of man it is probable that the constituents of the oils causing the trouble will be found to be dissimilar to those causing skin carcinoma. We anticipate that the molecular weight of the former would be lower than that of the latter, and would be possibly similar to some of those compounds which induce dermatitis of the skin of the animal. Our future investigations in this field will therefore be specially directed towards the examination of atomised refined oils in preference to crude, cracked products.

THE U WAVE OF THE ELECTROCARDIOGRAM

By E. HINDEN, M.B. Camb., M.R.C.P. Lond.
LATE OUT-PATIENT MEDICAL OFFICER AT THE NATIONAL
HOSPITAL FOR DISEASES OF THE HEART, LONDON

A SMALL upright wave, after the T wave, is sometimes seen in human electrocardiograms. Most modern text-books state merely that it occurs in early diastole, that probably it is due to the great vessels, and that it is of no importance. It was first described and named the U wave by Einthoven,¹ who thought that it occurred in systole and was pathological. Hering² considered that it was due to contraction of the truncus arteriosus, but this explanation does not appear to be substantiated by the work of Lewis and Rothschild³ on the time of propagation of the impulse in the ventricle. Lewis and Gilder,⁴ working on curves obtained from normal subjects, gave statistics of the U wave in health. They found that it was present in 90 per cent. of curves from lead II., its maximum height being 0.8 mm. and its average height 0.16 mm. It was also found, but less frequently, in leads I. and III. They pointed out that the U wave can have two forms: it can occur either as a sharp peak immediately after the termination of the preceding T wave

(at times, even, the U wave begins to rise before the downstroke of the T wave reaches the iso-electric level); or else it occurs as a bending of the whole of the T-P interval into a broad, shallow wave. These are later referred to as Types I. and II. respectively.

FIG. 1.—Lead II. Type I. U wave.

Two recent contributions on this subject may be mentioned here. Maekowa,⁵ working with strips of frog's heart, took simultaneous myographic and electrocardiographic tracings, and concluded that the U wave was due to prolonged contraction and delayed relaxation at the basal part of the ventricles. Clinically, he considered that the Type I. wave was normal and the Type II. abnormal. Trendelenberg⁶ found U waves frequently in lead II., and almost constantly in needle-leads taken directly from the

FIG. 2.—Lead II. Type II. U wave.

chest wall. He suggested the following three possibilities in explanation: (1) that it is due to the rapid current of blood in the great vessels at the beginning of diastole; (2) that it is due to the presence of fibres in the heart, which actively dilate it at the end of systole—the so-called "active diastole"; (3) that it is due to active systole of the aorta. However, he did not state which of these explanations he favoured.

The present inquiry was undertaken to see what new facts about the wave might be discovered.

There are here collected 104 patients showing a U wave of a minimum size of 0.5 mm. (In Table I., giving the heights of the wave in the various leads, some are recorded smaller than this minimum, but in every such case

3.—Leads II. and III. U waves in both leads.

there was a wave of the stipulated size in another lead.) Of these 104 patients, 86 were seen in out-patients by three of the consulting staff of the Heart Hospital during the years 1932-34; this is an incidence of 2.3 per cent., as 3744 new out-patients were seen in all by these physicians during that period. There are 109 tracings for analysis, as several tracings were taken from some of the patients.

The following examples illustrate the various types of U wave.

Fig. 1. Lead II. This shows the Type I. wave, that is, the peaked wave arising directly after the end of the

T wave. In one or two cycles the U wave upstroke begins before the end of the downstroke of the T wave. It was taken from a woman aged 26, who complained of tiredness, palpitation, and giddiness. She had a rheumatic history, and there was a soft systolic murmur heard all over the precordium, but no definite valvular disease was found.

Fig. 2. Lead II. This shows the Type II. wave—that is, a bending of the whole of the T-P interval. The patient was a woman aged 70, with a heart enlarged to right and left. She complained of a constant ache in

The U wave was found twice in lead I. alone, 28 times in leads I. and II., and 4 times in leads I., II., and III. It was found 47 times in lead II. alone, and 26 times in leads II. and III. In lead III. alone it was found twice.

CLINICAL ASSOCIATIONS

It happened that of the 104 patients, 52 were men and 52 were women.

TABLE II

Age of the Patients and their Clinical Condition

Classified by age:—			
Under 15 years of age	5		
Between 16 and 30	29		
" 31 .. 45	20		
" 46 .. 60	36		
More than 60 years of age	13		
The age of one patient was not stated.			
No evidence of cardiovascular disease	33	(32)	Per cent.
Arterio-sclerosis	22	(21)	
Rheumatic carditis	19	(18)	
Hypertension	12	(11)	
Thyrotoxicosis	5	(5)	
Post-toxic states	5	(5)	
Wassermann reaction positive	2	(2)	
Other cardiac conditions	6	(6)	

104

It will be seen from Table II. that the U wave is found in both sexes, at all ages, and in a great variety of cardiac diseases, as well as in health. There are only 2 cases in this series with a positive Wassermann reaction, and in neither patient was there any evidence, clinical or post mortem, of syphilitic aortic disease. This is rather curious, in view of the large number of sufferers from specific aortic regurgitation who are encountered in the hospital out-patient department. Of the 5 patients with thyrotoxicosis, no less than 3 had hypertension also. This condition, which is a comparatively rare one, is associated with a high systolic and a low diastolic blood pressure. If any inference can be drawn from these figures, it is that a high pulse pressure is favourable to the production of the wave, provided that this pressure is not due to disease of the root of the aorta. Disease in this region appears to be unfavourable.

In order to test Maekowa's suggestion⁵ that the Type I. wave is normal, and Type II. pathological, 100 tracings were analysed as to the form of the wave and the presence or absence of heart disease, with the following results:—

	No heart disease.	Heart disease present.	Total.
Type I.	15	30	45
Type II.	14	25	39
Indeterminate	4	12	16
	33	67	100

It will be seen that cases with or without heart disease are divided equally between the two types—that is, there is no correlation.

In summary, it may be said that the U wave is found in approximately 2½ per cent. of a large series of patients. The wave occurs in two forms, either as a sharp peak immediately after the T wave, or as a low broad wave occupying most of the interval between the T wave and the succeeding P wave. It has been suggested that these types are respectively normal and pathological, but no evidence for this is forthcoming from this series. The wave is found in health and in a great variety of pathological conditions, but I have not found it in syphilitic aortic disease, with or without aortic incompetence. With this exception, a large pulse pressure seems to favour the appearance of the wave.

I should like to express my gratitude to Dr. T. F. Cotton, Dr. J. M. H. Campbell, Dr. J. Parkinson, and

FIG. 4.—Lead II. Summation of the U wave with the succeeding P wave in cycles 3, 4, and 5.

the chest and acute pain after exercise. Her blood pressure was 210/110, and the diagnosis hypertension and angina pectoris.

Fig. 3. Leads II. and III. This shows a well-marked U wave in both leads. It was taken from a man aged 32, who was rejected for life assurance because of a soft systolic murmur. Clinically there was no heart disease.

Fig. 4. Lead II. This is a noteworthy tracing. It was taken from a woman aged 22, who complained of palpitation and an irregular pulse. Clinically there was no heart disease, the irregularity being due to premature contractions. The tracing shows tachycardia (rate=115) with pronounced U waves. In cycles 3, 4, and 5 only two waves can be seen between the successive QRS complexes. This is due to the summation of the U wave

FIG. 5.—Lead II. Auricular flutter simulating U waves.

with the succeeding P wave. It will be noted that the second wave in these cycles is higher than the P wave usually is, and that the duration of the cycle is less than usual; this can best be seen by comparing cycle 5 with cycle 6.

Fig. 5. Lead II. This is included to show the difficulty sometimes met with in distinguishing the wave. It is a case of auricular flutter, which closely simulates the Type I. U wave.

ANALYSIS OF THE TRACING

The 104 patients yielded 109 electrocardiograms showing this wave. Almost always, a patient who once showed this wave showed it well over a sub-

TABLE I

ARTERIAL EMBOLLECTOMY

IN A CASE OF BRACHIAL EMBOLISM

By VICTOR RIDDELL, M.A. Camb., F.R.C.S. Eng.
SURGICAL CHIEF ASSISTANT, ST. GEORGE'S HOSPITAL, LONDON

THE first successful case of arterial embolectomy in this country was reported in 1925; up till then nearly all the records of the operation had appeared in America and Scandinavia. Since 1925, 8 more cases have been described in England, and repetition in the medical journals of the symptoms and signs of arterial embolism has probably been responsible for its earlier and more frequent recognition. With this excuse, rather than with any claim to shed any new light on this interesting subject, I bring forward the following case.

CASE RECORD

The patient was a man, aged 57, and was first seen by Dr. J. A. Tierney, of Wimbledon. He complained of acute pain in the lower part of the left forearm and back of the hand, which came on suddenly at 9 A.M. while he was dressing. This was rapidly followed by increasing difficulty in movement, the forearm eventually becoming quite "dead." When Dr. Tierney saw him at 10 A.M. the patient was in a state of shock and covered in profuse perspiration. The whole of the left forearm and hand were marble-white. Slow coarse movements persisted, but fine movements of the fingers were entirely lost. The nails were cyanotic and return of colour after pressure very slow. There was no sign of radial or ulnar pulsation

FIG. 1.—Embolus blocking the main channel and involving the origin of the radial and ulnar collateral vessels.

but definite pulsation could be felt in the brachial artery 2 inches above the bend of the elbow. There was complete loss of cutaneous sensation in the lower half of the left forearm and hand. Heart: the apex-beat was in the sixth left intercostal space, 5 inches from the

lateral sternal margin, and the heart sounds were irregular in rhythm and muffled. The rhythm in the palpable brachial artery was also irregular, and a diagnosis of auricular fibrillation with brachial embolism was made. Morphine gr. $\frac{1}{4}$ was given, but this barely influenced the pain at all, and the dose was repeated two hours later. The pain persisted with great severity until 9 hours after its onset. The patient was admitted to St. George's Hospital at 11 P.M., under Mr. G. A. Ewart, 14 hours after the pain had begun.

On admission the initial state of affairs had considerably altered, the pain had almost entirely subsided, and what remained was felt in the back of the hand; the forearm

was mottled with blotchy areas of cyanosis, some degree of function had returned, and the anaesthesia was less complete, but the forearm was still cold. The radial and ulnar arteries were impalpable and inaudible, but the brachial artery could be felt 3 inches above the centre of the antecubital fossa, that is, 1 inch higher than where

FIG. 2.—Embolectomy and arterial suture resulting in narrowing of the brachial artery, with the risk of secondary thrombosis up and down the vessel.

FIG. 3.—Artery ligatured. Distal collateral vessels freed from the possibility of involvement by secondary thrombosis.

it was previously palpable, presumably owing to retrograde thrombosis.

The operation was carried out under local anaesthesia along the usual lines of arterial surgery, and an embolus straddling the bifurcation of the left brachial artery was removed through an incision over the upper part of the clot. Blood flowed freely on relaxing first the upper and then the lower control (a fine rubber catheter) but no obvious improvement in the colour or temperature of the limb or return of the radial pulse was observed, so that arterial suture rather than ligature was decided upon. The artery, already in spasm, was much narrowed by the suturing, and I was doubtful about its patency at the end of the operation. Additional periarterial sympathectomy was not deliberately performed.

Progress.—The wound healed by first intention and function, and sensation gradually returned until they were complete in ten days' time. The left radial pulse was not palpable until six weeks after the embolectomy, and then was not as strong as on the opposite side. The operation was performed on June 24th of this year and the man remains in good health up to the present. The heart is still fibrillating. (Fig. 1.)

DISCUSSION

I feel that the successful result of this case was due to the removal of the peripheral extension of the clot which was blocking the ulnar and radial collateral vessels, and for this reason it is always worth while doing an embolectomy even in late cases. The majority of successful cases have been operated upon within six hours, and the length of the interval before operation is recognised by all authorities as being the most important single factor in the prognosis. In the present instance embolectomy was not performed until 16 hours after impaction.

This case, like most others on record, showed the following characteristic features:—

- (a) *History* of previous cardiac disorder. The patient had rheumatic fever three times as a child.
- (b) *Aged 57.* The average recorded age is 50-60.
- (c) *Cause.*—The three common causes are cardiac disease, post-operative thrombosis, and generalised infection; in this case the patient had auricular fibrillation.
- (d) *The initial symptom* is almost always sudden severe pain, although occasionally numbness precedes the pain. The pain is characteristically felt distal, and sometimes far distal, to the site of obstruction, as in this case, and is

of no value for localisation other than to indicate the limb involved; gradually the pain moves distally in those cases in which an effective collateral circulation develops.

(e) The *anæsthesia* which is always present to some degree also depends upon the efficiency of the collateral circulation, and is equally valueless for localisation of the embolus.

(f) *Clinical triad* of "pain, pallor, and paralysis," to which must be added absent pulsation in the arteries of the limb below the site of impaction of the embolus.

(g) *At operation*, vigorous pulsation of the vessel proximal to the embolus, distension of the vessel at the site of the embolus, and contraction below. (Figs. 2 and 3.)

The historical aspect of this subject has been so well reviewed in previous papers by others that I must unwillingly make no further reference to it.

Of the 9 successful cases already referred to 6 were reported by Jefferson, 1 by Holdsworth, and 1 each by Banks and Larks; of these, 4 were associated with auricular fibrillation, 4 were post-operative, and 1 occurred in a patient with an ischiorectal abscess who was awaiting operation.

With regard to the operation itself at this level, in agreement with F. W. Holdsworth, I would suggest that the aim of the operator should primarily be to establish a proper collateral circulation rather than to concentrate on the hope of re-establishing a flow through the main channel, an occurrence which, as far as one can judge from an isolated case, probably never occurs after suture in the narrow arteries of the upper limb. This will best be achieved by removing all extension of the clot in the main vessel from any large branch or branches and by ending the operation by a procedure which minimises the chance of future involvement of the collateral circulation.

To effect this, ligation of the artery immediately above the site of incision is suggested in all cases of brachial embolism, provided that before this is carried out evidence of a good collateral circulation can be demonstrated during the operation. That such a circulation is in action may be assumed if (1) after removal of the clot, and with the artery controlled above and below the opening into its lumen, the patient remarks that the limb feels warmer (which will also be apparent to the operator) and (2) blood flows from the lower end of the vessel on releasing the distal control.

The advantage of ligation, apart from its simplicity, is that it precludes recurrent thrombosis at the site of the previous impaction and incision, where the vascular lining has been damaged, and of secondary thrombosis from here. It has also been conclusively shown by Wolf that there is less risk of gangrene developing after arterial ligation than when the obstruction is due to an embolus, and furthermore the chances of gangrene are smaller after ligation of the arteries of the upper than of the lower limb.

If arterial ligation is decided upon, two ligatures will of course be required, one above and one below the site of incision. It should be noted that the incision in the artery should be made if possible below the level of the embolus, should not be longer than one centimetre, and should not be made opposite the origin of a large branch.

ARTERIAL EMBOLISM.

By G. R. GIRDLESTONE, B.M. Oxon., F.R.C.S. Eng.

HON. SURGEON TO THE WINGFIELD-MORRIS ORTHOPÆDIO HOSPITAL, OXFORD

A MONTH ago I was urgently sent for by Dr. W. L. Wainwright of Henley to see a patient at Wargrave. This was a man of 71 who for some years had been bothered by mild intermittent claudication. This year he had been rather better and had been shooting over dogs in Scotland in August. But the morning before I saw him he had felt some pain in his left thigh, and tried to walk it off unsuccessfully. In the afternoon he went to London. The pain continued and in Paddington Station on the way home the pain suddenly became very severe, he fainted and fell, bruising his forehead. He was brought home, the severe pain continuing. This got even worse at night, but he bore it in stoic fashion only sending for Dr. Wainwright in the morning. Dr. Wainwright found his left lower limb pale and cold and was unable to detect any pulsation below the bifurcation of the femoral artery. I saw him at 11 A.M. and found him as his doctor had described. Pulsation was present about the level of Poupart's ligament but none below. Motor paralysis was incomplete. The pain was severe but a little better than at its worst. I agreed with Dr. Wainwright's diagnosis of an arterial embolism at the femoral bifurcation.

The patient was transferred with the least possible delay to a nursing-home at Reading, where all preparations for the operation had already been made through the ready help of Mr. F. H. Aitken Walker who was also kind enough to assist me in the operation. The patient was taken straight into the theatre. I made an incision with its centre over the bifurcation of the femoral artery. Under normal circumstances it is easy to find and expose an artery. The pulsation can be felt and seen; but where there is no pulsation one misses its guidance very much. I approached the artery with caution, palpating it gently to and fro from the pulsating common femoral to the non-pulsating superficial and back, so as to identify exactly the whole length of artery with which I had to deal. As I was doing this the pulsation suddenly returned throughout its whole length. Within a few seconds the patient expressed an immediate relief from the pain which had been severe and constant, and said that the leg felt quite different. Dr. Wainwright at the same time found that pulsation in the posterior tibial had returned. It was clear that our object was attained so I closed the wound. Within a few minutes the last trace of his pain had gone and before long the whole limb was warming up. A quarter of an hour later (after his return to bed) both legs were equally warm, and half an hour later the affected leg was warmer than the other.

His convalescence was uneventful; he complained of some stiffness in the posterior muscles of the thigh, but this passed off in the second week as soon as he began to move his leg about in bed. Since then he has done well. I saw him on Oct. 18th. There was a little wasting and loss of tone in the muscles of his left thigh. He has already returned to almost all his ordinary activities. He is still occasionally bothered by the old intermittent claudication.

I conclude that by sheer good luck my palpation moved the embolus from the bifurcation of the femoral into the profunda femoris. What was in this case a happy accident might perhaps on other occasions be an aim, and palpation directed toward the persuasion of an embolus into the less important branch might be recognised as a manoeuvre worth trying before opening the artery.

NOTE

I sent the above report to Mr. Geoffrey Jefferson of Manchester, as I had very much appreciated

hearing his admirable address on the subject given at Bournemouth in 1934. He reminded me that in the last paragraph of his paper¹ he had recommended attempting to massage the clot into the subsidiary vessel. He writes as follows:—

"I have referred to such a side-tracking as the explanation of the sudden recoveries that may undoubtedly occur in embolisms before such time as the clot becomes adherent to the intima, but it seems to me that a practical hint might be taken from these happy chances, and that when it does not happen of itself we should try to compel it. The first step would therefore be the exposure and temporary control of the main vessel above and below the embolus in the ordinary, followed by a deliberate attempt to massage the clot into the subsidiary, branch. If this failed the operation would be proceeded with on normal lines and the artery opened."

The only difference between his recommendation and my experience is that in my case the manipulation succeeded (fortuitously) without temporary control of the vessel, and I imagine that in my case there may have been an advantage in avoiding even temporary compression of an oldish artery. Furthermore I would suggest that there is more likelihood of coaxing the clot into the artery if the fingers are aided by the pulsating pressure of the blood. But if temporary control of the main trunk is avoided the clot may be inclined to go the wrong way, therefore one of the fingers following the embolus up the main branch had better remain in place just below the bifurcation. A finger can be the gentlest means of control, and can be applied without raising the artery from its bed.

A CASE OF ATROPINE POISONING

By VIVIAN M. MÉTIVIER, F.R.C.S. Edin., D.O.M.S.

HON. OPHTHALMIC SURGEON, COLONIAL HOSPITAL,
SAN FERNANDO, TRINIDAD

ATROPINE instilled in watery solution sometimes causes poisoning in children attending the outpatient eye department. The signs and symptoms are reddening of the face, dryness in the throat, nausea, and a quickened pulse-rate. There is usually some excitement, and occasionally mild delirium is seen with hallucinations. According to the dominating passion, pennies and marbles may be the subject of illusion, and the delirium is generally of a pleasing kind. Great restlessness passing on to delirium, after cataract extraction, calls for cessation of atropine instillations, among other measures. The following case of an old lady developing hallucinations after using atropine drops for treatment of cyclitis is somewhat unusual.

A. B., aged 74, European, had a left cataract extraction in 1918 with good visual result. There is a mature cataract in the right eye. She was first seen by me with an attack of iridocyclitis in July, 1930, the left eye being affected. The attack recurred in September, 1932, May, 1933, and in July, 1934. On each occasion atropine drops, 1 per cent., were used twice daily, applications being made to the left eye only. Good recovery resulted after each attack, only a few very small whitish spots of keratitis punctata eventually remaining.

On June 8th, 1935, she came to see me again with another attack of cyclitis in the left eye. She also complained of some discomfort in the right eye, but there was no ciliary or conjunctival injection in that eye. On further examination however a few old spots of K.P. were seen. Atropine drops, 1 per cent., were ordered for both eyes twice daily; and on being questioned about the

drops that had been used the previous year I consented to their being instilled, provided that the solution was quite clear. (It is my practice here to have all eye drops made up in a saturated solution of chlorotone in order to prevent fungus growth.) On the following morning the patient's daughter reported that her mother had been a little excitable during the night and that she had seen imaginary objects. The patient, who is still active—and she looks well for her years—affirmed that she had seen, among other things, a young woman sitting at the foot of her bed. She stated that "she was quite a pleasant young woman," and added with emphasis, "I was curious and very interested to learn what she was doing there." She also said that her face had felt quite flushed and that her throat had become very dry.

It is to be noted that the delirium was of a pleasing kind in this case, which suggests that the delirium that develops after cataract extraction, as a post-operative complication, may not be due in any way to atropine. A private patient of mine in Port-of-Spain developed delirium tremens in 1932 the day after a cataract extraction. He imagined that Chinese men came into his room to worry him and he made attempts to fight them. He was allowed to get up and walk about in front of his bed with only a perforated aluminium shield to cover the eye that had been operated on. Hyoscine and morphine were resorted to, and he made a good recovery with very serviceable visual result. Atropine instillations were not discontinued in this case. It is possible that in the case of the old lady the atropine drops may have increased in strength, for they were made up a year previously and had probably lost fluid by evaporation. It was also the first occasion on which atropine drops were ordered for both eyes. In any case here is reason to make us still more careful in the use of this valuable and powerful drug.

FOREIGN BODY IN MALE BLADDER

By JAMES COOK, F.R.C.S. Edin., D.P.H.

DEPUTY MEDICAL SUPERINTENDENT, BIRKENHEAD
MUNICIPAL HOSPITAL

FOREIGN bodies of any considerable size introduced into the male urethra seldom (for anatomical reasons) get beyond the membranous portion. The following case is therefore unusual.

A youth of 18, somewhat retarded mentally, was admitted to Birkenhead Municipal Hospital on May 14th, 1935, complaining of lower abdominal pain, dysuria, and much frequency of micturition of some five weeks' duration. There had been no vomiting or intestinal derangement and the possibility of venereal infection was denied. The temperature on admission was 99.4° F. There was suprapubic tenderness and the prostate was enlarged, soft, and tender. The urine contained albumin and red blood corpuscles, but the only organism discoverable was *Bacillus coli*. Radiography was carried out to exclude vesical calculus and the radiologist's report was that there was no evidence of renal or vesical calculus, but that there was the stump of a pencil in the rectum. On being questioned the patient stated that he had swallowed the pencil.

Rectal examination failed to confirm the X ray findings and the hamaturia persisting, a cystoscope was passed on May 16th. The bladder was acutely inflamed and was found to contain the suspected foreign body, which was removed by the suprapubic route. Recovery was uninterrupted. The youth finally admitted that he had pushed the pencil along his urethra some five weeks previously, taking twenty minutes to complete the manoeuvre. The specimen, covered with phosphates, measured $1\frac{1}{2}$ in by $\frac{1}{2}$ in. and stripped of phosphates measured $1\frac{1}{2}$ in by $5/16$ in.

I am indebted to Mr. R. A. Grant for permission to publish these notes.

MEDICAL SOCIETIES

BRITISH PSYCHOLOGICAL SOCIETY AND
MEDICO-LEGAL SOCIETY

At a joint meeting on Nov. 20th of the Institute of Medical Psychology with the medical section of the British Psychological Society, the chair was taken by Dr. EMANUEL MILLER, president of the latter, and a discussion on

Nullity and Impotence

was opened by Dr. E. A. BENNET. Very few marriages, he said, were annulled—about 38 per 100,000 in England and Wales—and other reasons than impotence might be advanced in some of these. The medico-legal conceptions of impotence in relation to nullity suits were by no means clearly defined; the work of the psycho-pathologists remained almost unnoticed by writers on the subject. Impotence was caused by certain physical defects, and if these existed, unknown to the other party, at the time of marriage, the contract might be rendered void. The defects could be found on examination, and the medical witness could state emphatically that copulation was permanently impossible. In functional or psychical impotence no physical defect was observable on examination, and to this form of impotence, Dr. Bennet said, his paper would refer. In a woman it might evoke observable changes, as in vaginismus and genital hyperæsthesia. Psychogenic influences were the commonest causes of impotence in marriage and, if irremediable and not disclosed, should be grounds for nullity. F. J. McCann had declared that a medical witness was not justified in diagnosing impotence in the absence of physical defect, and J. Glaister said that from the medico-legal aspect mental causes did not rank as causes of impotence. Nevertheless, any cause creating a barrier to coitus legally gave grounds for declaration of nullity, and decrees had been given when a man was found to be impotent only quoad his wife and not necessarily with other women. The term "selective" should be substituted for "relative" to describe impotence in one partner of a particular marriage.

It was possible, Dr. Bennet maintained, for a medical witness to make a dogmatic statement on the question of impotence in the absence of injury, disease, or defect. If the wife could not offer evidence of virginity and aptitude, nullity proceedings might fail in the absence of any evidence of the selective impotence of the man. A complex series of influences was at work in the married state, social concomitants being added to instinctive urges. Friction in that complicated unit, the married couple, might be easy of access or difficult to locate and remove. Friction upset smooth running, stresses and strains were observed, and incompatibility of outlook was reached. Impotence might be found at any stage of this process. Conscious likes and dislikes were important. Perhaps for conscious, often for unapprehended, reasons the emotional lives did not blend. Both partners must be interviewed. Adler's views were helpful: he held that impotence was traceable to a lack of liking and training for relations with others. Impotence was never found alone, and the individual's life must be surveyed; if the interview revealed no other psychoneurotic symptoms it would be rash to diagnose impotence. Inquiries should be made about the past and present attitude to the parents.

Dreams often threw light on unconscious motives at work.

In the majority of cases impotence cleared up with suitable treatment and a coöperative partner, but the suggestion of a nullity suit introduced a new and emotionally disturbing element which might well prevent cure. The patient's humiliation was thereby made public, and he had lost the coöperation of his wife. Impotence in a woman was rare, but she might find coitus too repugnant, or refuse it for fear of pregnancy. This might be grounds for nullity but was not impotence, and might equally well be found in the man. Mental health in such cases of refusal might be quite sound, but nullity might be declared on legal grounds. If, however, a man or woman consciously coöperated up to a point and was then unable to continue as a result of incomprehensible feelings, he or she had an unconscious mental conflict. It would be the duty of the medical witness to determine whether the impotence were curable or not. If there was mutual hostility treatment would be unavailing, but if there was goodwill and the psychoneurotic partner were willing to undergo psychotherapeutic treatment, the chance of cure was high. There was a wide gap between legal and psychological conceptions. In nullity cases obscurity could only be relieved by the medical witness, whose duty it was to appear and to make dogmatic statements.

Dr. ADRIAN STEPHEN commented on the inherent difference between the medical and legal professions and their approach to this problem. Impotence was not a simple entity. Considering the complicated path of development of sexual potency, it seemed more necessary to explain how anybody ever achieved normal sexual development, rather than its failure. To some extent everyone had failed. In some cases impotence depended on the connexion between the genital function and some other bodily function such as urination. In young children urination could be used as a means of self-assertion and attacks on enemies. By its identification with the sexual act this became an act of aggression instead of love, and so was inhibited. Similarly impotence might be produced by inhibitions originally imposed on sucking or defæcation. Sucking was one of the earliest physical expressions of the emotion of love and anything which interfered with the early forms might have disastrous effects on the later. An infant frustrated in suckling might approach the breast aggressively and want to bite or destroy it. A loved object in such a way became a feared, hated, frustrating, or revengeful object. The whole love life of the individual might be developed on such a pattern that what would normally be physical expressions of love became expressions of hatred, and potency might be inhibited by unconscious fear of retaliation or of soiling or injuring the loved object. The result might apply to all women, or the man might divide women into two classes: the idealised and pure with whom intercourse was impossible, and the degraded whom it was permissible to injure.

Another class depended on the œdipus complex: the unconscious fear of a rival. In such cases a possible third party had to be considered, but very often the fear was directed less to a real external figure than to a reincarnation in the man of the imago of a parent or part of a parent. Such

reincarnations might also lead to unconscious desire to limit the parents' potency. Similar factors were found in the woman. The partners might play into each other's hands. The attraction of two people depended on factors quite beneath the level of consciousness and incompatible with the conscious wishes, and the very factors which brought about a marriage might also tend to spoil it.

Mr. GEOFFREY TYNDALE said that many nullity cases never came into court, but apparently it was commoner for nullity petitions to be brought by husbands. In law it must first be proved that the marriage had never been consummated. If a man's petition for nullity, when the wife wilfully and persistently refused, were dismissed he could only get his freedom by providing her with evidence for divorce; she then had one-third of his income for the rest of their joint lives. There would be no justice until such refusal were made grounds for dissolution of the marriage or for nullity without proof of incapacity. Sir Samuel Evans had tried to grant decrees for wilful and persistent refusal but the Court of Appeal had stopped him. Counsel would welcome medical assistance, but were hindered by "medical privilege" which prevented the doctor from revealing his evidence before he entered the witness-box. He might be quite right in refusing, but counsel dared not call him. A change in the law could be made by the instructed opinion of doctors and lawyers together. In nearly every nullity case the petitioners were rather "freaks," and seemed almost incapable of telling the truth, although they thoroughly believed the tales they told.

Mr. S. E. KARMINSKI said that in cases of nullity and impotence physical defects were very rare. Medical inspectors of the court were therefore in a great difficulty. The court had to be satisfied that the marriage had in fact not been consummated and that attempts had been made to consummate it. If the marriage had not been consummated the court would readily assume that the cause was failure of one party to play his part. Courts were quite willing to recognise psychic causes. In some cases decree of nullity was given to both parties. Impotence was about equally distributed between the sexes. A woman might be untouchable because she had been taught that anything sexual was disgusting; because she confused the sexual act with the lavatory side of human nature; or because she disliked being touched by anybody. In the man a common cause was masturbation; often he could not be bothered to change his practice and became completely self-centred. In other cases previous venereal disease caused fear of infecting the wife. General hysteria might be present in either sex, the mere excitement causing loss of control and impotence. Another variety was anxiety lest he should be unable to perform the sexual act. Wilful refusal ought to be grounds for annulling the marriage. Courts were very willing, however, to infer impotence from violent forms of refusal, so that in fact wilful refusal mattered less than it appeared to from the decisions of the Court of Appeal.

Dr. H. CRICHTON-MILLER welcomed evidence of dissatisfaction with affairs in this department among members of the legal profession. Most doctors had experienced disappointment in their attempts to get across to the legal mind the things which really mattered in marital cruelty and failure. He asked what the essential justice was that the law tried to

express. It looked as if the law made two invalid assumptions: that impotence and frigidity were absolute conditions; and that these things could be objectively established about either partner. Could one defend as a legal marriage one in which one partner knew himself to be infertile before or had himself or herself sterilised immediately before marriage without revealing the fact? In any other department this would be breach of contract. What happened if there was antenuptial agreement to have no issue and afterwards one partner wanted children and the other still refused? What injustice was to be said for a marriage without coöperation as to children? Legally marriage seemed to be tied down to coitus—a very narrow aspect of it.

The CHAIRMAN thought the "freakishness" of both sides and the incidence of lying ought to be taken into account in legal proceedings, and would encourage coöperation with the psychologists.

Mr. Registrar NORBURY said if fertility were to be a ground for nullity great difficulties would be encountered. It would be very difficult to determine fertility, but consummation could be ascertained fairly easily. Marriage was a special form of contract; refusal was not a ground for nullity. The only ground at present was incapacity to carry out the contract. The courts were only too ready to infer incapacity from persistent refusal, and there would be no point in adding the latter as a cause for nullity. Absence of consummation and want of consent were the only grounds recognised by the Roman Catholic Church. The law worked smoothly at present and hard cases made bad law.

Dr. S. H. BELFRAGE said the lot of the medical inspector was not a happy one. He had to furnish a report stating that the man was apparently capable of intercourse, and could not go beyond the external genitalia and nervous system. Testicular sensation might be investigated but was not a safe guide. He might therefore have to state that a man was apparently capable when he was well known to be quite incapable with his wife—which was all that the court was concerned with. The inspectors were not now allowed to speak of anything outside the physical examination in their reports. There was no difficulty in obtaining a decree where there was wilful refusal. In 100 recent cases there were 55 men and 45 women obviously to blame. Men fell into the following categories: refusal to attempt; wish with complete failure of desire; failure of erection, with desire; and erection but premature ejaculation—the greater majority. The courts had not yet decided how far penetration must take place. Among the wives there were cases of refusal; active resistance; and severe pain owing to conformation of the parts, usually associated with refusal to see a surgeon. In some cases mutual masturbation was preferred; or there was physical incompatibility of the genitalia. The great majority of cases were based on mutual difficulties and were due to ignorance.

Dr. J. R. REES commented on the difference between the legal and the psychological points of view, and wished that a series of articles taking the matter further might be published. Penetration was not consummation to the psychologist. The subject had hardly been touched.

The openers briefly replied, Dr. STEPHEN pointing out that reform of the law was not the business of lawyers but of electors.

MEDICAL SOCIETY OF LONDON

At a meeting on Nov. 25th, Prof. G. E. GASK, the president, being in the chair, a discussion on the

Use and Abuse of Insulin

was introduced by Dr. R. D. LAWRENCE. Insulin was, he said, discovered 14 years ago, and its use had been steadily increasing for 12 years; yet, though many papers had been published on the physiological action and therapeutic use of this pancreatic hormone, the exact mode of its action and the extent of its usefulness had not yet been settled. The physiological action of insulin was most clearly seen in diabetes, in which disease it removed, only however for a short time, all the metabolic defects. These defects were, essentially, a failure to burn and store carbohydrate food in the tissues, with resulting hyperglycæmia and glycosuria, and a failure to metabolise fats. If the injection given was a large one it abolished the diabetic process in a few hours, reducing the blood-sugar, refilling the depleted glycogen store in the liver, to a less extent in the muscles, and at the same time caused the ketosis to disappear. His own view was that insulin only performed one step in the complex carbohydrate chemistry. He did not know whether it should be called a hormone, a catalyst, or an enzyme. Insulin had been advocated in a number of other conditions. When it was injected into a non-diabetic the blood-sugar was always lowered, and if enough insulin was given hypoglycæmia was produced. When given fasting, 10 units generally caused symptoms of hypoglycæmia: 20 units would within two hours cause severe symptoms which could be prevented by giving carbohydrate by mouth. Hunger was a very common and marked symptom, and it could be turned to good use in stimulating appetite where that was needed. After doses given at 11 A.M. a number of students developed such an appetite that they complained of the expense of lunching. The main indication for the use of insulin was, however, diabetes mellitus. It should be used whenever the utilisation of carbohydrate by the diabetic was insufficient to maintain the weight, health, and energy which life demanded. Its use was essential in coma, and for the continued welfare of most cases under 40 years of age; also in all cases of diabetes in childhood. Many elderly mild cases would be the better for it, chiefly for warding off complications, but many others did not need it.

The main difficulty, which led frequently to the misuse of insulin, was the fact that its action was quantitative, and that patients on similar diet value required very different doses of insulin to control the glycosuria; some needed 10 units daily, others up to 100 units. The commonest error made was to give too little insulin, when the patient derived little benefit from his daily injections. If given too much he was rendered wretched by the hyperglycæmic symptoms. The dose must be an individual one for each patient, and reviewed from time to time for the same patient. In diabetics careless of their diet an attempt to control the glycosuria completely by large doses rendered them liable to serious overdose when they ate less carbohydrate than usual. With two doses of insulin, each of 20 or 30 units, given twice daily, enough carbohydrate would be metabolised to maintain fair health and keep ketosis at bay. In France the practice of giving short intensive courses of insulin and then stopping the injections might lead to rapid improvement in

strength and weight, but at the risk of coma between the courses.

Insulin had proved such a success in diabetes that there was a tendency to try it for every metabolic irregularity. Seeing that normal people produced sufficient insulin of their own when carbohydrate was given, there was room for scepticism about the results of adding small amounts of insulin to large quantities of sugar. Some had used insulin to fatten the thin, to combat anorexia, and to prevent vomiting. He doubted whether insulin injections could make normal people utilise their carbohydrate any better. But it could promote appetite and even force the anorexic patient to eat. Insulin had been widely used for tuberculosis, and good results on appetite and weight had been published. Insulin could legitimately be used in conditions, such as prolonged vomiting in pregnancy or after anaesthetics, causing severe ketosis. He was the first to employ it in Graves's disease, a katabolic disorder associated with over-activity of the sympathetic system. When advocated for all sorts of toxæmias and septic conditions it was often a question of giving a little insulin with much glucose; and the insulin often got the credit deserved by the sugar.

The glycogen content of the diabetic heart, unlike that of the liver and skeletal muscle, was not reduced but rather increased above normal, showing that the carbohydrate metabolism of the heart did not depend on insulin for glycogen formation. Nevertheless the diabetic heart utilised much more glucose when insulin was given, and the heart often became surprisingly more efficient when insulin was given to diabetics. Conversely, partial heart failure and anginal attacks had sometimes been induced in myocardial and vascular degeneration when the sugar content of the blood was too quickly reduced.

Dr. GEORGE GRAHAM said that the deaths from diabetes in England and Wales for the past ten years had been steadily increasing; in 1900 about 2800 were recorded, in 1913 the number was 4200. In 1917 there was a sudden decrease to 3600, and the figures remained fairly stable until 1920. In the last two years before the insulin epoch the number of deaths from the disease nearly equalled the figure for 1916. Each year since then, with one exception, had seen an increasing number of deaths recorded. Last year the female deaths from diabetes exceeded the male. A similar increase was noted in other countries and no doubt apparent increases were due in part to more accurate filling up of death certificates. It was pertinent to ask why so many children and young persons died from diabetes. In the last few years none of the speaker's young patients had died of it. He feared that in small towns and villages remote from laboratories patients did not receive enough insulin. There was, he thought, a legitimate use for insulin in all cases in which the blood-sugar was raised. Such a rise occurred in association with the use of an anaesthetic, especially if accompanied by any degree of asphyxia. Much depended on the kind of anaesthetic; when open ether and chloroform were used it was wise to give 5 or 10 units of insulin, though some patients vomited in spite of it. The patients needed fluid, sugar, and salt, which could be given intravenously. The vomiting of pregnancy, if mild, was easily treated by diet and a careful régime; severe vomiting should be dealt with in the same way as post-anaesthetic vomiting. In toxic goitre insulin had no effect in reducing the toxicity, though if the blood-sugar was raised insulin would improve the general health. The chief abuse of

insulin was, he thought, abstaining from giving it, or not giving enough, especially if the patient was really ill. Insulin was sometimes wrongly given to patients who had a renal glycosuria with normal blood-sugar. Except in emergency insulin should not be given until a firm diagnosis had been made. Patients with diabetes might also have a lowered threshold for sugar, when urine tests became difficult. Severe attacks of hypoglycæmia were due usually not to a wrong dose but to a sudden improvement in the diabetic condition, or to a sudden bout of exercise. Most patients recognised the attacks early and treated them with sugar, but a few had awkward symptoms, such as incoördination, which might simulate drunkenness and fits. In the presence of severe hepatitis it was necessary to give extra glucose, so as to increase the glycogen in the liver; an ounce or two of sugar might well be given before injecting novarsenobenzol. Success had recently been claimed from the use of insulin in long-standing cases of cirrhosis of the liver. Severe and refractory boils might yield to small doses of insulin.

Dr. FRANKIS T. EVANS related a series of blood-sugar tests he had made some years ago during surgical anæsthesia. In the case of chloroform alone the sugar did not rise so much as when ether alone was given; with chloroform the rise was from 100 to about 125; while with pure ether it was to 180 and 200. The highest was after gas-and-ether. After gas-and-oxygen the rise was not more than to 150. He was not aware that his patients were asphyxiated, but the gas-ether sequence was suggestive of that.

Sir JOHN BROADBENT spoke of patients in whom diabetes started late in life. Some of them could get on well as long as they did not produce much sugar and were careful about their diet. Others asked for a more liberal diet, supplemented by the use of insulin. The higher scale of mortality in women patients than in men was, he thought, due to difficulty in carrying out a fixed régime. A woman diabetic might take time off and accept invitations to tea. In later life some diabetics had kidney trouble which no amount of insulin would relieve. Many went on for years with intermittent diabetes and albuminuria.

Sir WILLIAM WILLCOX said those with experience of hospital work knew elderly people classed as diabetics who did not die of diabetes but of arterio-sclerotic changes associated with glycosuria in old age. Often, too, there was some chronic interstitial nephritis. In 1921 he had pointed out the effect which toxic conditions had on the course of insulin administration. If a diabetic patient contracted influenza or pneumonia the dose of insulin needed to be greatly increased. That applied also to focal infections. One of the abuses in the employment of insulin was the treatment of glycosuria without thorough investigation. In some patients with focal abscesses there might be a sudden development of glycosuria; when the sepsis cleared up there was no longer need for insulin.

Dr. LAWRENCE, in reply, said that if elderly diabetics could stand 100 grammes of carbohydrate they did not require insulin; those on 50 grammes were not in such good health as they should be. The question was best answered by a consideration of the amount of sugar and acetone in the urine. If on 50 grammes a patient was reasonably well, if he did not need to live a life of full activity, and if no acetone was detected, there was no need to insist on insulin. If acetone was present it would be well to raise the value of the diet and give small doses of insulin. He agreed that women diabetics were more difficult to treat than

were men; a woman of 50 to 60 years as a rule exercised less control over diet than did a man of the same age. He did not see much complicating kidney trouble. Though traces of sugar and albumin were often found in these old cases of diabetes, they went on comfortably for years. If the amount of sugar in the urine was not controlled such cases were likely to develop retinitis and widespread capillary degeneration, showing itself in the leakage of albumin from the kidney and possibly gangrene of the feet.

ROYAL SOCIETY OF MEDICINE

SECTION OF TROPICAL DISEASES AND PARASITOLOGY

Dr. C. MAGARINOS TORRES (Rio de Janeiro) delivered the Lloyd Roberts lecture at a meeting of this section held on Nov. 25th, with Dr. PHILIP MANSON-BAHR, the president, in the chair. His subject was

The Pathology of Alastrim and the Variola-Alastrim Problem

The name "alastrim," he said, was a Brazilian term meaning something which spread from place to place, and the disease was very widespread. He described a small epidemic among soldiers in Rio de Janeiro. The clinical manifestations had been typical: the usual appearances of small-pox but without toxæmia and prostration. The suppurative stage of the eruption was attained sooner than in small-pox, but the smell was never offensive. There had been one death, from acute heart failure. There had been no subsequent pitting or scarring, but only a deeply pigmented spot. A study had been made of the inclusion bodies of alastrim and variola in the rhesus monkey. Extreme variations had been noticed. When small and discrete, these bodies looked very similar in both viruses, but in the later stages definite although slight differences could be identified. Alastrim bodies were usually single, even in advanced stages, and were about the size of the epithelial nucleus. Variola bodies were usually found in large numbers, leading to extensive vacuolation of the epithelial cytoplasm. Alastrim bodies regularly stained a deep blue when small, turning to greyish-blue when they attained the size of a nucleus, but small-pox bodies stained very capriciously, sometimes being eosinophil though usually blue. Their most characteristic feature was the presence within one cell of some pink ones and some blue ones. In only one instance had such polychromatophilia been found in alastrim inclusions. Moreover, intranuclear inclusion bodies had not been found in skin lesions induced by variola, although they had been found occasionally in alastrim lesions, revealing a peculiar retiform appearance. With Unna's hæmalum and safranin method, alastrim bodies were stained faintly blue-violet, but vaccine bodies, like the nucleoli, were strongly safranophilic and deep red.

The elementary bodies described by Paschen were now generally regarded as real micro-organisms and the ætiological agent of variola-vaccinia. Large numbers of these bodies had been demonstrated in smears from human and monkey cases of alastrim skin lesions. These were indistinguishable from those found in small-pox, but the cytoplasmic and intranuclear inclusion bodies were clearly distinguishable, in the human as well as in the monkey patient. Cytoplasmic inclusions in human alastrim were often

juxtannuclear, the nucleus preserving a normal outline. Sometimes the cytoplasm was normal, sometimes there was a halo of refraction around the inclusion. Unna's method revealed them as non-safraninophilic; and they showed basophilic properties with hæmatoxylin and eosin. Intranuclear inclusions were less typical than in other diseases and presented a peculiar retiform appearance with typical margination of the basichromatin. In human small-pox, cytoplasmic and intranuclear inclusions had been found in large numbers in epithelial cells. The two types did not occur within the same cell. Cytoplasmic inclusions manifested deep staining with safranin, prevalent acidophilia, and multiplicity of inclusions of different shapes and sizes within the same cell. There were three types of intranuclear inclusion in human small-pox: an irregular mass or masses of acidophilic granules within a relatively normal nucleus; a homogeneous or partially chromophobic inclusion taking up the entire nucleoplasm; and one or more clear ovoid or spherical acidophilic bodies with very small multiple chromophobic areas, the linin reticulum having disappeared.

Alastrim had been diagnosed by inoculation of the cornea of the rabbit. The virus was less resistant to desiccation than that of small-pox, and so Paul's original technique for its collection was inadvisable. A positive reaction in the cornea was manifested by tiny greyish-yellow prominences or uniform thickening along some of the incisions. The features described by Paul in testing for small-pox were not found. Microscopically there was a lack of arrangement and proliferation in the anterior corneal epithelium, and sometimes interstitial oedema, but very little surface bulging. Cytoplasmic inclusion bodies were found in every positive case. Paul's test in alastrim was therefore weak, inconstant, and easily distinguishable from the same test in small-pox.

In some respects alastrim held an intermediate position between small-pox and chicken-pox. Epithelial cell formation was common, as in varicella, and balloon degeneration of the cells of all the layers of the stratum germinativum was found. In small-pox the balloon degeneration was confined to the bottom and sides of the vesicle. A pathological process was constantly found in the corium in alastrim, as in chicken-pox, but the alastrim vesicle occupied the top only of the Malpighian layer, as in small-pox. In varicella intranuclear inclusion bodies only—not cytoplasmic—had been demonstrated.

The development of the alastrim skin lesion had been watched carefully. It began with proliferation of the epidermis upward and downward, but with few mitotic figures. A surprising number of Malpighian cells contained cytoplasmic inclusion bodies at this stage. Their nuclei were distinctly swollen and small vacuoles appeared at the outer layer of the cytoplasm. In the lower layers, marked inflammation was seen in the papillary bodies, which were narrowed and obliterated. The blood-vessels were surrounded by numerous polymorphonuclear leucocytes and epithelial cells. The superficial layer of thickened epidermis showed extensive necrotic changes before vesicle formation was recognisable. The vesicle, when formed, occupied the top of the hypertrophied Malpighian layer. Balloon and reticular degeneration were seen, as in small-pox, but in alastrim the former was scanty and was found in the upper layers of the stratum germinativum as well. The details of reticular degeneration were identical with those described in variola, but in alastrim it was striking to observe the normal structure of the cells making up the bottom and sides of the vesicle.

The most typical feature, however, was the presence of giant epithelial cells like those of herpes zoster and varicella. This stage gradually passed to that of pustulation, the superficial part of the vesicle being filled with fluid and the lowest part packed with polymorphonuclear leucocytes. Malpighian cells underwent extensive necrosis, and the bottom of the pustule was composed only of leucocytes, fibrin, and connective tissue, but the destruction seemed to be less wide than in small-pox. Inflammatory changes in the cutis vera were marked. Intranuclear inclusions were exceedingly rare in the human material. It was thus possible to diagnose alastrim from small-pox by the histological changes present.

In the subsequent discussion Dr. J. D. ROLLESTON said that the lecture emphasised the scarcity of present information on the pathology of alastrim, and expressed a heterodox view which would give the orthodox furiously to think.—Dr. RUSSELL AMES recalled his serological work on mild small-pox in England, and said it had given no cause for differentiating small-pox from the mild English form. Work similar to that of Prof. Torres should be done on the mild form in this and other countries.—Dr. R. P. GARROW considered that alastrim was not now a tropical disease at all. The distinction made by the lecturer corresponded to the views which some English workers had formed on clinical, epidemiological, statistical, and immunological grounds.—Dr. E. W. GOODALL said that he had distinguished alastrim from small-pox and chicken-pox on clinical grounds. The immunological work had, however, persuaded him that alastrim was merely a variety of small-pox. The work of Prof. Torres made diagnosis easier but had not convinced him that it was a distinct disease. A crucial test would be whether, in an outbreak of the old classical small-pox, one disease protected from the other.

SECTION OF MEDICINE

At a meeting of this section held on Nov. 26th the chair was taken by Sir CHARLTON BRISCOE, the president, and a discussion on the

Causes and Treatment of Obesity

was opened by Sir EDMUND SPRIGGS. The cause, he said, was that the energy in the food had habitually been greater than that spent by the body. Reasonable plumpness might be good, but too much fat did harm, restricting healthy movement, infiltrating important tissues, and making a man or woman less capable. The importance of endogenous factors, lessening expenditure, was obvious; exogenous obesity was due to eating more than others of similar build—increasing income. A low sugar-tolerance curve indicated a considerable endogenous factor. The basal metabolic rate was raised in obesity more often than might be expected. The body was capable of dealing with a wide variation of intake while keeping weight constant. It changed gear silently, and a diet far below that of normal maintenance was necessary to bring about rapid loss of weight. Once a start was made in either direction there was a tendency to continue in the same direction.

The treatment fell into two parts: reduction of food and increase in output of energy. Both measures were carried out simultaneously. Income could be reduced by fasting: the man fasted but his tissues did not. A rapid reduction produced by fasting was not likely to be permanent. It was better to supply the basal needs with a reduction of calories. The basis of the diet was meat and vegetables, but

almost any food could be taken in small quantities. The patient must be made to realise that the total caloric value was what counted. No fixed or published diet could be the most suitable for any individual; the régime must be varied continually. (Sir Edmund Spriggs showed tables illustrating variety in diets of various caloric values.) On a milk diet people were apt to complain of feeling weak, but 4 oz. every two hours eight times a day gave a fairly balanced diet of 600-700 calories. An orange day a week was useful, especially if appetite failed; six large oranges gave 370 calories. Single fruit cures continued for long, however, were starvation cures. Water could be taken freely if food was weighed, but drinking during the meal led to greater consumption of food. Beer, spirits, and wine had considerable food value and must be calculated in a diet. For malaise or headache, a glucose lozenge four times a day between meals was useful.

Most of the energy output went in keeping people warm, and the more nearly spherical a figure was the smaller was the surface available for heat loss compared with the weight. Fat people needed less food than thin. The energy expenditure for muscular work was not great compared with the intake, but exercise was nevertheless a valuable means of losing weight, especially if combined with loss of heat from sweating. The loss from electric light or Turkish baths was apt to be temporary because it consisted largely of water, which was replaced at the next drink. Riding was good but had to be strenuous to be compared with walking fast in cool air. Massage and the Bergonié chair improved the local circulation in people unable to take exercise. Hunger on a reducing diet only lasted a few days and was not enough to make the patient unhappy. Headache and malaise were unusual and were relieved by carbohydrate or a meal. A full reduction régime was not compatible with a busy life, and harm might come—particularly through loss of resistance to infections—to an energetic woman trying to fulfil her engagements on a low diet. Thyroid was the most useful drug. Most people felt better at once, and lost health might be restored. For a successful rapid reduction special cooking, variety of food, individual taste, and medical supervision were needed; it should be for the patient a whole-time task. For a slow reduction there was no need for fuss or special cooking; the problem was one of omission of unsuitable foods, especially restriction of carbohydrate.

Dr. H. GARDINER-HILL said that the obese patient could not fail to lose weight if he starved, but he had great difficulty in controlling his weight on what seemed an average diet. If he took even a little food, he at once stored it and put on weight. In some cases obesity could be traced to alcohol or residence in a hot climate—perhaps owing to a lowered setting of the heat-regulating apparatus. A hereditary tendency was found in 70-75 per cent. Many patients showed a minor degree of endocrinopathy. The regulatory mechanism depended on appetite and impulse to activity and in the obese it was disturbed, but there was also an extraordinary avidity of the tissues for food, salt, and water, without which abnormalities of the regulatory mechanism would perhaps be unable to cause obesity. This excessive storage mechanism was probably due to abnormality on the anabolic side. Obesity was not invariable in any of the endocrinopathies in which it often appeared—except perhaps in Cushing's syndrome. The basal metabolism and sugar tolerance might be low, normal, or high. Insulin might play a part in the storage mechanism; diabetics, and especially children, could

be fattened on insulin with high carbohydrate diet. Obesity was associated with water-salt retention, which accompanied thyroid deficiency, while the opposite condition was found in Addison's disease. Storage powers undoubtedly depended on endocrine influences, but little was known of their mechanism.

Dr. DONALD HUNTER said that the clinical picture of basophilism had been shown at autopsy in certain cases to correspond to that of carcinoma of the thymus or adrenal cortex, the pituitary in such cases being macroscopically normal. It had been shown this year by Crooke that the only change common to all such cases was the hyaline change in the basophil cells. In the last nine years 2447 cases had been referred to the dietetic department of the London Hospital for gross overweight. Only 682 had attended long enough to get any benefit; 92 per cent. had been women and 262 had had simple obesity without illness. Of those who came regularly, 93 per cent. were obedient and lost weight, some 12 tons of fat having been removed from East End ladies in the nine years. The first part of the problem was to convince the patient that weight could be reduced by dietetic means only, without drugs and without malaise or interference with normal life. The loss aimed at should not exceed 2 lb. a week, and the average diet had 1100-1200 calories. The human body obeyed the law of conservation of energy; whatever the factors producing obesity, any individual on an inadequate diet would lose weight. It was important to realise that the dietetic treatment of obesity was a practical proposition; the only real difficulty was psychological.

Dr. E. P. POULTON described a case where a bed-ridden patient had been reduced from 13 to 10 stone and had maintained this weight for a year on a diet of 600 calories. It was possible to live on one or two grammes of nitrogen a day, but for practical purposes it was difficult to get protein below 30 g. a day; this was a reasonable amount to live on. Protein, he thought, was used as food, and had no specific dynamic action.

Dr. S. LEVY SIMPSON wished he could regard obesity as so simple a question. He thought there was no such thing as simple exogenous obesity—i.e., one with no underlying endocrine factor. It was like saying that in diabetes insipidus a patient passed lots of urine because he drank lots of water. Pathological appetite was a very real entity; pituitary obese types often said that their hunger for sweet things amounted to craving at times—often just before menstruation. Somnolence was associated with the less gross forms of obesity, and there might be a tendency for patients to spare themselves short of actual sleep. Physically the law of conservation of energy must hold, but there was more in the problem than that. Two people eating the same amount and doing the same work might be of very different weight, and this fact required explanation, as did the familial and racial features.

Dr. LEONARD FINDLAY said that his experience with East End children had led him to diametrically opposite opinions from those of Dr. Hunter. People varied tremendously in their response, and excessive diet was not the main factor in obesity. Everyone every day took more nourishment than he required, but many did not get fat. The reason was something to do with metabolism. Children on diet get irritable and usually it was better to leave them alone if they were otherwise well. A study of the creatinine output had shown that this was proportional to the increase in weight in most cases; it was bound to influence the basal metabolic rate.

Dr. F. PARKES WEBER thought that the difficulty arose when obese people wanted to eat more; there came the psychological problems and crux of the whole matter. It was almost against human nature, for fat people to submit to relative starvation. The way of the future, he thought, was some method of reducing appetite without doing harm or diminishing the joy of life.

Dr. H. W. HALES viewed obesity as a symptom of oxidation deficiency produced by tissue and intestinal poisons. Prolonged fasting cleared up a number of pathological conditions. After long fasting voracious appetite did not return, and patients did not regain weight. The integrity of the skin, liver, and intestinal mucosa were essential for fat oxidation. Treatment should include a study of that put into and excreted from the alimentary tract. There were certain toxic principles in food, especially meat, of which avenin was an important example; these toxic bodies became fixed in the tissues and could only be eliminated by very low diets. Hunger was analogous to the withdrawal symptoms felt by drug addicts; food was in many ways a dangerous drug. Colonic detoxication was essential, and pyretic baths were of the greatest importance.

Sir EDMUND SPRIGGS and Dr. HUNTER replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND

A MEETING of the section of medicine was held on Nov. 8th, with Dr. V. M. SYNGE, the president, in the chair.

Münchmeyer's Disease

Dr. R. W. SHAW showed a patient who had been previously brought before the section, in March, 1934, with a tentative diagnosis of pseudohypertrophic muscular dystrophy.

She was now 8 years old. In September, 1934, she developed a severe cold and was feverish for a week. In November, for the first time, Dr. Shaw noticed numerous small soft nodules in the flexor aspects of the elbows and knees and in the tendons of the biceps and hamstrings, and also in the tendons of the pectorals. Otherwise the child was in fair health, but she was very small, her height being 3 ft. 6 in., and her weight 3 st. 3 lb.

In February of this year she developed diphtheria and scarlatina, and was sent to Cork-street Fever Hospital where she remained till May. The long period in bed had greatly weakened her power of locomotion, and about a week after leaving hospital she was brought to Dr. Shaw with what he at first took to be an abscess on the inner aspect of the left knee. There was considerable inflammation and induration of the area. On further examination the abscess was found to be one of the previously noted nodules which had apparently broken down and was discharging a cheesy material. By the end of May this condition had almost healed but the nodules were much harder and more numerous. On May 29th, after a minor fall, the child sustained a fracture of the right femur just above the condyle, and was admitted to hospital where she remained until early in August. At first there was considerable difficulty in walking. At present she was able to walk fairly well, but had limited movements of limbs. She had two discharging sinuses in the left knee. Her face was expressionless, and there were red markings on various parts of her body. Her height was now 3 ft. 6 in. and her weight 2 st. 11 lb. She was very intelligent. She ate and slept well. Nodules could be seen and felt. There were no knee-jerks. The urine was normal.

Dr. Shaw thought that the case was one of Münchmeyer's disease (diffuse progressive ossifying poliomyelitis), although the patient presented but few

of the classical features. Only about 200 cases had been published and the aetiology of the disease was obscure, but it did not seem to have any connexion with an upset of calcium metabolism. The onset was usually before the age of five; it might develop in the course of some infectious disease, or calcification and ossification might occur in small hæmatomata caused by injury—e.g., by a hypodermic needle. In the present case it developed after dysentery, and the first swelling was noticed after a hæmatoma. The effects produced might be of two kinds: (1) total petrification of the muscles which preserved their form, and (2) irregular ossification producing osteogenic exostoses; often but not always, the skin over the osteomas was normal. The disease progressed only very slowly to the stage described by Virchow as "l'homme pétrifié." The condition was chronic, but it progressed in bursts followed by long periods of inactivity. Respiratory embarrassment and difficulty in deglutition might eventually lead to intercurrent infection.

Dr. DOROTHY PRICE thought there was now no doubt about the diagnosis of Münchmeyer's disease in this case. The speed with which the condition had come on was very remarkable. All the calcium in the body appeared to be going into the muscles. The expectation of life in these cases seemed to be long.—Dr. W. G. HARVEY said it appeared to him that the great majority of the tumours were very superficial, and asked if Dr. Shaw had located any of them, and, if so, how deep they were.—Dr. E. T. FREEMAN asked what the nodules were composed of.—Dr. E. HARVEY asked if any investigations had been done on the parathyroids in this case.—Dr. T. O. GRAHAM referred to the case of a "stone man" who had been in Sir Patrick Dun's Hospital when he was a student. He had been kept in hospital for two years, and after that went to a hospital in Belfast. A diagnosis of myositis ossificans had been made, but there were no stony deposits in the skin.—Dr. C. J. MURPHY said that myositis ossificans was traumatic in origin. Dr. Shaw's case had come to light after trauma. He wondered if there was any relation between trauma and the origin of Münchmeyer's disease.

Dr. Shaw, in replying, said that the tumours in the gluteal muscles were pretty deeply in. He had not as yet examined the nodules chemically. No investigation had been made into the function of the parathyroids. He did not think that trauma had played any part in the appearance of the nodules. The child had had an accident, but before the accident he had noticed the nodules.

Pellagra

Dr. E. T. FREEMAN showed a case of pellagra with much pigmentation on the face. The condition got worse in the summer, and almost faded away in the winter. The patient had been given a small dose of ultra-violet light to see if she was sensitive, and her skin had reacted strongly. The blood count was normal, and the urine was normal. She complained of a skin rash, bodily fatigue, pains, and a feeling of constant tiredness. She had not eaten maize since she was a child, and then had only taken it in very small quantities. For the last five years she had had quite an ordinary diet containing plenty of vitamins.

The PRESIDENT said that before 1927 only two cases of the disease had been reported in Ireland, and Dr. M. DRUMMOND said that in the last ten years he had seen only four cases.

REVIEWS AND NOTICES OF BOOKS

Sir Donald MacAlister of Tarbert

By His Wife. London: Macmillan and Co., Ltd. 1935. Pp. 392. 12s. 6d.

Sir Donald MacAlister's extraordinarily brilliant academic career, and his success as administrator in two great and completely different posts, is set out here in sober language by his wife. It is a record of performances and happenings, and although there is no criticism of the subject of the biography—which could not possibly be expected—still the book is neither a bare record of successes nor an adulatory stream. In presenting the portrait of a great personality opportunity has been taken to shed considerable light on important problems in education—general and medical.

Donald MacAlister was the descendant of an old and erst wealthy Scottish family, the MacAlisters of Tarbert; their property being eaten up by a contiguous duke, the head of the family some hundred years or more ago was landless and poor, a crofter and fisherman. He had a large family and his eldest son, born in a farm at Tarbert, was a bookish boy and set out to seek his fortune in Glasgow. He made good as manager of more than one well-known publishing firm and went to Liverpool in that capacity, where his eldest son, eventually to become Sir Donald MacAlister of Tarbert, began his serious education. This culminated, after a series of prizes, bursaries, and exhibitions which made the scholar self-supporting from childhood, in the senior wranglership at Cambridge in 1877. He then pursued an original ideal by qualifying in medicine; this he did from St. Bartholomew's Hospital medical school and returned to Cambridge to become fellow and tutor of his old college, St. John's, assistant to Sir George Paget, the regius professor of physic, and physician to Addenbrooke's. Early elected to the fellowship of the Royal College of Physicians of London, he made his scientific mark by an excellent translation of Ziegler's *Pathological Anatomy*, the fruit of post-graduate work at Leipzig under Ludwig, and by his Goulstonian and Croonian lectures. His great public career began when in 1889 he succeeded the famous Humphry as representative of Cambridge University on the General Medical Council.

An appendix to the biography dealing with MacAlister's work on the G.M.C. has been written by his successor in the presidential chair, Sir Norman Walker. Sir Norman testifies, with simplicity and detail, to what all men know, that under MacAlister's long guidance the Council grew steadily in influence; its finances became stable and its great function, that of standardising medical training and maintaining due ethical principles, both in the public interest, was made apparent by his actions no less than by his careful and practical half-yearly addresses.

In 1907 MacAlister was appointed principal of the University of Glasgow, and here again the biographer has looked outside for proof of his varied accomplishment, for Sir Robert Rait, the present principal, has supplied the story in a full appendix. MacAlister's learning, his devotion to duty, and sympathetic appreciation of other men's difficulties alike made him a model principal and gained for him the exceptional honour of being appointed chancellor of his university.

From this record there emerges the picture of a remarkably gifted man, and it is not surprising

that at his death, some two years ago, the writers of the obituary notices should have, almost with one accord, reflected that whatever professional career he had adopted he would inevitably have become its head. Scholar, linguist, organiser, and man of affairs, along each of these lines he was equally pre-eminent. Hence it is a charming feature of Lady MacAlister's account that we should learn from her the religious simplicity of his private life. Men with such intellectual attributes as MacAlister are apt to be a little terrible to their fellows, especially when their qualities are hall-marked by an almost incredible number of State and academic distinctions; MacAlister's learning and force of character, we can see, never made him other than kind, sympathetic, and helpful. For the intimate picture of him which Lady MacAlister is able to draw, all readers will be grateful.

Hormone des Ovariums und des Hypophysenvorderlappens

Second enlarged edition. By Dr. BERNHARD ZONDEK, Professor an der Hebräischen Universität, Jerusalem; Direktor der Gynäkologisch-Obstetrischen Klinik des Rothschild-Hadassah-Hospitals, Jerusalem. Vienna: Julius Springer. 1935. Pp. 638. R.M.58.

THIS work on the hormones of the ovary and of the anterior lobe of the pituitary gland has been considerably enlarged and brought up to date, and is now so elaborate that it almost defies the reviewer. It belongs to that type of German work which includes a reference to practically every paper that has been written on the subject, with the result that though it is of the utmost value to research workers, the general student will find it far too complicated and lacking in critical judgment. Research workers will find one section disappointing—the chemical section. The reference to the chemistry of the sex hormones is too brief to be of much use, and many important papers on prolactin are ignored. In a work of this size the reader is entitled to expect either an adequate summary of the chemical aspect of the problem, or at least a complete series of references to the more important papers.

Radium Treatment

Of Skin Diseases, New Growths, Diseases of the Eyes and Tonsils. By FRANCIS H. WILLIAMS, M.D. Harv., Senior Physician, Boston City Hospital. Boston, Mass.: The Stratford Company. 1935. Pp. 118. \$2.00.

THIS little book gives an interesting account of 30 years' experience in the use of radium, and particularly of the early efforts to find a scientific method of measuring the dose absorbed in the tissues. A fluorometer is described together with the author's arrangement for making his standard comparisons with rays which have passed through varying thicknesses of water before they reach the fluorescent screen, a method which appears to be sound when mixed beta and gamma radiation from lightly screened preparations is to be measured.

Three main types of lesion are dealt with: lesions of the skin, of the eye, and of the tonsil. The cases of cancer of the skin are similar to those usually described but the interest lies in the fact that 17 cases

of rodent ulcer were reported in 1908 and 181 cases of skin cancer, of which 154 healed in 1913, at a time when the therapeutic uses of radium were little understood. For the eye ingenious instruments are described, and the author makes some surprising claims for his methods. Corneal opacities due to ulcer are said to clear up, anterior capsular cataract to disappear, and in one case it is claimed that retinitis pigmentosa was arrested. For infected tonsils treatment with relatively large quantities of radium, 55 mg. filtered with 0.6 mm. of aluminium for ten minutes, applied direct to the tonsil, is said to be most effective. It seems quite possible that this direct application may be helpful in causing shrinkage of the inflamed mucous membrane and so allowing the escape of the retained septic secretions; but the claim that the tonsil is favourably affected by radium held over the skin of the neck in the region of the tonsil for 5 to 15 minutes will be regarded with scepticism by most radiologists.

Introduction to Vertebrate Embryology

Third edition. By WALDO SHUMWAY, Ph.D., Professor of Zoology, University of Illinois. New York: John Wiley and Sons; London: Chapman and Hall Ltd. 1935. Pp. 390. 20s.

Most text-books of vertebrate embryology deal exclusively with morphology. The existence of experimental embryology is rarely mentioned except to the advanced student. The time has now come, however, when a reasonable account can be given, even in text-books, of the forces at work during development. Prof. Shumway deserves congratulation on the way in which he has combined the two aspects of the subject in this third edition of his work. Two admirable chapters are provided on the theory of the gene and on experimental embryology; these should give the student a good general idea of what is known of the action of hereditary and environmental factors upon the course of development. The second half of the book deals in a clear and concise manner with the elements of organogeny, the anatomy of some embryos, and with embryological technique. Useful bibliographies are supplied at the end of each chapter.

How Animals Develop

By C. H. WADDINGTON, M.A., Fellow of Christ's College, Cambridge. London: George Allen and Unwin Ltd. 1935. Pp. 128. 3s. 6d.

This is the first attempt that has been made in the English language to give a popular but comprehensive survey of the recently developed science of experimental embryology. The investigator is here faced with fundamental problems, and it is reasonable to expect that research in this field will eventually lead to results of extreme importance to the biological sciences in general. Mr. Waddington's book makes very good reading and gives a clear, though necessarily simplified, account of his subject. He leads us in a logical manner through the necessary morphological introduction to the fascinating experimental work of Spemann, the Nobel prize winner, and his followers on the "organiser." Mention is also made of the influence of hormones, of function, and of other factors upon the course of development. We are left confronted with the as yet completely unsolved problem of the individuation field or the causes underlying

the "pattern" of an organism. For the student this book will provide a stimulating introduction. It is more difficult to say whether the intelligent layman, to whom the book is also addressed, could form a sufficiently clear picture of the normal course of development to enable him to grasp the full significance of these problems. Failure in this respect could hardly be laid at the door of the author, for developmental anatomy is extraordinarily difficult to visualise without some practical acquaintance with embryos.

1934 Year Books

1. *General Therapeutics*. Edited by BERNARD FANTUS, M.S., M.D., Professor of Materia Medica, Pharmacology, and Therapeutics, University of Illinois College of Medicine. Chicago: The Year Book Publishers, Inc.; London: H. K. Lewis and Co., Ltd. 1935. Pp. 462. 9s. 6d.

2. *Neurology, Psychiatry, and Endocrinology*. Edited by HANS H. REESE, M.D. (Neurology), Professor of Neurology and Psychiatry, University of Wisconsin Medical School; HARRY A. PASKIND, M.D. (Psychiatry), Assistant Professor of Nervous and Mental Diseases, Northwestern University Medical School; and ELMER L. SEVRINGHAUS, M.D. (Endocrinology), Associate Professor of Medicine, University of Wisconsin Medical School. Same publishers. 1935. Pp. 782. 12s. 6d.

1. These year books are, as is now well known, small, compact, and well printed. This one contains several hundred summaries of newly described methods of treatment, covering general medicine, minor surgery, anaesthesia, toxicology, and physical (including radiation) therapy. They are attractively written, and sometimes illustrated, and an occasional editorial comment is supplied in modest small print. American literature provides the source for the great majority of the articles; English and German for most of the rest. The editor makes no claim to comprehensiveness, but for all whose fields it touches the book is worth looking through. It is sure to yield something of interest or of value, and to yield it quickly.

2. This member of the series was edited until recently by Dr. Peter Bassoe. Obligated for reasons of health to give up the task, he has cast his mantle, in triplicate, on new editors, and the book now has three independent sections. It is packed full of meat, partly predigested. The papers abstracted include surveys and short reviews as well as original contributions in the strict sense, and the abstracts, usually clear and well written, are full enough to let the reader know whether or not he wishes to study the papers themselves. Prof. Sevringhaus introduces his section with a twelve-page outline of "systematic endocrinology"—a brief undocumented statement of current ideas of the inter-relationships of the glands—and confines his abstracts to papers on clinical endocrinology; even so, they occupy one-third of the volume. Guides are almost indispensable in the maze of medical literature; this is a competent one.

NOTTINGHAM GENERAL HOSPITAL.—The foundation-stone of the new pay-bed wing of this hospital was laid on Nov. 13th. The sum of £60,000 necessary to complete the project is assured and the 23 wards are being equipped and furnished by Sir Julien Cahn. The hospital will be opened free of debt and will be self-sustaining.

NEW INVENTIONS

HENRY AND JOUVELET'S PUMP
FOR BLOOD TRANSFUSION AND OTHER PURPOSES

We have had an opportunity of testing this ingenious machine which is already in extensive use on the Continent. In principle it consists of a metal cup in which a vertical roller rotates about a central spindle (see Fig. 1). A loop of sterile rubber tube, which is to convey air, blood, or other fluid, is inserted between the roller and the sides of the cup, and when the central spindle is turned the roller compresses the tube, squeezing its contents along at a given speed. Two models are made, worked respectively by hand (Fig. 1) and by an electric motor (Fig. 2). A cyclometer denotes the amount of fluid delivered, and this amount can be varied from 0.15 to 300 c.cm. per minute by altering the speed of rotation. Reverse and forward movements are provided so that suction or propulsion can be obtained. Pressure gauges give warning of any obstruction to the flow in the tube.

Although the machine was primarily designed for direct transfusion (which can be performed in one operation), we have used it successfully for indirect transfusion of blood or saline, continuous drip transfusions of these fluids, infiltration of local anaesthesia, and other purposes. The method of using is as follows.

1. *Transfusion.*—All the preparation necessary is to sterilise a flask or jug, two fine needles, and the two pieces of rubber tubing provided. This ease of preparation is very valuable when working in a private house or nursing-home. The tube is fitted into the machine and a fine needle attached to one end. Citrate solution (3.8 per cent.) is sucked through the needle and tube and collected in the sterile flask into which the other end of the tube dips. The needle is then inserted into the donor's vein and the required amount of blood withdrawn, to be mixed with the citrate by shaking. (Owing to the very

powerful action of the pump, we have found it possible to use quite fine needles for the donors, and this is much appreciated by them.) The second tube is now fitted to the machine and the blood pumped from the flask into the patient's vein at any desired rate. Infusion of saline and other fluids is very easily carried out by a similar technique, the fluid being contained in a flask clamped to an upright on the machine.

Essential parts of the hand-worked pump.

2. *Continuous drip transfusion or infusion.*—We have found the motor-driven model to possess very definite advantages over the gravity methods commonly used for this procedure. The flow is maintained without intermission for as long as desired, and even when the fluid is dripping slowly from the needle it has a considerable pressure behind it, and this appears to prevent the clotting which is the main difficulty of continuous intravenous injections. Our method is to place the citrated blood or the saline in a flask surrounded by a Gamgee jacket, and to pump it into the patient by means of a glass cannula tied into the saphenous or other vein.

The blood is continuously mixed by passing through it bubbles of filtered oxygen, as suggested by H. L. Marriott and A. Kekwick (THE LANCET, 1935, i., 977). We have thought it advisable to add a float device which automatically cuts out the motor should the flask not be replenished at the proper time. By this means all possibility of injecting air into the vein is eliminated. An automatic cut-out will be available shortly to control definite quantities of fluid being given, or to cut out should the flask not be replenished at the proper time.

The electric pump. Fluid is flowing from a burette and is being pumped through the rubber tube.

3. *Infiltration of local anaesthetics.*—We have used both the motor and hand models for infiltrating the abdominal wall and the neck. The advantage is that the surgeon can create a wide and deep field of anaesthesia with a solution delivered at a regulated pressure and rate of flow.

The apparatus is capable of many other uses, three of which are aspiration of effusions, establishment of artificial pneumothorax, and suction during operations.

Our short experience, based on 22 cases, has shown us that the apparatus possesses certain definite advantages in transfusion. The fact that the pump, whether driven by hand or motor, does not require sterilisation rules out that complication associated with subjection of machinery to extremes of temperature or contact with antiseptic solutions. The pump action being reversible permits anticoagulant fluid and donor's blood to be drawn through the tube into the collecting flask, and then propelled into the recipient through an airtight system. To make sure that the recipient's vein has been entered we insert a glass connexion into the tube close to the needle and fill the tube with anticoagulant fluid. As soon as the vein has been punctured the pump is put in reverse and blood is seen in the glass connexion; all is now well and the forward speed is applied. Collection of the donor's blood by suction leads to some frothing in the flask. Using fine needles (Record Serum No. 1) and a tourniquet applied to the arm of the donor at 80 mm. Hg we have had no trouble with clotting, nor collapse of the vein. Blood can be injected into the recipient at 40 c.cm. per minute without giving rise to pressure changes. In continuous transfusion we have been able to avoid venous thrombosis, but the noise of the motor is an objection, which the makers are taking steps to overcome. In our experience the machine has proved entirely reliable. It is obtainable in this country through Messrs. Jourdan and Black, 24, Pall Mall, S.W.1.

THE LANCET

LONDON: SATURDAY, NOVEMBER 30, 1935

THE EXTINCTION OF VENEREAL DISEASES

At the International Congress of Dermatology and Syphilology held this autumn in Budapest it was "accepted as a fact that syphilis and gonorrhoea could be made extinct throughout the world within a single year if all who suffer from them would have themselves fully treated." We are quoting the actual words¹ of our Budapest correspondent, who went on to say that as a corollary to this principle the Congress "proposed the application of legal penalties and the State control of treatment, together with the regulation of prostitution." Now there is no doubt that the organisms of syphilis and gonorrhoea are both easily destroyed under the ordinary conditions of exposure to heat, dryness, light, and air; and it is only as the result of extreme adaptation to the special environment in which they live that they have managed to exist and flourish for so long. There is also no doubt that in the arsenicals we have a very potent weapon at hand for making patients non-contagious in the early and communicable stages of syphilis; and, although unfortunately there is no similar weapon at present available for the treatment of gonorrhoea, yet we believe that with reasonable care we can guarantee a clinical, bacteriological, and serological cure in all but a minute proportion of cases inside a year. It therefore seems not unreasonable to suppose that, if everyone infected were promptly and adequately treated, these age-old curses of mankind would speedily be eradicated. Theoretically this is true in a world governed by logic and reason; but unfortunately we live in one that is ruled by emotion, love and hatred, illogical likes and dislikes; and the moment we are up against any of the problems associated with sex this becomes manifest to the most casual observer. Practically then the administrative, technical, and social difficulties in the way of carrying out anything like a world-wide campaign of diagnosis, notification, treatment, and penalties for neglect of treatment of venereal disease are so great that we may consider the pronouncement of the Congress in the light of a dramatic gesture intended to draw attention to the fact that, given proper facilities, we have the weapons in our hands to control and finally eradicate these diseases as soon as the conscience of the nations is sufficiently awake to allow us to do so without let or hindrance.

None the less, it is worth while to pause, take stock, and consider what suggestions the Congress has made, for in this way we may clarify our own

ideas of what is possible, and what history tells us is repugnant to the British mind. Let us first consider the question of the regulation of prostitution. The continental mind has always been favourable to some kind of police control of this evil, generally taking the form of the registration, segregation, and periodic medical examination of all women who habitually (or even occasionally) sell their bodies for gain. As a necessary consequence such women if found diseased are sent into hospital, whether they will or no, and are kept there until pronounced cured. Paris, Berlin, and Vienna carry on systems intended thus to control prostitution, and so incidentally minimise the spread of venereal disease. It is a comment on the success of these endeavours that it is precisely to these places that students of venereology flock because of the abundance of the material. In England, control was attempted in certain garrison towns such as Aldershot, Chatham, and Portsmouth under the Contagious Diseases Acts. The results were so ambiguous, and the outcry against the regulations so great, that the Acts were rescinded in 1886, and it is unlikely that any administrative body in this country would now urge their re-enactment. We have it on the authority of FLEXNER that it is the considered opinion of all unbiased observers that regulation of prostitution in the past "has increased, not diminished, the volume of venereal diseases." Advocates of regulation, whilst admitting this, maintain that such a result is largely due to the defective medical treatment given in the past. No doubt that is part of the truth. But there are, in addition, two great human factors which these enthusiasts overlook, factors which are still operative and likely to remain so. The first is that the clandestine prostitutes outnumber the registered ones in every large continental city, it may be by as much as eight to one, so that, even admitting that all registered prostitutes could be kept free from disease, there still would remain this great silent reservoir of untreated or ignored sources of contagion. The second cause for failure is that the male partner has never been segregated. It is possible to shut up the harlot. She is a social outcast. She is a parasite on society. She serves no useful object. But to imprison the male partner is to disturb violently all social and business life. How would the Congress attempt to overcome this enormous handicap to success? Think of the portentous upheaval it would produce. Think of the campaign of bribery, corruption, espionage, blackmail, that would inevitably follow any real attempt compulsorily to treat infected males. Yet if one cannot treat both sides alike how can one hope to effect the proposed result?

State control of treatment is another plank in the programme of the Congress. By this is probably meant a system of free treatment at clinics, subsidised by the State, and open to all venereal patients without consideration of rank or position. This is a more modern line of thought. Instead of, or in addition to, attempting to protect the public by treating diseased prostitutes under

¹ THE LANCET, Nov. 9th, p. 1078.

police supervision, it is suggested that all persons suffering from venereal disease should be under the care of the public health authorities. Obviously there is much to be said in favour of this. For many years it has been tried in the Scandinavian countries, where it met with such success that it was introduced into this country towards the end of the late war. Here the success obtained has not been dramatic, but it has been continuous. By careful newspaper propaganda, by assuring the patients that privacy of treatment is available and that no information will be given of their condition to unauthorised persons, by explanatory pamphlets setting out the dangers of the diseases and the length of time required for treatment, by "continuation" cards and a judicious "follow-up" of those who have stopped treatment before cure, it has been possible to build up machinery which in time, it is believed, will get these diseases under control. No general attempt has been made by interested bodies in this country to introduce penal regulations for absconders—that is those who neglect to continue treatment until cured. Legislation of this nature has been introduced in some of our dominions and colonies, but it has been found that doctors object to being turned into detectives and fail to notify cases, with the result that the laws become a dead letter. Experience shows the unwisdom of legislating in front of public opinion; and public opinion is against doctors giving away their patients' secrets. The moment minatory regulations are introduced to round up absconders from treatment for any disease to which a moral obloquy is attached, at that moment the disease goes underground, and patients no longer come forward willingly. The mere suggestion that neglect to keep up treatment may expose the victim to shame is enough to inhibit desire for such treatment, and thus to frustrate the good intention of the inquisitor intent on saving the sufferer from himself. That is why, when two corporations in Scotland recently tried to obtain Parliamentary sanction to introduce some mild penal clauses for those who ceased to attend, the attempt failed.

Final success can be attained only by educating the public to the dangers of venereal disease, by stimulating the conscience of the community so that the dual standard of morals as between man and woman is no longer accepted as inevitable, and by making facilities for treatment so easily obtainable that there can be no excuse for refusing. In this way we may hope that we shall be able eventually to eradicate venereal disease from our midst, an end which has been the devout wish of every sanitarian since the time of MOSES.

GASTROSCOPY

Two notes appearing in our columns a couple of years ago have indirectly borne fruit in the form of Mr. HAROLD EDWARDS'S contribution to our last issue. He must be one of the first, if not the first, in this country to make systematic use of the flexible gastroscope. He approached it with a certain reserve, aware of the risk that a pretty

piece of mechanism may awake more enthusiasm than its usefulness justifies, but he concludes that the instrument has already earned a place in the management of cases of gastric disorder. It can sometimes contribute to the diagnosis of gastric ulcer, when the radiologist is left in doubt; it can sometimes indicate whether a suspicious ulcer is simple or malignant; and it can often throw useful light on the state of the mucous membrane round the stoma of a gastro-enterostomy.

A pretty piece of mechanism it certainly is, and the merely medical mind can only marvel at the fact that one can see quite comfortably through it whether it lies bent or straight. The special arrangement of lenses within a flexible metal spiral, by which this is made possible, is the discovery of WOLF of Berlin, whose firm for many years has spent skill, time, and money on the technical problems involved. Its reward, financially speaking, seems to be at hand, for the instrument has been in regular use for some years in many of the larger continental clinics, and is attracting attention now in this country and in America. The later models differ from that figured in THE LANCET of Oct. 14th, 1933, in having a brighter light and a narrower rigid part (7.5 mm. diam.), but these are minor improvements; there is no word yet of two major advances that gastroscopists would warmly welcome. One of these is a device for altering the direction in which the instrument "looks," which is normally at right angles to its long axis; flexible gastroscopes can also be made to "look" either directly forward, or laterally and backward, the field of vision in every case subtending an angle of about 60°, but the three possibilities have not yet been combined in one instrument. If that combination were achieved, almost the whole of the gastric mucosa would come within the range of vision, and negative gastroscopic findings in cases of suspected ulcer or carcinoma would have considerable value. The other desirable advance is a camera capable of taking photographs through a flexible gastroscope. HENNING^{1,2} has published many photographs of the gastric mucosa, but they have all been taken through a rigid straight gastroscope, an instrument which he and other experts can now manipulate with safety, but which remains too dangerous for general use. The flexible instrument does not transmit quite enough light to give satisfactory photographs; a still brighter light, provided it is not too hot, or a more sensitive film, might solve this problem. Until it is solved the appearances of the gastric mucosa can be discussed only in verbal descriptions or with the help of drawings, both of which involve rather more of the subjective element than is welcome to the scientific mind.

As we have said, however, Mr. EDWARDS finds that the present instrument can give some help in diagnosis and treatment. His point of view is that of a surgeon. Judging by the experience in

¹ Henning, N.: Lehrbuch der Gastroskopie. Leipzig: Johann Ambrosius Bart. 1935.
² Henning, N.: Die Entzündung des Magens. Leipzig: Johann Ambrosius Bart. 1934.

Germany, where the gastroscopist is nearly always a physician, medicine has even more reason than surgery to interest itself in the gastric mucous membrane. The old tradition that the appearance of the tongue indicates the state of the lining of the gastro-intestinal tract can now be tested, so far as the stomach is concerned, by direct observation, a study which MOUTIER has begun in Paris, publishing this month³ an interesting series of paired pictures showing inflammatory conditions in tongue and stomach. In Germany a number of distinctive and easily recognised inflammatory pictures in the gastric mucosa have been described, and are there the basis for the diagnosis of chronic gastritis, which is made in many patients who would in this country receive the label of functional dyspepsia. As yet however no satisfactory correlation has emerged between the presence and nature of these changes and the patient's dyspeptic symptoms. On the other hand correlation between gastroscopic and microscopic appearances is not lacking. Chronic gastritis is important both as a morbid change in itself and in its relation to ulcer, cancer, and the anæmias, and few will question the need for fuller study of its occurrence and its pathogenesis. To all who concern themselves with the investigation of these problems gastroscopy would seem to offer a useful—and it may be, indeed, an indispensable—method of approach.

THE BATTERSEA GENERAL HOSPITAL

ON Nov. 19th Mr. Justice EVE made the orders which eliminate from the name and objects of the Battersea General Hospital the element of antivivisection. The proceedings in the Chancery Division, described more fully on another page, leave the hospital free to minister to the needs of a poor and populous district without any restrictions on the use of remedies obtained by experiments on animals. The court was invited to consider, amongst other evidence, two affidavits which showed the deplorable effect of the restrictions. One, sworn by Mr. JOHN ROBERT LEE, the senior honorary surgeon, declared that the progress of science and advance in medical knowledge had made it impossible to run a general hospital on antivivisection principles as enunciated in the memorandum of association of the Battersea undertaking. In many cases of disease, said Mr. LEE, relief and cure were obtainable only by use of remedies derived from sources which would conflict with those principles. Antitoxin, for instance, was a necessity for diphtheria; for tetanus inoculations a serum derived from horses would be used; other examples were antistreptococcal serum, insulin, and various drugs which were standardised on animals. In Mr. LEE's opinion it was essential, in order to enable the hospital to be conducted on modern scientific lines, that all reference to antivivisection principles should be omitted from the objects and trusts relating to the hospital. A second affidavit, sworn by Lord ERNEST HAMILTON, the chairman of the

board of management, dealt with the financial effect of the restrictions. The King Edward's Hospital Fund for London would give no help so long as the hospital was subjected to conditions which contradicted the greater part of medical opinion. "Moreover, general opinion has been moving against antivivisection since the dates of the trust deeds, and I am satisfied that no sufficient financial assistance can be obtained from the public or from any general appeal or similar method so long as the hospital is restricted as aforesaid." Mr. Justice EVE, in granting the petition of the hospital for the change of name and objects, observed that he personally sympathised with the original objects and principles, but he was satisfied that they were no longer practicable. He thought the diminution in the hospital's income was due in part to the fact that everybody had now to pay so much in taxation that they had little left to give in charity. We may hope that the chairman of the hospital is justified in his belief that the new freedom from restrictions will mean new sources of revenue.

Antivivisection propaganda can be violently provocative. These controversies distract the energies of persons engaged in medical practice and research. Love of animals is a characteristic of our countrymen and countrywomen. Another British trait is the habit of making allowance for impulsive statements induced by warm sympathies and sincere convictions. The old Battersea principles somehow contrived to encourage moral condemnation of medical and surgical treatment elsewhere. The hospital claimed to be a "visible protest against the demoralising practice of performing any experiments upon animals"; the results of those experiments were described as "dangerous, misleading, and opposed to all true progress." These protests and descriptions have been frankly withdrawn; a chapter is closed and a happier chapter opens. The Battersea General Hospital has its work to do; we can all unite in wishing it prosperity.

THE Institute of Hygiene is praying for a supplemental charter which will enable it to merge with the Royal Institute of Public Health. It has been apparent for some time that there is considerable affinity between the activities of the two institutes: their work is educational and has for its object the promotion of hygiene and of public health. Founded in 1886, the Royal Institute of Public Health trains post-graduate medical students for the D.P.H., and also maintains bacteriological and chemical laboratories and undertakes tests and examinations for municipal authorities and medical practitioners. The Institute of Hygiene was founded in 1903 and incorporated by Royal Charter in 1929. Its aims and objects are to promote hygiene in any or all of its branches, but especially personal and domestic hygiene. The councils of both institutes are satisfied that the objects of each body can and will be carried out with greater efficiency and to the greater benefit of the public by an amalgamation. The appropriate meetings of the councils have been held as well as the necessary statutory meetings of the members, and the voting has been unanimously in favour of an amalgamation.

ANNOTATIONS

THE CHILDLESS MARRIAGE

THE problem of the childless marriage has had far more attention in America than in this country, and something of the progress made there may be judged by two papers presented last summer to the American Medical Association. In the first Dr. Brooke Bland and his colleagues¹ write on functional sterility in the female and its clinical investigation. Both in men and in women it is difficult to interpret sterility unless an anatomical abnormality can be found, for we usually have to consider it in the light of the complicated relationships between the glands of internal secretion. The observations recorded in these American papers bear out Meaker's contention² that as a rule the cause of the childless marriage is manifold—and that there is seldom a single determining factor. It is for this reason that Meaker lays emphasis on the necessity of establishing special clinics in which both husband and wife can be submitted to searching examinations not only by gynaecologist and urologist, but also by a biochemist and an expert in endocrinology. Etiologically functional sterility in the female is classified by Bland according to whether it is primarily due to pituitary, ovarian, thyroid, or adrenal dysfunction. Of these, he says, primary deficiency in the anterior pituitary is by far the commonest, and disease of the adrenals the rarest. The account given of the clinical and biochemical examinations on which a diagnosis is based leaves one realising that an enormous amount of work is entailed in the full investigation of a sterile marriage and that such investigation is seldom done thoroughly—in this country at any rate. The question that naturally arises is: how far do these searching examinations lead to practical results? Much progress has been made in disentangling the complicated hormonal reactions on which ovulation, menstruation, and probably spermatogenesis are based, but so far relatively little advance has been achieved in obtaining extracts that can be used to control these phenomena clinically. Nevertheless, the fact that of 150 women examined at Bland, First, and Goldstein's clinic 53 (or 35 per cent.) subsequently became pregnant, is distinctly impressive. Treatment was, of course, by no means confined to the giving of glandular products, and included such therapeutic methods as low-dosage irradiation of the pituitary gland and ovaries, dieting, and instruction about the most probable time for conception. The figures given by Dr. Paul Titus in the second paper,³ on the causes and treatment of sterility, are in harmony with those of the other writers, and the only point at which a critic might quarrel with him is when he says that absolute sterility in the male, due to gonococcal stricture of the urethra or occlusion of the epididymis, is usually curable by comparatively simple plastic operations. In this country blockage of the epididymal canal following a previous attack of epididymitis is usually regarded as incurable, and most urologists have abandoned the operation of vaso-epididymostomy as useless. Yet F. R. Hagner, in a paper read before the Clinical Congress of the American College of Surgeons in 1930, claimed that 60 per cent. of patients suffering from bilateral occlusion were cured by a plastic operation. Such discrepancies between the

results obtained by English and American urologists show that further investigation will be necessary before a true perspective can be found. Indeed, it is an additional argument in favour of the establishment of a clinic in this country comparable to those founded in America by Meaker. Everyone will agree that the barren marriage may be a source of great unhappiness, and that in their desire for a child many couples would be prepared to go to almost any lengths. The problem therefore should have the same attention in this country as it is apparently getting on the other side of the Atlantic.

ASTHMA AND SINUSITIS

WHILE it is generally conceded that asthma is in the nature of an allergic reaction, the exciting cause of the reaction often remains obscure. Dr. Robert A. Cooke and Dr. R. Clark Grove, of New York,¹ find it very commonly in infective disease of the nasal sinuses. In a series of 688 cases of asthma studied consecutively, they say that infection was the sole cause in 34 per cent., and infection combined with sensitisation to pollens, danders, foods, and the like in a further 15 per cent., making a total of 49 per cent. in which infection played an essential part. If children under ten years old are excluded there remain 470 patients; of these about 8 per cent. had a primary pulmonary infection, while in 45 per cent. sinusitis was the important primary cause. If one inquires why, in certain patients, the symptom of asthma is imposed on nasal infections, the only answer is that these persons have an allergic constitution and become sensitised to bacteria or their products. In all the patients in their series who came to operation, the mucous membrane of the sinuses was of a hyperplastic type, and none exhibited the true pyogenic membrane associated with suppurative sinusitis; of 120 cases recently studied, on which operations had been performed, no less than 80 per cent. had nasal polypi. For antral infection the complete Coldwell-Luc operation on the antrum was always adopted, because the intranasal operation was not found to be sufficient; external operation on the frontal sinus was never undertaken, but ethmoidectomy was often performed, and the sphenoidal sinus was opened when necessary, all these operations being as a rule bilateral. Definite improvement of the asthma followed in 70 per cent. of all the cases, and in 86 per cent. of those who received complete surgical treatment. These results were not immediate; indeed increasing proportions of improvement were seen with the passage of time; thus complete or nearly complete cure was noted in 29 per cent. 6–12 months after operation, in 36 per cent. after 1–2 years, and in 51 per cent. of those followed for 2–3½ years. The benefit is ascribed to a gradual elimination of infection in the deep-seated bronchial glands or mucosa.

Cooke and Grove's finding that in nearly half their cases the asthma was caused by nasal sinusitis is so surprising that it will not gain general acceptance without further support. It will be noted that wherever operation was performed the membrane of the sinuses was hyperplastic, and that none showed the true pyogenic membrane associated with suppurative sinusitis. This hyperplastic sinusitis is a somewhat elusive entity, and they give no details of their methods of diagnosis—whether the sinuses are examined by proof puncture and, if so, whether the

¹ Bland, P. B., First, A., and Goldstein, L.: Jour. Amer. Med. Assoc., Oct. 19th, p. 1231.

² Meaker, S. R.: Human Sterility: Causation, Diagnosis, and Treatment. London, 1934.

³ Titus, P.: Jour. Amer. Med. Assoc., Oct. 19th, p. 1237.

¹ Arch. Internal Med., October, 1935, p. 779.

washings are examined bacteriologically or whether they rely wholly or in part on radiological examination. Thickening of the living membrane of the sinuses is often demonstrable by skiagraphy in allergic conditions of the nose, as in hay-fever, and is generally considered a manifestation of the disease rather than a factor in its causation. Again, in 80 per cent. of their operation cases nasal polypi were present, and if these form a part of the series of 470 patients already mentioned it looks as though over 20 per cent. of their asthma patients had polypi, in which case they can hardly represent a true sample of the asthma population. The claim, however, remains that of 120 patients selected for operation, 84 showed definite improvement after operation on the sinuses; and 38 of them afterwards had asthma either rarely or not at all. Such a result cannot be lightly passed over.

PHILOSOPHY OF A PHYSICIST

SOME essays and addresses by one of the most distinguished leaders in modern mathematical physics¹ provide an admirable illustration of the truth that in the right hands nearly all great principles are capable of simple expression. They would have made a more coherent whole if they had been amalgamated and rewritten; but they might well have become less interesting. Running through them are two leading ideas which all may ponder with advantage. Prof. Schrödinger wonders in the first place whether science is as objective as some, generally young, people often think. History is certainly not, for none of us would read it if it had no colour from the interpreter. And he makes out a good case for the conclusion, almost blasphemous at first sight, that much the same applies to the higher physics, which, as he points out, reflect the fashion of thought of their day as well as the general outlook of their apostles. And in the second place he repeatedly reflects on what he calls the amazing discovery of statistical truth—propositions, that is, which are true for whole populations of atoms and not necessarily true for any individual. Hence one may predict the behaviour of populations but not that of individuals. The idea would have been less fresh to him if he had been a biologist; and its transference to the dead world is yet another example of the incorporation of conceptions derived from the live world into the explanations of the exact sciences. There is much edification to be had in contemplating the similarity between the behaviour of animals and the vagaries of a particle in Brownian movement; it is no superficial analogy.

CUSHING'S DISEASE

THOUGH it is only three years since Harvey Cushing published an account of the peculiar disease that bears his name, no less than 66 cases are now on record. These have lately been analysed by Dr. Vratislav Jonás,² and he is able to add to their number 7 others observed in the clinic of Prof. Hynek in Prague. All 7 seem quite typical with the exception of the second. Here the patient was a woman of 28, and the disturbance started with diabetes insipidus: the pituitary gland, examined by serial sections, showed no abnormality in the anterior lobe, but the posterior lobe and pars intermedia were replaced by scar tissue. Autopsy reports are given only for this and for the first case,

in which a basophil adenoma of the anterior lobe was disclosed. It is of interest that the urine was investigated for the presence of a follicle-stimulating substance and the result was positive in two instances only, in females aged 15 and 33 years. Jonás's analysis of published reports shows that three-quarters of the patients have been women. The most constant symptom was a rapidly acquired adiposity, but sexual disorders were found in two-thirds. The most constant physical sign was arterial hypertension (88 per cent.), striae of the skin ranking next with 71 per cent., and obesity of characteristic distribution in about the same proportion. Skeletal decalcification was observed in 40 out of 55 examined cases, and a lowered tolerance for carbohydrate in 35 out of 49. It is noteworthy that an increase in the red blood-cell count was found in only 46 per cent. Sufferers from this disease are particularly liable to die from sepsis, but observation now seems to show that the illness need not necessarily be progressive and fatal; in other words, there are benign forms. Jonás concludes from the histological reports that the pathogenesis is by no means clear, but from the clinical aspect this syndrome is sufficiently defined to merit its acceptance as a disease *sui generis*.

MALIGNANT CELLS IN SPUTUM

CANCER cells are rarely found in the sputum, but that is partly because they are not looked for or recognised when seen. As Hoesslin pointed out long ago in his monograph on the sputum, when present they are almost invariably in clumps of some size. L. S. Dudgeon and C. H. Wrigley have elaborated¹ a staining technique for detecting neoplastic cells in sputum, which is a further development of a method for the quick diagnosis of malignant tumours published by Dudgeon and C. V. Patrick some years ago.²

Wet films from sputum are fixed in Schaudinn's fluid, prepared by adding one volume of absolute alcohol to two volumes of a saturated aqueous solution of mercuric chloride. Immediately before use glacial acetic acid is added to the strength of 3 per cent. Fixation is achieved by immersing the slide in the fluid for 20 minutes; but if a rapid diagnosis is needed an immersion of two minutes is enough. The slide is then transferred to methylated spirit to which a few drops of tincture of iodine have been added and is then washed in distilled water. Films are stained for about two minutes or less in Mayer's hemalum (hematoxylin 1 g. dissolved by heat in 1000 c.cm. distilled water; to this are added 0.2 g. sodium iodate, 50 g. ammonia alum, and finally 20 c.cm. glacial acetic acid). The slide is then transferred to tap water and counter-stained with a weak solution of eosin.

Sputum from 58 cases of suspected malignant growth of the lung or respiratory tract was examined by this method. In 26 (68 per cent.) of 38 proved cases of carcinoma of the lung or larynx it was possible to establish the diagnosis from the examination of the sputum, and in the majority of instances the histological type of growth present could be distinguished. Particles of new growth in sputum, when fixed and stained by the authors' method, presented two different types: (1) The common form associated with oat-cell carcinoma. These fragments, which stain deep blue, consist of a cluster of cells containing typical oat-shaped cells. (2) Fragments of squamous or columnar cell growth. The individual cells in this group are differentiated from those of the oat-cell variety by their greater size, larger nuclei, and a considerable amount of protoplasm which stains

pink with eosin. The fragments stand out prominently in the films and can be seen with 2/3 objective. The blood-streaked portions of the film are those in which the carcinoma fragments are most likely to be found. The authors add a short description of the various types of inflammatory cells found in sputum which may be confused with carcinoma cells.

AN EXCURSION INTO VITAL STATISTICS

IN last week's issue of the *New Statesman and Nation* attention is drawn to the fallacy of using crude death-rates as a measure of success or failure in the hygiene of a community. Since the force of mortality varies considerably with sex and enormously with age, the crude death-rate—i.e., the total death-rate at all ages—must largely depend on the age- and sex-constitution of the population under consideration, and the comparison of such rates between one area and another may be very fallacious. It is therefore idle, as the *New Statesman* points out, for people to say that there can be no serious malnutrition in the depressed areas because the crude death-rate is not appreciably higher in South Wales and Durham than in the rest of the country. This kind of argument may have been advanced by irresponsible persons; certainly no government department or private person with any knowledge of vital statistics would dream of putting it forward. For a comparison of any validity at all the first essential is a standardised death-rate, or (better still) death-rates by ages for each sex; the second essential is a yardstick against which to assess their normality or abnormality. The comparison adopted by the *New Statesman* is that between the observed deaths in the depressed areas in 1934 in each sex and in four broad age-groups, and the deaths that would have occurred in these areas if the inhabitants had suffered the same death-rates in each group as prevailed in England and Wales as a whole in 1934. By this procedure it is found that whereas the expected deaths were 105,181 the actual deaths were 126,508, an excess of 20 per cent.; "21,000 died," it is concluded, "before their time because they were poor." When attention is transferred from the total deaths to the deaths in particular age-groups and for males and females the excess is found to be greatest in childhood and greater among females than among males. From such figures two main conclusions are drawn: first, that the difference in the death-rates between the depressed areas and the rest of the country is greatest in the case of children; and secondly, that among the adult population women "are being sacrificed more generously than men." If these conclusions, derived from a few hours' simple work, are justified, they are obviously of the very highest importance and must show gross neglect of vital statistics on the part of those in authority. Our own view, however, is that the comparison which has been adopted is as misleading as the use of the crude death-rates that the *New Statesman* justly stigmatises. To reach the "expected" deaths in the depressed areas the rates of the whole country, it will be noted, are being applied to a particular section of it, a large part of which lies in the north of England. It is well known that mortality in this country increases steadily as we pass from south to north—whether the reason be malnutrition, climate and lack of sunshine in smoky areas, overcrowding, or something else. This feature has been observed year in, year out, long before the economic depression. Thus, if we apply the death-rates of the whole country to any industrial area of the northern counties, whether

depressed or flourishing, there is very little hope of its making a favourable showing under the test. Even in their heyday the county boroughs of the north would have come out unfavourably. Similarly it should be noted that the death-rates of the whole country include within them the lower rates prevalent in rural areas; the number of county boroughs in any part of the country, depressed or flourishing, that have standardised death-rates below the rate for England and Wales as a whole is relatively small. In such a comparison, therefore, we are not comparing like with like. It may be that the county boroughs as a whole have higher death-rates than the rest of England and Wales because of their poverty and all that it denotes. But this, unfortunately, is not a prerogative of the depressed areas. Before we can show mathematically that the experience of these areas has been affected, in addition, by their present economic state, as the article in the *New Statesman* suggests, we must demonstrate a rise in mortality, or a slackened rate of decline, in these particular parts which is not apparent in other areas, as far as possible similar in all other respects, but not suffering severely from the depression. To secure such a satisfactory comparison is exceedingly difficult, and the detection of cause and effect is still harder. The question of the health of the depressed areas cannot in fact be answered by superficial statistical methods.

THE ORIGIN OF THE MILK SUGAR

SOME striking observations on the production of the milk sugar, lactose, by the active mammary gland are recorded by Grant.¹ The physiological evidence which had previously accumulated, in particular that provided by Paton and Cathcart and by Nitzescu, strongly suggested that the lactating breast is capable of extracting glucose from the blood and of converting it into lactose. The new evidence comes from a study of the synthesis of lactose by active gland in vitro. Slices, 0.5 mm. thick, of the mammary glands of freely lactating guinea-pigs were kept aerated in physiological salt solutions for six hours at body temperature. It was found that when glucose was present lactose synthesis occurred, the gland tissue producing this sugar in amounts equal to 2–4 per cent. of its own weight. (Probably the actual synthesis was considerably greater than this, since in control experiments lactose was found to disappear from the gland.) Although lactose consists of glucose condensed with galactose, the addition of galactose alone to the gland tissue did not result in lactose synthesis. Hence, whilst the galactose part of the lactose can be formed from glucose, the glucose part cannot be formed from galactose. Further, it appears that galactose can be formed from glucose only when it is to become a part of the lactose molecule; "no evidence has emerged," Grant says, "of the synthesis of galactose in the free state, but only of this sugar combined through its first C atom to the fourth atom of a molecule of glucose forming lactose."

Nitzescu² found that in the fasting animal the lactose content of the milk was lowered, but the normal level was restored by the injection of glucose, galactose, fructose, and maltose. His experiments could not show whether the last three sugars were converted into lactose directly, or only after preliminary transformation into glucose. In the new experiments Grant has found no definite lactose

¹ Grant, G. A.: *Biochem. Jour.*, 1935, **xxix**, 1905.

² Nitzescu, I. I.: *Compt. rend. Soc. de biol.*, 1925, **xciii**, 1319.

synthesis from galactose, fructose, and mannose, but the question is still not answered. For the mechanism by which these sugars are converted into lactose in the gland, if it exist, might be damaged under the artificial conditions *in vitro*, whilst the synthesis from glucose might rest on a more stable mechanism. Such considerations as these must always be borne in mind to avoid the dangers of attempting to apply to the living animal what is found to happen in the flask. These dangers are increasing now that many stimulating results are being obtained with the tissue-slice technique; such, for example, as those obtained by Krebs² on urea and ammonia formation. The present work, however, is at the worst an interesting *in-vitro* demonstration of a sugar inter-conversion; whilst, on the other hand, it may be of considerable physiological significance.

HEREDITARY OPTIC ATROPHY

THE clinical picture which passes under the name of hereditary optic atrophy has been well recognised since Theodor Leber's classic description appeared in 1877. It cannot however be said even now that the mode of inheritance is clearly established; so much so is this the case that some authorities speak of "modes" of inheritance rather than "mode." How serious are the gaps in our knowledge has been shown by the critical surveys beginning with that of Nettleship in 1909 and continued by numerous authors. To reduce the mass of pedigrees that have been published into some sort of system, different writers have found themselves compelled either to assume varying modes of inheritance—even to the extent of a change in the mode within the same family—or to assume that in addition to typical Leber's disease there are a number of conditions which simulate it. The last explanation has been made plausible by the work of Behr, Drexel, and others. Drexel has shown that central nervous system lesions are present in some of the families described as suffering from Leber's atrophy, whilst Behr has drawn attention to what he calls "complicated" hereditary optic atrophy of childhood, a condition in which the complications are by no means clear-cut and may have been due to cranial deformities in the particular family reported. It is of course possible that cases of Leber's disease, attracting as they do the attention of ophthalmologists rather than of neurologists, may not have been as fully investigated as might be desired, but the fact remains that carefully collected pedigrees do not always conform to the requirements of a sex-linked recessive character. Fleischer and Josenhans have escaped this dilemma by attempting to exclude from the picture of Leber's atrophy cases which run an atypical course, such as those ending in either complete blindness or considerable recovery. But even such an arbitrary procedure does not clear up all the difficulties, for the sex distribution though satisfying theoretical requirements in broad outline shows difficulties in the numerical incidence. Thus it is difficult to explain both the high incidence of affected sons and the high incidence of carriers amongst unaffected daughters. An escape into the explanation of "irregular dominance" is not warranted. It is of course not necessary to assume that Leber's atrophy is not a sex-linked recessive when it appears in women, for such women may be homozygous. None the less there is evidence from the work of Japanese observers that the condition or

one simulating it may be dominant, being transmitted directly from generation to generation. Recently Dr. A. H. Thompson and Mr. G. T. W. Cashell¹ have examined a family with hereditary optic atrophy showing a number of divergences from typical Leber's disease. The atrophy appears to have been present at birth; the sex-incidence was equal, if not actually excessive, for females; inheritance was dominant through affected mothers; and instead of central scotoma there was shrinking of the peripheral field, with progressive diminution of vision and ultimate complete atrophy of the disc. The great interest of this family lies in the transmission through an affected female to the exclusion of transmission through males. Such sex-linkage raises important theoretical points.

THE INVESTIGATION OF CANCER

THE £32,000 which the British Empire Cancer Campaign has been able to distribute during the past year has been spent in two ways: first on purely experimental investigation of the causes of cancer, and secondly in attempts to improve known methods of treating it. The campaign does other important work in disseminating information, linking separate centres, and educating the public; but its twelfth annual report, presented this week, is naturally devoted mostly to the results of research.

The experimental study of cancer tends to concentrate at present on two main problems: the changes in the cell that lead to neoplasms, and the factors that bring about these changes. The work of Prof. E. L. Kennaway and Prof. J. W. Cook at the Cancer Hospital has shown that it is possible to produce cancer by the repeated application of pure chemical substances, closely related chemically to the sterols; so that we are on the track of changes by which substances always present in the body can be rendered carcinogenic. An investigation is being undertaken, for example, at the Cancer Hospital on the way in which excessive sunlight will cause epithelioma of the skin—an investigation which raises the question whether ergosterol (the source of vitamin D) may not be converted by light into a slightly different chemical compound which induces malignant change. In Manchester Dr. C. C. Twort and his colleagues (whose latest work is reported on p. 1226 of our present issue) find difficulty in distinguishing the mechanisms that lead to dermatitis from those that lead to cancer; in their view cancer "is a defensive process, and not a purposeless, useless process as defined by early pathologists." Suggestive evidence is brought forward, moreover, from the Mount Vernon Hospital that "the growth rate of the tumour cells may alone determine innocence or malignancy." At Leeds the possibilities of inhibiting the neoplastic process are being further explored, and Dr. I. Berenblum reports that cantharidin as well as mustard gas will interfere with the carcinogenic action of tar. These two substances have totally different chemical constitutions, and it looks as though the inhibition was associated with a special type of cell change rather than with chemical structure of the inhibitor.

One of the noteworthy advances of recent years has been Prof. McIntosh's demonstration at the Middlesex Hospital that in fowls tar-induced tumours can be propagated through filtered extracts. This brings carcinogenesis in mammals into some sort of relation with the filtrable malignant tumours of

² Krebs, H. A., and Henseleit, K.: *Zeits. f. physiol. Chem.*, 1932, ccc., 33; Krebs: *Ibid.*, 1933, ccvii., 191.

¹ *Proc. Roy. Soc. Med.*, 1934-35, xxviii., 1415.

birds, which behave as though produced by a virus. Some of Prof. McIntosh's tumours have now passed through 30 passages and they are held to show the characteristic metabolism of true malignant growths: "in the case of the fowl it appears, therefore, that carcinogenic agents act only as stimulants of proliferation (hyperplasia) and that their action is ancillary to malignancy and not the cause." Prof. E. Mellanby brings forward experiments showing that the filtrable agent of a Rous sarcoma attaches itself readily to the normal cells of the body. Meanwhile information about the nature of these filtrable agents is being derived from another source. The method of high-speed centrifugation which has lately led to striking advances in our knowledge of the viruses of infectious diseases has been applied by Prof. McIntosh to filtrates from sarcomas, and by spinning these at a rate of 40-60 thousand revolutions a minute a concentrated residue has been obtained, showing that the infective agent is particulate and therefore probably a virus.

On the clinical side of pathology it is interesting to find a not unfavourable report from Birmingham on the vanadic acid reaction introduced by Bendien. The investigators believe that "although the reaction is not absolutely specific for carcinoma, it affords a very helpful means of estimating the patients' response to therapeutic measure, and is of definite prognostic value." The report also contains an account of important work on the spread of malignant tumours of the bowel, which is being done at St. Mark's Hospital. Dr. Thomas Lumsden at the London Hospital continues his endeavour to prepare effective anti-cancer sera and similar attempts are being made at the Middlesex. At Sheffield Prof. Mellanby holds out hope of its being possible to make use of the toxic action of cobra venom on cancerous tissue and simultaneously antagonise its harmful effects on tissues by means of anti-venom serum. Renewed efforts to increase the influence of X rays by injecting substances which will make a tumour more sensitive to them are being made at the Middlesex Hospital, with promising results, and in many parts of the radiological front there are other small advances to report. At St. Bartholomew's Hospital it is proposed to install an X ray apparatus with a voltage of a million; "the amount of radiant energy produced by such a machine will exceed," it is said, "that of any form of radium 'bomb' at present in use or designed." Also from St. Bartholomew's Dr. W. M. Levitt presents striking results in the treatment of carcinoma of the œsophagus with large doses of X rays—a method whose usefulness is unfortunately limited by the danger of damage to lungs. At Newcastle and elsewhere preliminary work is being done on the action of short wireless waves on the living cell. These are only a few of the directions in which inquiries are being pursued, and no one can read the report without astonishment at the diversity of knowledge—much of it from unexpected sources—that is now being applied to research on malignant disease.

BACTERIAL ALLERGY

CLINICIANS and pathologists have for some time wanted an answer to the question whether a skin response to the intracutaneous injection of a bacterial vaccine indicates an allergic state induced in the patient by similar bacterial antigens. It is obviously unsatisfactory to label an organism isolated from the sputum of an asthmatic patient as the cause of the allergic state solely on the grounds that it gives,

when injected as a vaccine into the patient's skin, a larger reaction than any of the other organisms obtained from the same sputum. Much work is necessary to determine, first, to what extent positive reactions to bacterial vaccines occur in persons displaying no allergic phenomena, and, secondly, if such reactions are found to be positively correlated with allergic phenomena, to discover what part of the complex mixture of antigens in the bacterium is responsible for the reaction. The specific substances, mostly polysaccharide in nature, of many bacteria are known to produce anaphylactic shock in specifically sensitised experimental animals. The work of Tillett and Francis¹ and of Finland and Sutliff² has shown that an immune response to the pneumococcus in the course of acute lobar pneumonia results in the sensitisation of the skin to the injection of the specific polysaccharide of the infecting organism. Dr. Harley³ now brings forward further evidence on this subject and describes a small series of experiments indicating that the allergic response to injection of pneumococcal vaccines is twofold. The first part of the response is specific and related to the high virulence of the pneumococci used to make the vaccine and to the type-specific immunity and anaphylactic sensitisation to specific polysaccharide; the second is produced by the injection of vaccines from both virulent and avirulent pneumococci, and is not type-specific, since skin reactions can be obtained in animals so immunised by injection of any type of pneumococcus or of the *Streptococcus viridans*. The work is welcome as an indication that bacterial allergy is being examined in the light of the very extensive work on the antigenic analysis of bacteria that has been taking place during the last fifteen years.

QUADRUPLETS IN HOLLAND

A CASE of quadruplet pregnancy is reported by L. J. Frijda (Nederl. tijdschr. v. geneesk., 1935, lxxix., 4890).

The mother, aged 31, had already had three children, the youngest in September, 1934. One menstrual period followed the birth of this child, in October, 1934, after which there had been amenorrhœa. In January, 1935, she noticed swelling of the legs, and in February began to suffer from vomiting, headache, and backache, for which she consulted Dr. Frijda. She had at that time a blood pressure of 155/85, œdema of the legs, and slight albuminuria. The uterus was not unduly large. On a salt-free diet the œdema and albuminuria disappeared, and the pregnancy was therefore allowed to go on. Until labour set in, multiple pregnancy had not been suspected. Pains began on July 9th, 1935, at 6.30 A.M. The first child was born alive at 10.15 A.M. but the uterus did not become appreciably smaller, and it was realised that the case was one of multiple pregnancy. Five minutes later a dead and macerated fœtus was born, followed in another five minutes by a living child. Fœtal parts could still be felt, and internal examination revealed an unruptured amniotic sac containing the fourth fœtus lying transversely. The membranes were ruptured and the child manually delivered; it was macerated. The placenta, expelled spontaneously 15 minutes later, was single, with the four umbilical cords inserted symmetrically near its edge. It weighed 2 lb. 9 oz. and measured 27 in. across. The chorion was single. The amnion was double, one of the sacs having enclosed three of the children. The children were females. The first living child weighed 3 lb. 8 oz., the second 3 lb. 13 oz. Both did well, and the puerperium was uneventful.

Frijda points out that uniovular quadruplet pregnancy is extremely rare. He can find records of only two cases.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXIX.—PROGNOSIS IN INTERNAL DERANGEMENT OF THE KNEE-JOINT

THE term internal derangement of the knee-joint is often used as if it was synonymous with injury of the semilunar cartilage. It actually, however, includes a much wider group of cases, and it is because it is used with this general significance that there is considerable misconception of the prognosis in straightforward cases of injury of the semilunar cartilages. It is convenient to keep together a group of cases in which there is a derangement of normal functions of the knee-joint either (1) as a single isolated incident, or (2) as an incident which recurs at more or less frequent intervals. The defect may be: (1) interference with full normal mobility, shortly described as locking; (2) loss of stability from muscular insufficiency; (3) loss of stability from hypermobility.

In (1) the defect may be temporary, terminating as soon as the mechanical obstruction is removed. In the case of locking by a displaced cartilage or loose body, the obstruction may disappear by a natural movement or as the result of manipulation. In (2) muscular insufficiency may be expected to correct itself or can be overcome by appropriate treatment as soon as its cause has been removed. In (3) hypermobility is due to rupture or laxity of the crucial or other ligaments. It will continue to disable the joint unless it can be overcome by mechanical or surgical means.

RECURRENT DERANGEMENT

It must be recognised that recurrent symptoms may be due to any of the three causes already mentioned: recurrent locking may result from the presence of a torn or hypermobile cartilage or of a loose body; recurrent collapse of the knee may occur because of weakness of the quadriceps muscle; and recurrent subluxation takes place when the crucial ligaments are lax. But recurrent derangement of the knee may also result from other conditions such as lateral subluxation of the patella and effusion in cases of osteochondritis dissecans or of synovial cysts. And it must also be remembered that a mild inflammatory lesion of the knee may be lit up by slight trauma, which produces effusion, pain and loss of movement, and may perhaps lead to the diagnosis of internal derangement.

The difficulty of definition and sometimes of accurate diagnosis renders it necessary, when considering prognosis, to confine the discussion as far as possible to definite pathological lesions. It would be impossible in a short space to deal adequately with all the conditions which might be included under internal derangement of the knee-joint. Further consideration here will therefore be confined to (1) injuries definitely diagnosed as due to damage of the internal and external semilunar cartilages, with displacement at the first accident, and (2) recurrent derangement (collapse, locking, or effusion) due to injury of a semilunar cartilage, the presence of a loose body, or displacement of an uninjured external semilunar cartilage (snapping knee in its major and minor varieties).

LOCKING OF THE KNEE AT THE INITIAL INJURY

When a knee becomes locked as the result of a twisting strain, it is the custom with most surgeons

at the present day to treat the condition by manipulation and to refrain from operation unless manipulation fails or unless there is later a recurrence of symptoms. But before manipulation is carried out it must be presumed that every care has been taken to exclude conditions other than an injury of the semilunar cartilages. An X ray excludes fracture of the tibial spine, bony loose body, and fissured fracture of the patella. Lateral dislocation of the patella and injury of the internal lateral ligament must also be remembered. In the last named (a common accident), manipulation is positively harmful and delays recovery.

Presuming that the diagnosis of injury and displacement of one of the cartilages has been confirmed, manipulation under an anæsthetic may have one of the following results:—

(a) The joint may be immediately and completely comfortable, movement is full, and although there is probably some effusion, this disappears rapidly, and the muscular power returns quickly with use. This result indicates that the torn cartilage has either returned into its normal position or at least that it has passed into a position in which it is no longer obstructing movement.

(b) There may be considerable improvement but extension of the knee may still not be quite complete. With subsequent treatment by massage, faradic stimulation of the quadriceps and exercises, the improvement continues until at the end of two or three weeks the function is nearly normal. This probably indicates that the cartilage is split round the margin (bucket handle split); it has not returned to its normal position but is displaced centrally into the intercondylar notch. This occurs frequently in the case of the internal cartilage. It may occur, but not commonly, in the external.

(c) There may be little or no improvement as the result of the manipulation, and only very slow improvement as the result of after-treatment. This probably indicates that the position of the cartilage has not been affected by the manipulation, and that it is blocking the movement as badly as ever. It indicates the advisability of operative interference provided that there is a reasonable certainty that the diagnosis is correct. The possibility that the case is one of injury of the internal lateral ligament should always be reconsidered. In such a case the knee may be expected to extend easily and without force whilst the patient is under the anæsthetic, flexion recurring however immediately afterwards.

In a considerable proportion of cases the manipulation may be expected to restore the function of the knee at least for the time being. The prognosis as to the future in such cases is important but difficult. Some surgeons advise a considerable period of rest or even of immobilisation after the initial injury. They apparently hope that the torn cartilage will heal or that possibly the torn portion will become adherent in a place in which it is doing no harm. Experimental and operative experience is all against this treatment. It would seem that repair does not occur in the semilunar cartilages themselves, and at operation a torn portion of cartilage is never found to be adherent in its displaced position. Clinical evidence is also against prolonged rest and immobilisation. Recurrence of symptoms at a later date is just as likely to occur after such

treatment as after early use. Moreover, all are agreed that restoration of muscular power is important, and this can only be attained by use.

When a knee has recovered, either naturally or as the result of manipulation, from the first injury, it is quite impossible to predict its future behaviour. In some cases no recurrence occurs even when fairly strenuous exercise (golf, tennis, rackets, swimming) is taken. In some cases recurrence of locking or of other symptoms results from quite simple movements. There appears to be no way of forecasting the future. A very guarded prognosis should therefore be given and the patient should be warned that the knee may give way with or without locking, or may swell as the result either of a twisting strain or simply as the result of increased exercise. It may be said, however, that after a definite cartilage injury the knee cannot be expected to stand up to forms of exercise which involve a considerable risk—e.g., football, hockey, ski-ing. Those who wish to continue these pursuits should always be advised to submit to operation when there has been a definite cartilage injury. The same applies to cases in which an unstable knee involves a special risk—e.g., mountaineers. It is doubtful whether after injury of the external cartilage recovery with a reliable knee ever takes place without operation. As a rule when this cartilage has been injured any strenuous exercise produces pain and swelling even if recurrent locking does not occur. This is explained by the lesions that are usually found at operation upon this cartilage. When the external semilunar cartilage is found to be injured there is usually either a bucket handle tear around the margin, the greater part of the cartilage being separated, turned over and displaced to the inner side of the external condyle, or else there is a crush or tear of the cartilage opposite the external lateral ligament, a considerable part of the cartilage being crushed between the condyle and the head of the tibia and its substance frayed out.

PROGNOSIS AFTER OPERATION

In the average case in which the diagnosis of a torn semilunar cartilage, or a loose body or of a hypermobile external cartilage, has been proved correct at operation and the cartilage or loose body has been removed, the prognosis is excellent. A very large proportion of patients have a knee which is not only normal for all ordinary purposes but which is strong enough to permit them to indulge in the most active forms of sport with safety. They are able to play football (both games), hockey, and tennis, and to ski and swim.

FAILURES

That there are failures to secure a really satisfactory result must be acknowledged, as in the case of every other operation. But these are not numerous, and they diminish in number as surgeons become more skilful in diagnosis and treatment.

Infection of the joint is the one cause of real catastrophe. At the present day it is so rare that it need hardly be considered. It should however be borne in mind that if a septic focus exists in the body a blood-borne infection may extend to the knee as to any traumatised area. Patients sometimes desire to have minor operations, such as the extraction of a tooth and removal of tonsils, carried out at the same time as an operation upon the knee. Such procedures, involving risk of infection, should be absolutely prohibited. They have been the cause of some of the catastrophes.

Injuries of the ligaments at the time of operation may leave hypermobility afterwards. Needless to say, incisions must be planned in such a way as to damage the knee as little as possible. The internal and external lateral ligaments, crucial ligaments, and attachment of all parts of the quadriceps muscle must be respected.

Imperfect after-treatment may have failed to restore complete movement and strength. The test should be that the patient is able to do a tip-toe, knee-bend exercise right down on to the heels and up again with equal weight on both feet, and also to kneel and sit right back on his heels. Such a result is attained in the average case in six to eight weeks. Post-operative hæmorrhosis occurs occasionally in the practice of practically all surgeons. It is a troublesome and painful complication which does not affect the ultimate prognosis, although it considerably delays recovery of normal function.

Failure at operation to find sufficient damage to account for the symptoms or failure to find and remove the whole of the trouble has in the past been a frequent cause of unsatisfactory results. Naturally if the injury has not been found and removed, recurrence of symptoms is probable; the more definite the injury discovered the better the prognosis.

The presence of an *additional factor*—e.g., laxity of the crucial ligaments—sometimes occurs in conjunction with an injury of a semilunar cartilage. The patient remains liable to the symptoms due to the additional factor, such as weakness and the liability of the knee to subluxate.

Wrong diagnosis.—Perhaps the most frequent mistake is the failure to diagnose recurrent subluxation of the patella, and early arthritis.

Late recurrence of symptoms of locking due either to injury of the other cartilage which has been left behind or to the formation of a loose body. There appears to be a definite, although slight liability to the formation of loose bodies after cartilage injuries, probably from fragments of cartilage lying loose in the articular cavity.

Age.—Although naturally young patients make the most rapid recovery after operation, age is not necessarily a contra-indication of operation for internal derangement of the knee-joint. This injury occurs sometimes in patients over 60 years of age, and loose bodies are not uncommon in people of this age. Operation may be undertaken with safety and perfect results obtained. The removal of both internal and external cartilages from the same knee is sometimes necessary. After such removal the knee functions in a perfectly satisfactory manner.

Arthritis.—There is naturally some fear lest removal of a semilunar cartilage may cause later on an arthritis of the knee. Certainly a knee-joint in which there has been an internal derangement is rather more likely to be the seat of subsequent arthritis than a normal knee. But it is very doubtful whether the operation is in any sense the cause of the arthritis. In fact it would seem that arthritis occurs much more frequently in cases in which an injured cartilage or loose body has been allowed to remain in situ for several years and to cause persistent symptoms. A very large proportion of cases remain free from arthritic changes after operation, and the removal of an irritating foreign body would appear to be a preventive rather than a cause of arthritic changes.

GAS-AND-AIR APPARATUS FOR MIDWIVES

BY JOHN ELAM, B.A. Camb., M.R.C.S. Eng.

VISITING ANÆSTHETIST TO THE WELLHOUSE HOSPITAL, BARNET

Two years ago Dr. R. J. Minnitt, of Liverpool showed¹ how, by the use of an automatic apparatus which delivered to the patient a mixture of nitrous oxide and air, the pains of labour could be satisfactorily relieved without danger to mother or child and without hindrance to the work of the accoucheur. Since its introduction, Dr. Minnitt's method has been thoroughly tested, and there appears to be only one obstacle in the way of all parturient women enjoying the relief which gas-and-air analgesia can give—namely, the fact that a large proportion of confinements are attended by midwives without the presence of a doctor. Midwives are not at present allowed to administer analgesia to their own patients, and before this ban is lifted the gas-and-air apparatus must be made available for the midwife and reasonably easy for her to carry about.

The gas-and-air machine devised by Dr. Minnitt is suitable for use in hospital, but even the so-called portable model with its two heavy gas cylinders would be a formidable burden for district midwives, who are not equipped with motor-cars. If gas-and-air is to come into general use, some way must be found of separating the mechanical part of the apparatus from the cylinders. At the Wellhouse

Hospital, Barnet, we have had made for us a cheap metal stand holding two gas cylinders joined by a coupling to which the mechanical part of Dr. Minnitt's apparatus can be screwed when desired. This device solves the problem of portability, the stand and cylinders being sent to the patient's house when the confinement is due, the midwife bringing with her only the actual machine, which only weighs 5-6 lb., to be attached to the

FIG. 1.—Sketch of the portable Siebe Gorman gas-and-air apparatus ("Nitrox") in its case, with two 100-gallon gas cylinders. The whole weighs about 30 lb.

stand when she is ready to administer the gas-and-air. Two new gas-and-air machines have recently been tested at the Wellhouse Hospital.

I

First there is Messrs. Siebe Gorman's apparatus of which there are two models, one with a fixed gas percentage, the other with a variable one. In this apparatus (Figs. 1 and 2) the gas flows through a pressure-reducing valve R and thence into a chamber A closed by a rubber diaphragm and valve. From this chamber gas is led to the patient by means of tubing and face-piece. A pressure gauge G shows at what pressure the gas is flowing.

When the patient inhales the valve is lifted, pressure is reduced in A, and the rubber diaphragm is drawn forward

pressing on a lever which allows gas to flow. As the gas flows, air is drawn in and the patient receives a constant percentage of gas-and-air (60 per cent. gas). When the patient ceases to inhale, the diaphragm in A expands and allows the lever to shut off the flow of gas.

In the variable percentage model there is a dial D behind the pressure gauge on which are numbers representing the percentage of gas in air. By turning the dial one of these numbers comes opposite an indicator and this number gives accurately the percentage of gas in air which the patient is receiving.

The machine is attached to a large wheeled stand holding 2 by 200 gallon gas cylinders for hospital use, or it fits into a convenient case (Fig. 1) with 2 by 100 gallon cylinders, to make a portable apparatus weighing about 30 lb.

II

The second apparatus (Figs. 3 and 4), made by the Dental Manufacturing Com-

pany, is extremely simple in design. Here the machine can be separated from the stand and cylinders simply by unscrewing one nut Z on the coupling between the cylinders. The gas from the cylinders flows into a reducing chamber A, where the pressure is reduced to $\frac{1}{2}$ lb. per sq. in. by means of a rubber diaphragm controlling a needle valve. At the top of chamber A is an adjusting screw R enclosed in a screwed-on cap and the pressure in the chamber can be varied by turning the screw R. The percentage of gas in air is proportional to the gas pressure in A.

The needle of the gauge in front of the chamber A shows at what pressure the apparatus is working. The optimal pressure for the average case has been found to be $\frac{1}{2}$ lb. per sq. in. and the gauge is lettered accordingly. The gas from chamber A then passes through a carburettor E, designed specially for gas-and-air work by Mr. A. L. Bird, of Cambridge University Engineering Laboratories, and the gas flow is controlled by a float which rises sucking in a mixture of gas-and-air through appropriate inlets when the patient inspires. When the patient takes a deep breath the float rises and gas flows from chamber A into E; the pressure on the diaphragms contained in A is reduced, causing a needle valve in A to rise and allow gas to flow into A. On the patient ceasing to inspire, the whole flow of gas is cut off by the float in E falling into position, closing the gas and air ports, stopping the flow of gas by increasing the pressure of the diaphragm in A and thus closing the needle valve. On the tubing which leads to the face-piece is a safety valve which blows off at 3 lb. per sq. in. in the event of the pressure rising too high from any cause.

The machine is screwed to the stand at the joint Z, and this stand holds two 15 in. straight-valved 100 gallon

FIG. 2.—Mechanical part of the same apparatus, weighing 5-6 lb., removed from the case.

¹ THE LANCET, 1934, I., 519, 1278.

gas cylinders held in position by rings and thumb screws. These cylinders are fitted with clip-on labels "FULL" and "IN USE," to avoid confusion.

At the Wellhouse Hospital we have tested carefully all three of the machines described, and we find that each gives satisfactory results in use. The

FIG. 3.—Sketch of the Dental Manufacturing Co.'s portable gas-and-air apparatus, with two 100-gallon gas cylinders in a cheap metal stand.

individual user must decide which apparatus to choose. To produce an apparatus which will give to the patient a mixture of gas-and-air requires some little skill and ingenuity; but to give to the world a solution of a problem which has baffled mankind since the beginning of time is something of which any man may well be proud. And this is Dr. Minnitt's achievement.

I cannot conclude this technical note with-

out dealing briefly with the two difficulties which have been held to lie in the way of the full development of the method—namely, the competence of the midwives to administer gas-and-air analgesia, and the cost of the gas itself. Here at the Wellhouse Hospital the midwives are in fact administering the analgesia,

FIG. 4.—Mechanical part of the same apparatus, unscrewed from the rest, and viewed from behind.

long the natural course of labour, but in our work here we have seen no evidence of such prolongation by gas-and-air analgesia. The cost of the gas is another consideration. Widely variant estimates have been given, but here the cost is working out at about 2s. per case, possibly a little less, and there are, I think, few women who will not be glad to pay (say) 2s. 6d. for the relief they obtain.

The lettered diagrams have been kindly prepared for me by Mr. H. G. Warren.

MATERNAL MORTALITY

A DISCUSSION BY THE FELLOWSHIP OF MEDICINE

On Nov. 13th the Fellowship of Medicine promoted a debate on the motion

That the Present Rate of Maternal Mortality is a Discredit to Modern Obstetrics

The debate was held in the Barnes Hall of the Royal Society of Medicine and the chair was occupied by Dr. T. WATTS EDEN.

AFFIRMATIVE

Dame JANET CAMPBELL (late Ministry of Health), opening in the affirmative, explained that she was speaking as a public health officer rather than as an obstetrician, which latter she did not claim to be. The association between the public health service and obstetrics was a comparatively recent one, and was the result of an attempt to solve the question of infant mortality. This had led the health service and the Ministry into clinical country, and the concern of both now was to improve the midwifery service generally. Dame Janet complained that the public health service had not received from the obstetric speciality the support it had the right to expect; the initiative ought to have come from the latter, as the reduction of maternal mortality was primarily a clinical problem. Childbirth was physiological, it only occasionally became pathological; if

obstetricians had been less fully occupied with the abnormal, more attention would have been devoted to the great bulk of midwifery work—namely, the normal. The importance would then have been realised of securing skilled treatment whenever needed. Obstetricians acquiesced far too long in their speciality being regarded as a cinderella subject, an attitude which must have had its effect on the outlook of students and practitioners. If senior members of the profession did not take much interest in it, if extern midwifery was done in a haphazard way, and if little attention was paid to prenatal and postnatal work, one could scarcely expect that childbirth would be given the high place it deserved. Unfortunate too was the tardy recognition of the value of the competent midwife; only now was it realised how much better it would be to give her a share in the responsibility for her cases. The present position of postnatal care left much room for criticism. In the matter of analgesia during delivery, the speciality had been slow to move, and only under the pressure of lay opinion. There should be relief of pain for the poor as well as for the well-to-do woman. Lastly, the profession should have directed attention to the wide prevalence of puerperal sepsis; doctors should regard such cases more seriously than they now did.

Prof. MUNRO KERR (Glasgow), though supporting the opener, was not able to subscribe to the term "discredit"; he submitted that even before public health took obstetrics under its care, those responsible

for this work already did a great deal of teaching. He claimed that deaths during pregnancy and childbirth were mainly due to faults in antenatal and intranatal care; the women themselves were often to blame. Specialists, he thought, were doing too many Cæsarean sections and inductions of labour; some, on finding some slight abnormality, carried out one of those measures. He agreed with Dame Janet that if the profession had taken up midwives earlier, this country would now have been producing returns equal to those of Holland. The toll of childbearing women in this country was about 1 in every 200, but it varied a good deal with the district. It was a platitude that childbirth was a physiological process; he preferred to regard every pregnant woman as suspect, as she always held pathological possibilities. In a general way it could be said that these deaths occurred largely because of neglect to take the adequate measures available to prevent them. The problem in densely populated urban areas was very different from that in rural districts, and it was a great satisfaction to him to see Mr. Baldwin's announcement that a midwives' service was to be provided. Routine work should, he thought, be carried on by midwives, and local authorities should enrol a sufficient number of midwives as an integral part of their service, as was being done at Bradford. In densely peopled areas the family practitioner should, he thought, give up maternity work to the municipal midwives service, especially as practitioners now had a sufficiency ensured to them through a national insurance scheme.

NEGATIVE

Prof. GILBERT STRACHAN (Cardiff) remarked it was a wonder the word "disgrace" was not used in the motion; he thought Dame Janet had confused obstetricians with general practitioners. The obstetricians of the country were a mute army who were doing their particular work in every home in the land, and he objected to the idea that education in these matters had only followed pressure brought to bear from health authorities. Only one country in respect of which statistics were available had a lower maternal mortality than Britain—namely, Holland; yet the British figure was made a subject for condemnation. In the final report of the Departmental Committee it was pointed out that 50 per cent. of the deaths in childbirth were preventable, and that statement was re-echoed, generally with scare headlines, in most of the lay journals of the country. In New York the figure was 60 per cent. But such figures were liable to be misunderstood by the public and to be quoted in wholesale condemnation of medical practice. Meddlesome midwifery was the most important single cause of puerperal sepsis. Sixty per cent. or more of the midwifery of the country was done by midwives; when delay occurred the doctor was called in and on all hands he was conjured to "do something." Under a national maternity service abnormalities would be discovered and treated as early as possible. But maternity mortality was very complex, and what might be regarded as a certain remedy might fail in practice. Antenatal supervision had failed to reduce the mortality from puerperal sepsis. The whole question had been riddled with politics and every time blood-curdling statements were made about maternal mortality there was an increase of women who were in fear about themselves and came for reassurance.

Prof. DANIEL DOUGAL (Manchester) contended that the wording of the motion implied that modern

obstetrics had been responsible for so many deaths that it deserved to forfeit the confidence of the public; to approve of it would mean a vote of no confidence in those who were daily practising this arduous branch of medicine. Why should special attention be paid to mortality arising in obstetrics, when nothing of the kind was done in medicine and surgery? There were two reasons: (1) childbirth was a physiological process, and only incidentally did it become pathological; (2) the compulsory notification of births made it possible to calculate maternal mortality-rates more readily than those in general medicine and surgery. But the figure was misleading, because abortion and ectopic pregnancy were not included, though these accounted for 17 per cent. of the total. Avoidable deaths occurred in every branch of medicine, and official statistics were notoriously misleading. If the maternity mortality-rate was increasing, it must be due either to stricter notification or to some factors not recognised in past years. It was true that the Dutch figures were better than the British, but the inhabitants of Holland were agricultural and of good physique, as well as of placid temperament. The mortality in Britain could be reduced if all the causal factors were co-ordinated, but it was useless to talk of a first-class maternity service unless there was a readiness to pay for it. With regard to the place of obstetrics in the medical curriculum, obstetricians were apt to be out-voted in the faculty meetings. He submitted that the solution of this problem did not lie within the power of modern obstetrics alone; all the individuals and the authorities must play their part, and share in responsibility for failure.

DISCUSSION

The CHAIRMAN pointed out that the term "modern obstetrics" must be held to include all who were engaged in that service, and if anybody was to be blamed it must be all who were so engaged.

Dr. BETHEL SOLOMONS (Dublin) declared himself on the affirmative side. The medical student's present education did not fit him to practise when he was qualified; the regulations allowed him to do a certain number of confinements; they did not say he had to learn what normal labour was, and if he did not know that he could not be expected to be a judge as to an abnormal one. The student should be required to show that he had attended cases throughout, not merely towards the end. The best thing which had been done to reduce maternal mortality was to establish the College of Obstetricians. Membership of this body might well be made a criterion for appointments. Obstetrics, he was satisfied, was a beautiful science and art.

Mr. JAMES COOK (Glasgow) ranged himself against the resolution because it placed the profession in the dock. All that had been urged in support of that was the existence of a gulf between promise and performance. There were many other subjects which continued to baffle the profession. Many mothers would not take steps to ensure their safety. Among the causes of the present mortality-rate he enumerated the unborn child, the mother, the midwife, the general practitioner, institutions, the Ministry of Health, and the General Medical Council. He commended to the disputants a study of the Epistle of Paul to Philemon.

Dr. HAROLD E. WATKIN, speaking as a Lancashire practitioner, said he had brought into the world more than 3000 children, and had lost only three mothers. Disobedience was the cause of one of the

deaths, and interference from outside killed the other two. He sketched the kind of conditions in which his practice was carried on in the early days. He claimed that nowadays the younger 'practitioners' were in too great a hurry to get women delivered; they had not the necessary patience. In all his cases he insisted that no alcohol should be consumed, that there should be a daily evacuation of the bowels, and only a very small quantity of butcher's meat should be allowed.

Mr. J. T. HEWETSON (Birmingham) considered that the opener had begged the question; she did not so much make a definite charge as say if such and such things had been done the condition of affairs might have been better. Like Prof. Strachan, he deplored the fact that this had been made a political issue.

Dr. MARY KIDD (St. Leonards-on-Sea), who spoke for the motion, praised the work done by the Ministry of Health in the last 17 years. She would like to see anaesthetics much more largely used in obstetric practice; the Departmental Committee found that an appreciable cause of death in childbirth was obstetric shock; many medical men and women would agree that shock was largely due to the withholding of anaesthetics.

Sir HENRY BRACKENBURY (London) said that every one of the thirteen items of the opener's indictment had been true at some time; he believed that nearly all of them were true when he was a student, but few of them were true now. He did not agree with Dame Janet that the problem under discussion was primarily clinical; it was primarily a sociological one. Many had been pointing out for a long time that the maternal mortality was a matter of widespread national importance, but only comparatively recently had the Ministry of Health taken notice of it. The reason for the high national mortality in certain regions of the country was probably to be found in the habits and circumstances of the people.

Dr. COLIN CAMERON spoke as a country practitioner whose nearest hospital was 19 miles distant, and who often had to conduct a case by the light of a candle. Midwifery was not all it might be; one cause of risk was that too many cooks were stirring the broth. The country nurse might stop on her way to a midwifery case to attend a septic one. He spoke with gratitude of the readiness of specialists to make long journeys to help in case of difficulty.

Dr. J. R. BIBBY (Gloucester) disagreed with the motion. In Gloucester the maternal mortality was remarkably low; in ten years there were 5410 deliveries with only 2 deaths. The women attending the cases were all trained and had become midwives afterwards. Doctors had been called in 1500 times. The most important part of the service to tackle was the mother herself; many of them did not take their confinement with enough seriousness.

REPLIES

Prof. STRACHAN wished to remove any impression that Prof. Dougal and he were complacent about the present rate of mortality; but that was a different matter from being content with the criticisms levelled at their work. He had been surprised to hear Dr. Solomons say the student was not taught to understand normal labour; the student could not be taught more than fundamentals. Dr. Kidd was, he thought, misinformed about shock.

Dame JANET repeated her contention that the problem was mainly clinical, not sociological; the educational drive which had given such brilliant results at Rochdale has raised the standard all round.

The CHAIRMAN recalled the statement made in debate that one main cause of the high maternity mortality-rate was unnecessary interference. Was that, he asked, a creditable state of affairs to modern obstetrics? There was no reason to be enthusiastic about the present state of things, but he deprecated any tendency to blame one or other member of what was really a team.

On the motion being put there were:—

BRITISH ORTHOPÆDIC ASSOCIATION

THIS association held its annual meeting in Manchester on Oct. 25th and 26th under the presidency of Mr. HARRY PLATT. The opening morning was devoted to a discussion on

Fractures of the Os Calcis

The subject was considered from three aspects:—

1. *Economic results*, presented by Mr. BRYAN MCFARLAND and Mr. W. J. EASTWOOD of Liverpool, followed by Mr. J. P. HOSFORD, Mr. R. J. FURLONG, and Mr. T. T. STAMM of London. All the speakers agreed that the final result depended on whether the subastragaloid joint was disorganised or not. If it was not involved the functional result was usually excellent. Where the joint surfaces were disturbed permanent disability was likely for two reasons: (a) the development of a painful arthritis, and (b) the weakness of the calf muscles consequent on upward displacement of the posterior fragment of the os calcis. In the experience of the openers the type of treatment employed did not seem to have much influence on the ultimate function of the foot. In the few cases in which the powerful skeletal traction method advocated by Böhler of Vienna had been used to restore as far as possible the normal anatomy of the os calcis, it had not restored the patient to heavy labour any more successfully than simple manual moulding and fixation in plaster-of-Paris for several months. Nor had it shortened the time in which the patient could return to lighter occupations. The importance of factors other than methods of treatment was emphasised. These included the mental and physical condition of the injured person, his occupation, and the disturbing influence of the problems of compensation on his outlook.

2. *Results of Attempted Reduction in a Series of Recent Fractures*.—By invitation of the association, Dr. E. E. MYERS (Boston, U.S.A.) reviewed a consecutive series of 33 fractures involving the subastragaloid joint treated in the fracture services of the Ancoats Hospital and the Manchester Royal Infirmary. These were divided into two groups. (1) Eighteen fractures in which an attempt had been made, with varying success, to restore the normal anatomy of the os calcis by powerful skeletal traction and compression. More than half of this group of patients were able to return to their original arduous duties without subjective symptoms and with no appreciable impairment of the function of the foot. (2) Fifteen fractures treated only by manual manipulation and fixation in plaster-of-Paris. Of this group only a third of the patients were able to return to heavy work. Dr. Myers pointed out that the results were always better in the light, wiry type of person, and that in those patients who had achieved the best results the subastragaloid joint was clinically ankylosed. He concluded that a very definite advance

in the treatment of these fractures had been made by attempts to restore the normal anatomy of the foot, and suggested that in certain cases, after a reduction, early arthrodesis of the subastragaloid joint might be useful.

3. Treatment of Old Fractures.—Mr. R. OLLERENSHAW (Manchester) said that if a two-year period was allowed to elapse before a final analysis of these fractures was made, the general results were not so disheartening. Reviewing a series of 45 patients in all of whom the fractures were more than three years old, he had found that 34 had returned to their original work. For those who continue to complain of pain, his routine was to manipulate the foot into inversion and apply a plaster-of-Paris cast for several weeks. A very small number of old fractures required a subastragaloid arthrodesis, but this procedure could not always be relied upon to produce complete relief of symptoms.

Mr. A. H. TODD (London) recommended arthrodesis of the subastragaloid joint, and the mid-tarsal joint also if this was disorganised, after ordinary palliative methods had failed.

Bone Absorption : Osteochondritis

On the second morning the *mechanism of bone absorption* was discussed from the histological aspect by Prof. S. L. BAKER (Manchester) and from the radiological aspect by Dr. E. W. TWINING (Manchester). Prof. Baker, as a representative of the Schmorl-Turnbull school of bone pathology, maintained that bone resorption was an active cellular process in which bone was removed piecemeal by osteoclasts. In rickets and osteomalacia there is no evidence of removal of calcium salts from the bones; the pathological process is essentially a failure to calcify new bone formed during the course of these diseases, in other words, a hypocalcification and not a decalcification. He criticised the "osteolysis" theory of Leriche and Policard, who regard bone absorption as a "breaking down" of the bone into connective tissue without the aid of living cells—a process which they claim is seen particularly in Paget's disease and generalised osteitis fibrosa. Leriche and Policard admit that this process is often indistinguishable from bone formation, and Prof. Baker suggested that they had mistaken areas of coarse-fibred bone formation, which are common in Paget's disease and osteitis fibrosa, for areas of bone absorption. Thus there were two processes which could lead to diminished density of bone in radiograms:—

- (a) Hypocalcification which occurs in—
 - (1) Rickets and osteomalacia group of diseases;
 - (2) Rapidly forming coarse-fibred bone (no time for calcification or calcification delayed)—e.g., fracture callus.
- (b) Osteoclastic resorption, which accounts for all other examples of diminished bone density.

Dr. Twining agreed that so far as could be told from the X ray appearances, diminished bone density was due to actual loss of bony structure rather than to a mere removal of calcium.

Dr. M. F. JOHNSTONE (Manchester) reported 30 examples of *osteochondritis* occurring after manipulative reduction of congenital dislocation of the hip-joint in 224 children. The changes affected the femoral head and the acetabulum, and were exactly similar in X ray appearances and in the final result to those seen in pseudocoxalgia. The onset of osteochondritis did not appear to be determined by difficulties encountered in reduction.

Torticollis : Epicondylar Fractures

Mr. C. H. GRAY (Manchester) presented an analysis of 100 children between the ages of 1 and 14 years

treated for congenital torticollis. Of these 100 patients there had been difficulty in delivery in slightly over half of them. A sternomastoid "tumour" was noted in 23 babies only. In 50 both heads of the sternomastoid muscle were contracted. In discussing the results of treatment, Mr. Gray emphasised the importance of ocular anomalies. He pointed out that the eye on the affected side develops a point of false correspondence. After correction of the torticollis deformity this point no longer lies on the optical axis. To overcome this visual disturbance the child voluntarily replaces his head in the position of deformity.

Mr. Gray's contribution provoked considerable discussion as to the relative merits of the open *versus* the "closed" tenotomy of the contracted sternomastoid muscle. All speakers were agreed that prolonged and careful after-treatment was necessary to ensure complete and permanent correction of the deformity.

Mr. H. OSMOND CLARKE (Manchester) reviewed a series of 26 patients suffering from fractures of the *internal epicondyle* of the humerus with inclusion of the epicondyle in the elbow-joint. He pointed out that during the reduction of a complete posterolateral dislocation of the elbow-joint, the epicondyle may occasionally slip into the elbow-joint, but that this could be avoided by reasonable manipulative skill. More commonly, the epicondyle is torn off by a forcible abduction of the forearm on the arm which tears open the joint capsule on the mesial aspect. The epicondyle immediately enters the joint and maintains a state of lateral subluxation of the joint, which, in the absence of great swelling, can be appreciated by clinical examination. Ulnar nerve involvement of varying severity was the rule in this latter type of injury. The treatment advocated was open operation, for it allowed replacement of the epicondyle and transposition of the ulnar nerve to a safe intramuscular bed in front of the epicondyle.

Mr. OLLERENSHAW discussed the use of the *standard cinema films in case-recording*. He pointed out the many advantages of such films for demonstration and teaching purposes. Using a "cassette" camera, continuous records of a patient in all stages of his treatment could be made at any appropriate time, occupying only some 50 feet of film. Three films were shown, one of them portraying in colour the operative treatment of pes cavus, and providing very convincing evidence of the potentialities of the cinema in surgery.

MEDICINE AND THE LAW

Change of Hospital's Name and Objects

The story of the "National Anti-Vivisection and Battersea General Hospital," told in the recent proceedings in the Chancery Division, shows how the court on occasion can manage to vary the most fundamental of trusts.

According to Lord Ernest Hamilton's affidavit, it was in 1896 that a Mrs. Theodore Russell Munro opened a fund for subscriptions for a hospital to be conducted on antivivisectionist principles. Presently trustees were appointed to hold the £420 which had been subscribed and all future donations. In 1899 a site at Notting Hill seemed available. A deed at this period declared certain trusts. The hospital was to be known as the Anti-Vivisection Hospital; no experiments on living animals were to be permitted;

no person who might make such experiments or in any way encourage the practice of vivisection was to be allowed to take part as governor or manager or as member of the staff; all concerned must first sign a written declaration of opposition to such experiments; no one was to be appointed to the staff without signing a pledge that he or she would never perform any experiment, inoculation, or operation on living animals known as vivisection, would never aid or abet anybody else in so doing, and would never employ any remedies which could be "obtained only as the product of experiments on living animals such as antitoxin, pasteur antirabic virus and other like products." The Notting Hill scheme fell through, but at the end of 1900 the Battersea site was acquired for £7000 and was declared to be held on the trusts already mentioned except that the words "so long as he or she is connected with the hospital" were added to the pledge required of members of the staff. A board of management was elected at a meeting of subscribers and the hospital was opened in 1902. At the end of the year the annual report stated its objects and purposes. The hospital was declared to be established as a visible protest against the demoralising practice of vivisection; it was to be a public, charitable, and benevolent institution, and its primary object was the relief of human suffering by physicians and surgeons who were opposed to vivisection and who looked upon the result of its experiments as dangerous, misleading, and opposed to all true progress; the words "No vivisection on its staff, no vivisection in its schools, no experiments on patients" were always to be printed on the reports and appeals of the hospital. In 1908 the undertaking was incorporated under the Companies Act as "The Anti-Vivisection Hospital, The Battersea General Hospital (Incorporated)"; the memorandum and the articles of association repeated the previous declarations against experiments on animals. In later years adjacent houses were acquired to form a cancer research department, an out-patients' department was organised, and the whole premises were extended.

At the end of 1934 the excess of expenditure over income amounted to over £8000. The chairman's affidavit, dated last June, spoke of an unsecured debt of nearly £24,000 to the bank. The King Edward's Hospital Fund declined help and it was clear that the Battersea Hospital must either eliminate anti-vivisection from its name and objects or else must close its doors. It had already closed three wards, containing 100 beds, on grounds of economy. According to the affidavit, neither the chairman of the board of management nor the secretary of the hospital realised at this point that the corporate body was merely trustee of a charity and that the property and endowments of the hospital were subject to a charitable trust. When counsel's opinion was taken and the full facts were examined, the hospital was advised that, even if opposition to vivisection was a fundamental object of the company, the court had jurisdiction to confirm an alteration of the objects involving the abandonment of such opposition. Counsel advised an application to the court for a scheme "*cy près*." This law-French phrase means that when, from lapse of time or change of circumstances, it is no longer possible to carry out the donors' intention in the exact mode in which they directed, the court will allow the substitution of some variant purpose near to the original intention. Well-known examples in legal text-books explain themselves. A wood was once granted for providing timber to repair certain sea-

dykes; the sea gradually receded, dykes were no longer wanted, and the wood was entirely cut down; the court allowed the diversion of the land to other charitable purposes. Or, again, a man left funds for the relief of imprisoned debtors in Calcutta; imprisonment for debt was abolished in Calcutta, and the court applied the "*cy près*" doctrine to the disposal of the funds. In the case of the Battersea Hospital it could not be said that the objects had ceased to exist; the court was satisfied, however, that they had ceased to be practicable. It was stated that no other hospital in the country was conducted on similarly restrictive lines. Mr. Justice Eve made the necessary orders altering the name of the hospital and removing the restrictions from the trusts.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AN annual meeting of fellows and members of the College was convened for Nov. 21st at 4 o'clock. As there was an attendance of only 23, excluding members of the council, there was no quorum, and an informal meeting was held with Sir Cuthbert Wallace, the president, in the chair, to discuss the matters on the agenda.

Reviewing the work of the year, the PRESIDENT spoke of Sir Holburt Waring's visit to Australia to open the Royal Australasian College of Surgeons, and of the primary fellowship examinations held there and in India. Similar examinations were to be held in Calcutta in December, and next year, he hoped, in Australia and New Zealand. The College's scholars had been working not only in London but also in the Buckston Browne Farm in Kent, which was a tremendous asset to the College. Important work had been done on shock, and the sympathetic system and intestinal obstruction were also being investigated. The prestige of the College in research was increasing.

Dr. C. L. BAYRESON had desired to move:—

"That this forty-sixth annual meeting of Fellows and Members of the Royal College of Surgeons of England again affirms that the Members, who constitute 90 per cent. of the College, should have some representation on the Council, a similar resolution having been passed 45 times and never once lost."

He was not able to do so owing to the informality of the meeting, but he set forth his reasons for placing the motion on the agenda. The fact that the proposal had been brought forward on so many occasions showed, he said, that the members felt strongly the justice of their cause. It would be an advantage to the council and to the College as a whole to have one or more members who would voice the views of their colleagues in general practice. The art of surgery was progressing: surely the constitution of the College should also progress.

Dr. RICHARD GILLBARD, in support, said that the general practitioners of the country, with all their ability, must have something of worth to contribute to the syllabus of education of the students who were destined to follow them. The council's attitude might possibly be dictated by fear lest any members elected to it would inevitably be the nominees of the British Medical Association. If the Association could obtain this representation it would be entitled to it, and in any case six members on the council could not exercise much power. He regarded the refusal of the council to give any reason or explanation of its non-

possumus attitude as discourteous and disrespectful to the members.

Dr. H. E. WATKINS said that students of the present day required more training in the schools than they received. The council must have noticed that for a considerable number of years the average mental quality of the students had been deteriorating. There were still brilliant men, but some of the younger general practitioners reached a very low standard. In his district there were half the births of 40 years ago and four times the septic cases.

Dr. HOWARD STRATFORD said that in three or four years this hoary and venerable resolution would have reached its golden jubilee and the press would take a great interest in it. The public would find with amusement and some annoyance that the farce had been proceeding for over fifty years. One day the suggestion would be adopted.

Dr. REDMOND ROCHE objected to the proposal of the council to join with other bodies in instituting a diploma in dietetics for non-medical persons. It was, he declared, against the public good that unqualified persons, under the guise, or disguise, of a diploma of the two Royal Colleges, should appear to be qualified to advise on matters of health. It was impossible for unqualified persons to decide whether an apparently healthy person was healthy or not; they could not detect early diabetes or renal disease, or recognise the idiosyncrasies of health. It was not mere fancy to suggest that these diplomates would not be content to play the rôle of skilled advisers on menus under medical direction. The new diplomates would undoubtedly intrude on the rights of the physician in dictating diets for individuals. The diploma would make another serious inroad upon strictly professional work, and it was the duty of the College to prevent, not encourage, this invasion. He suggested that the council should call a general meeting at which fellows and members could give their views.

The PRESIDENT, in reply, said that the subject had been carefully canvassed by the council and committee. The opinion of the College was rather against the Royal Colleges giving a diploma directly. It was no use however to say that they would not have dietitians; these were in existence. The University of London had started a course for the B.Sc. degree. He suggested that if dietitians must exist, it was better that they should have a nurse's training or hold the London B.Sc.

ERGOMETRINE AND ERGOTOCIN

THE QUESTION OF IDENTITY

IN March of this year we commented on the discovery by Dudley and Moir of ergometrine, a new active principle present in ergot, and referred also to ergotocin, a similar principle described by a group of workers from the University of Chicago.¹ Further observations on both these substances are now available, and the question whether they are identical or different substances deserves consideration. The late H. W. Dudley, in a paper published within a few days of his death, described very fully² the chemical characteristics of ergometrine and of several of its salts, and detailed descriptions of ergotocin have also been supplied.³ The outstanding discrepancy is in the empirical formula, for Kharasch and Legault assign a formula of $C_{21}H_{27}O_5N_3$ to ergotocin and Dudley a formula of $C_{19}H_{23}O_5N_3$ to ergometrine; in other chemical respects the substances are extremely similar and they have practically identical melting points. Dudley concludes that "ergotocin is in all probability identical with ergometrine." The pharmacological actions of ergotocin have recently been described by Davis, Adair, Chen, and Swanson⁴ and those of ergometrine by Brown and Dale.⁵ Those actions investigated by both sets of observers, with the exception of the effect on the cock's comb, are similar in every respect. Ergometrine caused cyanosis of the comb but did not lead to gangrene in a course of injections which with ergotocin produced extensive gangrene. Ergotocin, on the other hand, is said in this respect to be "more potent gram for gram than ergotocine." With this single exception, which may well be accounted for by differences in the way in which the experiments were carried out, the similarity between the two principles extends to detail; for example, both have a pressor effect when given to a spinal cat, but a depressor effect in the intact anaesthetised cat. The pressor effect of ergometrine is shown to be much less than that of the ergotocine group of alkaloids. It has only a trace of the specific paralysing action on motor effects characteristic of this group. The most important action, that on the uterus, is also the most characteristic action of ergometrine. It is the only action produced by small doses and consists in "the initiation of a long persistent rhythm of powerful contractions in a uterus normally quiescent as in the early puerperium." Brown and Dale at each stage in their investigation compare their findings on ergometrine with those of the Chicago workers on ergotocin, and the similarity in action is very obvious. They also point out the extreme difficulty of demonstrating the activity of ergometrine when present in crude extracts of ergot, except by observations on the uterus of the human patient, and this explains why ergometrine escaped recognition by the methods of experimental pharmacology for so many years.

The Chicago group of workers have just published a new study of ergotocin,⁶ in which they summarise their chemical and pharmacological results, and bring forward new clinical observations. It is unfortunate that they refer only in passing to the isolation of ergometrine, and that they do not compare their clinical findings with the original observations of Dudley and Moir.⁷ The action of ergotocin on the human puerperal uterus appears, however, to be identical with that of ergometrine as described by the British observers. The dose of ergometrine recommended by Dudley and Moir is larger than the dose of ergotocin used by the American workers who, however, state that their dose is minimal. The intravenous doses of ergotocin and ergometrine are in good agreement. Ergotocin is shown to have no detrimental effect on the blood pressure, pulse, or urinary output of patients. It has been given without ill-effect in the third stage of labour, and is stated to be more effective than any other known oxytocic drug. It is of special value in the treatment of post-partum hæmorrhage.

² Brown, G. L., and Dale, H. H.: Proc. Roy. Soc. B, October, 1935, p. 446.

³ Adair, Davis, Kharasch, and Legault: Amer. Jour. Obst. and Gyn., October, 1935, p. 466.

⁴ Dudley, H. W., and Moir, Chassar: Brit. Med. Jour., 1935, i., 1920.

⁵ THE LANCET, 1935, i., 687 and 758.

⁶ Dudley, H. W.: Proc. Roy. Soc. B, October, 1935, p. 478.

⁷ Kharasch, M. S., and Legault, R. R.: Jour. Amer. Chem. Soc., 1935, cxvii., 956 and 1140.

The place of ergometrine in clinical practice has recently been described by Moir.⁸ He concludes that ergometrine is likely to prove a valuable alternative to pituitary extract in the treatment of post-partum hæmorrhage, and he thinks it is worth trying in third-stage hæmorrhage when simple methods have failed, especially if the uterus is relaxed.

When all the evidence from chemical, pharmacological, and clinical sources is considered together, it is very difficult to believe that ergometrine and ergotocin are distinct substances. If they are indeed identical, the question arises of a single internationally recognised official name. The position is, however, complicated by the existence of two other substances each claiming to be the active principle of aqueous extract of ergot, but about which less information is available. Stoll and Burckhardt⁹ have described a substance with the same structural formula as ergometrine, extracted from ergot in a similar way and with similar chemical properties. This they have called ergobasine. Its pharmacological actions as described by Rothlin¹⁰ are essentially those of ergometrine, and it is almost certainly the same substance. It is less easy to place Thompson's^{11, 12} ergostetrine ("alkaloid X") as relatively few details of its chemical and pharmacological properties are given. It is, however, a similar principle although its toxicity in animals appears to be greater than that of ergometrine.

The isolation from ergot by Smith and Timmis¹³ of a substance isomeric with ergometrine may help to explain some of these discordant results. This substance, ergometrinine, is said to bear the same relationship to ergometrine as ergotoxine does to ergotocine. Its pharmacological properties have not yet been investigated and it probably will prove to be relatively inert, but its admixture with the pure principle may well account for minor discrepancies in the findings of different investigators.

The state of affairs with regard to these substances is very unsatisfactory, and there is a real danger that, as they become more widely used, the confusion in nomenclature may spread to the clinical field. The general position has been admirably summed up by Dale.¹⁴ It can hardly be disputed that Moir's observations published¹⁵ in 1932 afforded the original impetus to work in this field. As a direct outcome, Dudley and Moir isolated a new active principle and gave the first full and clear account of its chemical characteristics and clinical effects. Subsequent events have shown that this active principle, now well defined and fully investigated pharmacologically, is almost certainly the same as that to which other observers have given different names. Ergometrine would certainly appear, therefore, to have the strongest claims to official international recognition as the name for that active principle upon which the therapeutic action of ergot mainly depends.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

A PUBLIC MEDICAL SERVICE

As I reported at the time, the Edinburgh Public Medical Service was started in October, 1934, to meet the needs of the dependants of insured persons. The progress so far made was reviewed at a meeting last week, when Dr. John Young, who presided, said that the committee were quite satisfied with the result of the first year's working. The number of doctors in the service was 130, and during the year 3500 subscribers joined it, representing over 8000 people. The subscriptions were £3232, out of which the committee had to meet the expense of administration and the cost of prescribing. The latter proved to be heavy, amounting to 18.2 per cent. of the subscriptions received, whereas the figure under the National Health Insurance scheme was 14 per cent. The high cost was found to be due to the large number of scripts and not to expensive prescribing; 11,251 scripts were issued at a cost of £593, the average cost being about 1s. 0½d. The committee have been considering methods by which subscribers to the service may receive special treatment at reduced rates, and arrangements for special terms have been made with the radiologists in the city and with the National Ophthalmic Board.

An appeal is made to practitioners with small lists to do what they can to add suitable subscribers. The benefits which should ensue from this to the doctor are stated as follows: (1) The goodwill of his practice will become more valuable for he will have a saleable asset. (2) He is relieved of trouble and correspondence in connexion with the collection of small accounts, a proportion of which would otherwise probably be irrecoverable. (3) He can rely on receiving his payments quarterly. (4) He can pay calls on his patients when he happens to be in their district without making the patient think that he is running up an account. (5) The burden of the expense of administration will be reduced, and the doctor's remuneration thereby increased. (6) The doctors who have large lists are quite satisfied with the remuneration they had received during the first year. In a small list the law of average does not operate properly. (7) In comparing the Service with National Health Insurance practitioners should remember that they are freed from filling up various certificates and returns, and that no insurance committee or other Government department can interfere with them in the treatment of their patient.

PRISON REFORM

Improvements in the penal system were discussed by doctors and lawyers at a meeting recently arranged by the local branch of the National Council of Women and Edinburgh Women Citizens' Association, with Prof. D. K. Henderson in the chair. Dr. C. D. Bruce, medical superintendent of the Criminal Lunatic Department, Perth, who spoke first, pointed out that unless the antisocial attitude of the offender could be corrected during the term of imprisonment, he would again become a danger or at any rate a nuisance. He might be worse than before. Both the probation and the Borstal system had proved of great value. The policy in Scotland was to attempt to train the prisoner for citizenship. Training did not mean more comfort in the prison, but more effort by the prisoner—the building-up of character and self-respect. Mr. James Adair, procurator-fiscal, said that the courts could not

ROYAL BUCKINGHAMSHIRE HOSPITAL.—On Nov. 21st Mrs. Bernard laid the foundation-stone of the extensions to this institution. The committee is hoping to raise £50,000 for the extensions and £16,500 has been received. A new contributory scheme is being drawn up to give the hospital a continuous and regular income.

possibly wait until there had been the long examination necessary to decide how long the person was going to require for treatment or incarceration before he began to benefit. He thought it should be seriously considered whether all sentences should not be indeterminate. Such sentence having been pronounced, a committee of investigation should decide what was best for the particular prisoner. Sheriff-Principal Brown, K.C., referred to the distinction between the criminal and the delinquent. He spoke of the relief it would be if psychiatrists would say which were born bad and which had become so. Whatever the type of criminal, he always favoured kindness so far as that was possible with safety; but punishment was no use unless it hurt, and society had to be protected.

Dr. Angus MacNiven said that a person might be insane and yet perform a crime, know the nature of his act, and know that he was doing wrong. Whether he was guilty or not was a matter for the lawyers. Medical men could claim that once a person had been pronounced guilty, they should have something to say about treatment. He thought that they should be careful not to exaggerate the value of psychotherapy as a means of treating a criminal. Dr. W. R. D. Fairbairn described the present system as a failure. Short sentences were hopeless, and there was no place for prison at all unless the sentences were indeterminate. As a deterrent and reforming agency it was inefficient. What was important was research into the cause of crime. Dr. D. J. Forbes regarded high-grade mental defectives as a serious social danger.

IRELAND

(FROM OUR OWN CORRESPONDENT)

RESIGNATIONS IN THE SCHOOL OF PHYSIC

THE resignation of the dean of the faculty of physic, Dr. Andrew Francis Dixon, both from his post as dean and from the chair of anatomy in the University of Dublin, following closely on that of his colleague, Dr. Harold Pringle from the King's professorship of the institutes of medicine, has caused much regret to his colleagues, to his past and present pupils, and to the medical profession of Dublin. This regret is increased by the fact that in both cases the resignation has been brought about by reasons of health. Dixon, a pupil and assistant of Daniel John Cunningham, was professor of anatomy in Cardiff from 1897 to 1903, when he succeeded his old master in Dublin. Since then he has conducted the department of anatomy with ability and energy. For several years past he has also been dean of the faculty. He devoted himself to the interest of his pupils, kept in touch with them when they had gone out into the world, and was always the first to be visited when they returned to their old school. To his colleagues he was an elder brother whose wise counsel was sought and generously given whenever difficulties arose. Pringle was also a former student of the school in which he taught, having been a pupil of John Mallet Purser. He was appointed King's professor of the institutes of medicine in 1919, having held a lectureship in Edinburgh University for some years previously. He, too, was held in esteem and affection by his pupils and colleagues. It is unfortunate that the school of physic in Trinity College should be deprived of the heads of two of its important departments at the same moment. They carry with them to their retirement the affection and sympathy of all their colleagues and pupils.

PARIS

(FROM OUR OWN CORRESPONDENT)

THE FAMILY DOCTOR'S FORUM

THE "Assises de Médecine" is a movement started by Dr. Henri Godlewski for the pooling of medical observations by general practitioners throughout France, and not long ago he was able to tell the Academy of Medicine that his offspring has developed astonishingly since its birth in March, 1932. Already in April of the same year groups had been formed in a third of all the departments in France. The system adopted is to choose a certain subject some time in advance, to discuss it at local meetings, and then to submit the information thus collected to discussion at headquarters, at the Hôtel-Dieu in Paris. The first session of the "Assises de Médecine" dealt with rural tuberculosis and the means of combating it. The next subject was cancer houses. The subsequent subjects have been: regional clinical manifestations of alcoholism, the part played by domestic animals in human pathology, conjugal tuberculosis, the prevention of tetanus with serum, the prognosis in pleurisy, the incidence and present characteristics of syphilis, the prognosis in infantile convulsions, goitre in France, the present position of acute articular rheumatism, local dietetic customs, diphtheria, the prognosis in hyperpiesis, consanguinity and heredity, family predisposition to the localisation of disease, and the late results of lung collapse treatment. During the three years of its existence, the "Assises de Médecine" have held more than 500 scientific meetings. At every meeting at the Hôtel-Dieu a prize is awarded for the best scientific contribution; and the voting, which is secret, is usually unanimous in favour of the recipient of this prize. As Dr. Godlewski pointed out, the "Assises de Médecine" have done much to demonstrate the importance of the part played by the family doctor in preventive as well as in clinical medicine. It is the family doctor who can provide most information about the ultimate fate of the patient, particularly in those villages in which the medical succession is from father to son.

ROYAL DENTAL HOSPITAL

At this hospital's 26th annual clinical At Home, held last Saturday, a full and interesting programme had been arranged for the many visitors. The morning was devoted to demonstrations—surgical, orthodontic, and prosthetic. These included a routine operating session in the in-patient department of Charing Cross Hospital, with Mr. S. A. Ridett as operator and Dr. T. B. Vaile as anaesthetist, and operations under regional anaesthesia by Mr. S. F. St. J. Steadman in the Royal Dental Hospital. Mr. L. E. Claremont performed apical resection of teeth and Mr. H. L. Hardwick demonstrated the treatment of pyorrhoea by gingivectomy. A demonstration of orthodontic cases and their treatment was given by Miss K. C. Smyth, Mr. H. R. Evans, and Mr. J. H. Hovell. The complicated technique involved in the construction of porcelain jacket crowns was shown by Mr. W. I. Robertson, while Miss van Thal showed what can be done by speech training to children with cleft palate. The afternoon was devoted to clinical cases, and the hospital was filled almost to overflowing by old students and others. A large number of patients were present illustrating rare or instructive clinical conditions, such as cysts and tumours, supernumerary teeth, and deficiencies

in dentition. Others showed the results of various operations, some of which were remarkably good. Among them were examples of plastic surgery performed by Mr. T. P. Kilner in conjunction with members of the staff. One was a case of complete ankylosis of the jaws with an excellent functional result. Another had had an artificial sulcus made by means of an epithelial inlay which had enabled a lower denture to be worn with comfort and security. A series of patients for whom gingivectomy for pyorrhoea had been performed showed the value of this method in suitable cases. Several patients for whom students had made some beautiful porcelain jacket crowns were present; the work defied detection and reflected great credit both on the students and their teachers. There were also many children showing various forms of malocclusion both before and after treatment. Dr. Sydney Blackman exhibited a collection of radiograms so comprehensive that many visitors must have regretted that it could not be permanently on view at the hospital. He also gave a helpful lecture on conditions found in the apical maxillary incisor region and the technique which should be adopted to demonstrate this region radiographically. The John Hampton Hale research department was open, and the research workers, Messrs. Fish, Macgregor, Pincus, and Stewart-Ross, were present to explain the work on which they are engaged.

The annual dinner of past and present students was held at the Trocadero Restaurant on the same day with Mr. Herbert Smale in the chair and an attendance of over 150. The toast of the hospital and school was proposed by the chairman, who alluded to the honour which had befallen Dr. E. W. Fish who had been invited to give a course of lectures in Australia, and had received an honorary degree from the University of Sydney. Mr. H. Stobie, the dean, in his reply said that the school had increased in numbers, and the last entry was the best for many years. They welcomed on the staff Mr. B. W. Fickling, the third of his name to be associated with the hospital. The resignation of Miss Smyth from the post of orthodontic demonstrator was deeply regretted, for her services had been of great value. The number of students taking the B.D.S. was increasing, and it was hoped that now that the curriculum for this degree had been amended, more students would take a degree. The toast of the visitors was proposed by Mr. A. T. Pitts, and replied to by Colonel C. H. Howkins. Mr. F. Coleman proposed the toast of the chairman, which was drunk with musical honours.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. J. C. Kelly, D.S.C., to *Pembroke* for R.N.B.
Surg. Lt.-Comdr. W. A. Hopkins to *President* for course.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lts. E. G. Thomas and D. M. Craig to be Surg. Lt.-Comdrs.

W. I. D. Scott entered as Proby. Surg. Lt.
Surg. Sub-Lt. J. D. Lendrum to be Surg. Lt.
Proby. Surg. Lt. H. G. Rees to be Surg. Lt.
Proby. Surg. Sub-Lts. to be Surg. Sub-Lts.: M. D. Edwards, S. E. Cooke, and R. V. Jones.

ROYAL ARMY MEDICAL CORPS

Lt.-Cols. H. P. Hart, M.C., and T. T. H. Robinson, D.S.O., having attained the age for retirement, are placed on ret. pay.

Majs. E. Phillips, D.S.O., M.C., and S. D. Reid to be Lt.-Cols.

Short Service Commissions.—Lt. (on prob.) A. B. Dempsey is secd. under the provisions of Art. 213, Royal Warrant for Pay and Promotion, 1931. Oct. 28th, 1935.

SUPPLEMENTARY RESERVE OF OFFICERS

Capt. J. Morgan resigns his commn.
S. D. Loxton and W. H. Valentine to be Lts.

REGULAR ARMY RESERVE OF OFFICERS

Capt. I. S. Thomson, from the Supp. Res. of Off. R.A.M.C., to be Capt.

TERRITORIAL ARMY

Col. J. Taylor retires on account of ill-health and retains his rank, with permission to wear the prescribed uniform.

Cpts. T. J. C. MacDonald and F. Lishman resign their commns.

Lt. G. T. Pitts, from 97th (Kent Yeo.) Fd. Bde., R.A., to be Capt.

R. L. Harward (late Offr. Cadet, Univ. of Lond. Contgt. (Med. Unit), Sen. Div., O.T.C.) to be Lt.

The War Office announces that as a result of the conversion of seven infantry battalions of the 56th (1st London) and 47th (2nd London) Divisions to anti-aircraft units, the Army Council have decided to amalgamate these two divisions to form "The London Division," consisting of three infantry brigades and divisional troops. The headquarters of "The London Division" will be at Finsbury Barracks, City-road, E.C.1. The formation of the London Division will take effect from Dec. 15th, and its composition will be:—

1st (London) Infantry Brigade: Headquarters at Regimental Headquarters, Grenadier Guards, Birdcage-walk, S.W.1.

2nd (London) Infantry Brigade: Headquarters at Finsbury Barracks, City-road, E.C.1.

3rd (London) Infantry Brigade: Headquarters at Regimental Headquarters, Scots Guards, Birdcage-walk, S.W.1.

The Divisional Troops will include the Royal Army Medical Corps: 167th Field Ambulance, and the Army troops in the London Divisional Area will include the 13th General Hospital, 8th Hygiene Company.

ROYAL AIR FORCE

Wing Comdr. A. F. Rook to R.A.F. General Hospital, Palestine and Transjordan, Sarafand. For duty as Commanding Officer and Senior Medical Officer, Palestine and Transjordan, vice Wing Comdr. J. Rothwell.

Squadron Leader J. D'I. Rear to R.A.F. General Hospital, Hinaidi, Iraq, for duty as Medical Officer.

Flight Lts. J. S. Carslaw to Aircraft Depot, Karachi, India; R. E. W. Fisher to No. 31 (A.C.) Squadron, Karachi, India; and H. F. Harvey to No. 5 (Army Coöperation) Squadron, Chaklala, India.

Dental Branch.—Flight Lt. Roy Herbert Marthews to R.A.F. General Hospital, Hinaidi, Iraq. (Substituted for notice in THE LANCET last week.)

INDIAN MEDICAL SERVICE

Col. E. W. C. Bradfield, C.I.E., O.B.E., V.H.S., to be Maj.-Gen.

Lt.-Col. N. S. Sodhi, M.C., to be Col.

Examination for the F.R.C.S. in India.—At the request of the Director-General, I.M.S., the Council of the Royal College of Surgeons of England will again conduct the primary examination for the F.R.C.S. in India.

The examination, which will begin on Dec. 19th, is to be conducted at the Medical College, Calcutta, and 67 candidates have entered. The Royal College is sending out two examiners.

The anatomy examiner will be Mr. G. Gordon-Taylor, and he will be accompanied by Mr. H. H. Rew, director of examinations. Mr. L. M. Banerji, professor of surgery at Calcutta University, will be Mr. Gordon-Taylor's assessor. The examiner in physiology will be Dr. G. A. Buckmaster, emeritus professor of physiology in the University of Bristol. Capt. B. T. Krishnan, professor of physiology at Madras University, will act as his assessor.

DEATHS IN THE SERVICES

The death occurred on Nov. 22nd in London of Lt.-Col. EDWARD MAIR, I.M.S., retd. He was born in 1847 and joined the Service in March, 1874, was employed on military duty and in acting civil appointments till January, 1879, when he was appointed civil surgeon, Bijoor. He became jail superintendent at Jhansi and Benares, and in 1891 superintendent to the central jail at Bareilly. He acted as Inspector-General of Jails for North West Province in 1892 and for Bengal in 1898. He reached the rank of lieutenant-colonel in 1894 and retired in 1902.

GENERAL MEDICAL COUNCIL

PRESIDENT'S ADDRESS

At the opening of the 142nd session of the Council Sir Norman Walker began his presidential address by welcoming representatives of the Universities of Liverpool and Bristol in the persons of Mr. R. E. Kelly and Prof. R. J. Brocklehurst, who succeeded Prof. J. M. Beattie and Prof. E. Fawcett, a surgeon and a physiologist taking the places of a pathologist and an anatomist. He went on to say that the Lord President of the Council had approved in principle the proposal of an amending Bill to deal with (1) the election of direct representatives, (2) the recognition of public health diplomas granted other than in the United Kingdom, and (3) the publication of the British Pharmacopœia. Difficulties under the first heading did not press, since in normal course there would be no election before the autumn of 1938.

A Survey of Medical Education and Legislation

A number of the bodies and medical schools to which the interim report of the Curriculum Committee was circulated early in June had, said the President, sent in replies, but the majority desired more time to formulate their views. The replies were generally helpful and constructive. He would take the opportunity offered briefly to survey the position of medical education and legislation in this country, and particularly the relations of the Council to it.

During the earlier years of the nineteenth century there were many efforts to secure some better regulation of the practice of medicine, for it had become evident that something different from the limited rights and privileges conferred by Royal Charter, or by existing Acts of Parliament, on universities and medical corporations was required. In 1834 a committee of the House of Commons was appointed to inquire into the state of medical education and practice. This committee stated that "to produce some approach to uniformity there should be some superintending body to take cognisance of the manner in which the duty of examining is conducted."

In 1842 Sir James Graham, principal secretary of state for home affairs, circulated to the chartered medical bodies a printed paper containing the heads of a Bill proposed to be brought into Parliament for regulating the state of the medical profession throughout all parts of the United Kingdom. The census return of that date showed that there were about 34,000 persons practising one or more branches of medicine, and it was estimated that not more than 11,000 of these were "qualified." In the same year, Sir Robert Christison suggested the establishment of a Central Council of Health, consisting of H.M. principal secretaries of state, four persons, not professional, appointed by H.M. in Council, two from England, one each from Scotland and Ireland, and six representatives from the corporations and universities. It was clear that in the eighteen-forties and -fifties a good deal was going on behind the scenes, one section of opinion being in favour of a central body largely composed of laymen, in close relationship to the Government, another standing firm for the maintenance of the rights and privileges conferred on universities and colleges by Royal Charter or by legislative action (e.g., the Apothecaries Act, 1815) in many instances dating back hundreds of years. Nearly every session of Parliament from 1840 to 1868 saw the introduction of some Bill intended to establish a central medical authority which might undertake or supervise the urgently needed reforms.

THE 1858 ACT

No secret documents, said Sir Norman, had been found among the Council's papers, and all those

concerned were long dead, but the Medical Act, 1858, was, he surmised, in a sense an expression of the influence and status of the Chartered Bodies, and resulted in the establishment of a Council with rather vague and undefined powers, composed of one member from each of the Chartered Bodies, together with six members nominated by the Crown, with the Privy Council in the background. Sir John Simon had described the first Council as "a first timid experiment of the Legislature," adding that the powers of control given to it were far too small.

The preamble to the 1858 Act was clear enough about its object, but it was left to the Council to define what was a qualified practitioner. They began their work with great zeal, and first settled certain points regarding admission to the Register under Section 46. This section gave the Council authority to admit to the Register, in addition to those who held diplomas from any of the bodies named in Schedule (A) to the Act, and certain holders of foreign or colonial qualifications who were practising in the United Kingdom before the passing of the Act, any persons who had held appointments as surgeons or assistant surgeons in public services or charitable institutions, and also, so far as to the Council might seem expedient, medical students who had commenced their professional studies before the passing of the Act. They next turned attention to the British Pharmacopœia, and made arrangements for its production, and then at their fifth meeting, on Nov. 27th, 1858, they applied to all the bodies named in Schedule (A) for a statement (under Section 18 of the Act) of the courses of study and examinations to be gone through in order to obtain their respective qualifications.

A LOW STANDARD

At the second session, on August 3rd, 1859, the first committee on education was elected. The Council's first volume of minutes registered the opinion that the general education of the medical student should be controlled by national bodies (by which they meant the Government and the universities) and not directly by the newly established Council of Medical Education. There was abundant evidence that the prevailing standard left much to be desired, and the comments of the Admiralty on the low standard reached by some of the candidates for commissions in the Navy were candid and caustic. The returns for 1865, referring to twenty-one candidates, recorded that five candidates were utterly ignorant of Latin, the Latin of one was bad, while another was deficient in anatomy, surgery, and Latin. Five passed an indifferent examination, the manuscripts of four were indifferent or bad, and only four passed a good, and two a moderately good, examination. It had to be borne in mind that at that time admission to the new Medical Register was easy, and anyone who could show that he had held a medical appointment of any kind might be admitted.

As an example of the deep concern of the Council for education, Sir Norman recalled that on April 25th, 1864, the Council, after discussing routine business, resolved itself into a committee on education, and occupied seven of the twelve days of the session in discussing it. It was then decided (1) that the course of study was to be not less than four winter sessions, or three winter and two summer sessions; and evidence was to be produced that the remaining period of the four years had been spent in the acquisition of professional knowledge; (2) to view with approbation any encouragement held out by

the licensing bodies to students to prosecute the study of the natural sciences before they engaged in studies of a strictly professional character; (3) to recommend that the first examination be conducted partly in writing and partly *viva voce*, and that the second (final) examination be conducted partly in writing, partly *viva voce*, and as far as might be convenient and practicable, clinically.

AN ABORTIVE AMENDING BILL

In the minutes for 1874 appeared a draft of a proposed Bill to amend the Act of 1858 to the effect that no one should be entitled to be registered unless he was qualified both in medicine and in surgery, including midwifery. But the Bill contained more than that. There appeared in it for the first time the proposal that no registered practitioner should be entitled to hold any sort of official appointment unless, in addition to being duly qualified and registered (as was already required under Section 36 of the Act of 1858), he had also been examined and declared competent for such appointment by an examining board to be constituted under the Bill, and thereby entitled to append to his name on the Register the letters C.M.B., signifying Civil Medical Board. Three months after the passing of this Act, it was to be the duty of the General Medical Council to appoint a Civil Medical Board, consisting of five examiners from England, five from Ireland, and five from Scotland, whose duty it would be to examine all candidates presenting themselves, who were to have passed the double examination in medicine and surgery. A motion to approve this draft Bill was negatived by nineteen to two, three members not voting.

ROYAL COMMISSION OF 1880

In the years 1870-1881 no fewer than twenty Bills were brought in by private Members, in addition to three or four by the Government. The suggestion of a common Board of Examiners, or of three National Boards, had evidently made a strong appeal to some of the Parliamentary reformers; for more than half of the Bills presented contained provision for the establishment of such examining boards. In the 'seventies the Government of the day made at least three serious efforts at medical legislation, each of which was hampered by the opposition of some section of the medical profession. In 1880 the Government decided to refer the whole matter of amendment of the Medical Acts to a Royal Commission under the chairmanship of the Earl of Camperdown, which numbered amongst its membership the Bishop of Peterborough, the Master of the Rolls, Sir William Jenner, John Simon, T. H. Huxley, William Turner, and James (afterwards Viscount) Bryce.

The Royal Commission took evidence on 22 days, and examined 41 witnesses. They recommended the establishment of three divisional boards consisting of representatives from all the medical authorities in England, in Scotland, and in Ireland, each of which was to be responsible for conducting the only examination which would afford access to the Medical Register. The Council, which was to consist of 18 members (6 nominated by the Crown, 4 direct representatives (2 for England and 1 each for Scotland and Ireland) and 8 members to be chosen by the Divisional Boards (4 for England and 2 each for Scotland and Ireland)) was to have a general control over the divisional boards. The Medical Council was to be the sole licensing authority, and was to take proper steps to ensure, as far as possible, equality in curriculum and examination between the three divisional boards. To the divisional boards was to be entrusted the registration of students, and the full period of study was to be subsequent to registration.

THE 1886 ACT

It may well be asked, said Sir Norman, how is it that in the light of this report the 1886 Act is what it is? The explanation might be found in the text of the report itself. It was true that all the eleven members of the Commission signed the report as a whole, but to six of the eleven names was affixed an asterisk, directing attention to subjoined memoranda by the Bishop of Peterborough, Mr. Slater-Booth, John Simon, T. H. Huxley, William Turner, and James Bryce, expressing diversity of opinion on detail. In addition to their individual memoranda, John Simon and William Turner contributed a joint one.

The 1886 Act may not have been perfect from the medical point of view, but it established several new principles. No one could now be registered who had not passed a qualifying examination in medicine, surgery, and midwifery, and the system of approximately decennial inspections which it introduced was of equal value to the public and to this Council. Part II. of the Act greatly simplified the problem of colonial and foreign practitioners, and the first section of Part III. provided that if the G.M.C. failed in the discharge of its duties, the Privy Council might act in default. The same part also provided for the registration of diplomas in sanitary science, which to-day occupied so important a place in public health administration. It was a testimony to the effective results of the Act that whereas numbers of Acts were passed and Bills introduced to amend the 1858 Act, the Act of 1886 had remained almost untouched. Indeed since 1886 the Acts placed on record in the Medical Register were limited to six recognising the establishment of six new Universities, three Midwives Acts, the Dentists Act, 1921, and two Acts to meet certain difficulties in Ireland.

CONCLUSION

In almost all other countries, said the President, medical education was controlled more or less directly by the State; on this Council every licensing body had its representative to contribute his share to the consideration of every proposed change in medical education. Their duty was to ensure "that the standard required from candidates at the qualifying examinations shall be such as sufficiently to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery." The standard had steadily risen, and to-day was very different from that of 1886, largely owing to the action of those bodies who, not being satisfied with the minimum of a former day, devoted themselves to making their own qualifications better and more in accord with current knowledge. At intervals, as they were doing now, the Council carefully explored the position and set forth in resolutions and recommendations the nature and extent of the training they deemed to be "requisite." The elasticity of the system was one of its strongest characteristics. "We place efficiency," said Sir Norman, "before uniformity, and we have learned by the experience of seventy-seven years that sound reason is more effective than compulsion."

The customary vote of thanks to the President was proposed by Sir Farquhar Buzzard and seconded by Dr. E. K. le Fleming.

Two names were restored to the Dentists Register: Arthur Leonard Heath and James Alexander Randolph Allison. The Council then passed to the consideration of disciplinary cases.

POST-GRADUATE LECTURES

DURING the past few weeks we have published extracts from, or abstracts of, thirteen lectures given to post-graduates at autumn courses in the London teaching schools. The series ends with a fourteenth, delivered by Dr. Vilvandré to former students of the London Hospital.

RESULTS OF X RAY TREATMENT

(DR. G. E. VILVANDRÉ)

THIS lecture is addressed to those of you who may not have much experience in X ray treatment, or to those who have not thought it worth consideration. I have for many years tried to take a common-sense view of the subject, to stand aloof sometimes; and although I use X rays for treatment my aim is to speak without bias.

For many years Röntgen rays of short wavelength have been largely employed in treatment, but the valuable properties of long waves have not been neglected, especially by men of experience.

Acne vulgaris is a condition which does not always respond well to the usual skin applications nor to vaccine therapy, and in such cases X ray treatment in small doses has brought not only improvement but nearly always cure. A series of three treatments at a few weeks' interval has been the usual procedure. In *psoriasis* again, X rays will often benefit the patient and cause disappearance of the lesion, though they do not cure the disease. Here one must remember that prolonged treatment is inadvisable. Skin irritation is another troublesome condition that will often respond favourably; patients with pruritus vulvæ and pruritus ani may get much relief from a small dose or two; but here, of course, the underlying cause must always be sought as well.

Before leaving the skin I must also just mention *lupus vulgaris*, but only to warn you against the employment of X rays here. The skin clinic of the London Hospital contains numerous photographs of cases of lupus treated elsewhere in years gone by in which repeated application of small doses has led to epithelioma. For the same reason treatment of hirsute women should be left alone. The result of applying X rays for *hypertrichiosis*, whether facial or axillary, has been the development of telangiectases; and even X ray dermatitis might follow frequent or prolonged repeated applications. Once women have seen the effect of epilation they are only too anxious to have it repeated, and the only safe thing is not to start the treatment at all. So-called beauty parlours use this method to the danger of the public.

Before radium was seriously thought of, the London Hospital, under the guidance of Dr. Sequeira, was curing rodent ulcers with X rays; and the rodent ulcers of our younger days were usually of large size, having either been undiagnosed or else treated by remedies anything but beneficial. Rodent ulcers when removed surgically tend to recur in the scar, and radiation is always desirable after operation. Radium treatment, especially in the smaller lesions, often yields excellent results, but I have known heavy doses of X rays cure when radium has failed. Ten or twelve years ago I was also treating successfully big fast-growing facial nævi with X rays.

A man had carcinoma of the skin of his neck and sections were cut and the diagnosis definitely established. He received X ray treatment at my hands quite five

years ago and so far has shown no recurrence. I have kept in touch with him and my last interview was to examine his gall-bladder in which I found gall-stones. They were subsequently removed but his illness obviously had no connexion with the carcinoma of the neck and he is now quite well.

Now let us pass on to deeper structures.

The glands of *lymphadenoma*, whether of the neck or the abdomen or groin, respond readily to X rays and usually within two or three weeks a mass of glands will shrink when subjected to proper rays and filtration. One has to remember, however, that different forms of apparatus are needed to produce different kinds of rays; and let me add here that the possession of an X ray apparatus does not make a radiologist. Further, the different filtration of X rays leads to different results. In these days mathematically accurate dosage can be given.

Masses of glands (*lymphadenomatous masses*) at the hilum, sometimes involving one-third of the thorax, will disappear under treatment; but—and this is unfortunately an important “but”—X rays do not cure the disease. They make the patient comfortable, they relieve his dyspnoea and pain from pressure; but Hodgkin's disease goes on until bones or liver or kidneys are invaded. I often say that we have doubled the life of the Hodgkin's patient: before X rays they lasted two years; now we see patients alive four years and occasionally seven or eight years after the onset. Where anæmia is severe it is sometimes useful to give blood transfusions in conjunction with irradiation.

Sometimes real benefit will follow X ray treatment of large tuberculous glands in the neck, provided they are not caseous; but of course you cannot expect good results in a tuberculous patient whose home conditions are next door to starvation.

X ray therapy will reduce the size of an enlarged spleen but not cure the *myelogenous leukaemia* of which the patient is suffering; it will make him comfortable. When employed in the treatment of *actinomycosis*, where sinuses or inflamed masses (sometimes looked upon as cancerous) are present, real benefit will often follow; the sinuses dry up and the masses shrink.

Before coming to the wide use of X rays for carcinoma I may mention a case of *sarcoma* of the left sacro-iliac region which was operated upon and found to be irremovable eleven years ago. In those days we only had medium X ray therapy in use, but subsequently deep therapy came in and was employed with such effect that the patient is alive and working to-day. Similarly *mediastinal tumours* will sometimes disappear, certainly for years, after using “deep” X rays (short waves) given through several ports of entry. A spectacular, amazing result.

Real success has followed treatment of carcinoma of the thyroid, where a large mass, indurated and accompanied by malignant glands, is present. Even in cases where one or more secondary deposits have been evident in the lungs retrogression and even disappearance of the carcinoma has followed deep therapy. I am so convinced of its value in this particular disease that if I were unfortunate enough to fall a victim it would be my choice of treatment and I would be optimistic about the result.

On the other hand I have obtained bad results in *carcinoma of the antrum* or of the jaw. I have seen equally bad results with radium treatment, but I am not here to discuss radium treatment.

How far the presence of chronic sepsis in these regions is responsible for the failure I cannot say.

You will be told, or you may have read, from time to time that *carcinoma of the bronchus* is treated by deep therapy, but really the results have not been at all satisfactory. Personally I have seen no real improvement; although in one or two cases I have thought the patient was getting some benefit, the end has always been the same. The same applies to treatment of carcinoma of the oesophagus. Here some extravagant claims have been made, but in actual fact deep therapy has not been a success. At the same time we must beware of making too general a statement about the failure of X ray treatment, for two patients with carcinoma never behave alike.

More satisfactory have been the results with *carcinoma of the larynx*. Here the comparative superficial position of the neoplasm has rendered treatment more effective and both in France and in this country cures have been claimed; the treatment often results in the destruction of the thyroid cartilages, but that is perhaps a minor evil. At the London Hospital I have mostly had to deal with large masses of hard malignant glands in the neck, which are sent for deep therapy after a diagnosis of carcinoma in the upper air-passages or at some primary site not ascertained. But although I have often seen glands get smaller I have never been able to eliminate the disease; and personally I think it is rather a waste of time to treat large masses of carcinomatous glands in the neck.

Whereas I am never inclined to take on for treatment a case of malignant disease of the throat, tongue, pharynx, or larynx I never hesitate to welcome a case of *carcinoma of the breast*. I have come to the conclusion that I can always do some good in these cases. Many years ago with apparatus which was vastly different to that of to-day I had two striking cases, one in a woman of 65 and the other in a woman of 44.

The patient of 65 had a somewhat scirrhus type of carcinoma and after comparatively little treatment the whole thing disappeared, clinically. That it was not a case of mastitis was confirmed eight years later when the patient developed, in the same breast and in about the same region, a recurrence of the neoplasm. She died fairly soon after this but for eight years she had had no treatment and during that time there was no evidence of carcinoma of the breast.

The other case was more remarkable: it was an obvious carcinoma en peau d'orange. It was growing rapidly and glands in the axilla were invaded and she was sent to me by the surgeon as inoperable with the request for treatment. To my surprise and joy the whole thing cleared up after some months. This was eleven years ago, and I followed the case until two years ago when the patient was still well and in charge of a large department. She was in quite good health and there was no evidence of recurrence of the former trouble.

These are, of course, remarkable cases, and they are not usual results, but we must remember that the greater number of breast cases that come to the radiologist are inoperable or post-operative. Most of the post-operative cases which I am asked to treat are such as have developed recurrences either in the scar or in the glands of the supraclavicular region or the axilla. Others I am called upon to treat are people whose arm shows extensive oedema from pressure of malignant masses situated deeply in the axilla or the neck, or even as the result of secondaries in the chest; and although the outlook here seems hopeless a great deal of good can be done to some of the patients.

One patient had an inoperable scirrhus carcinoma of the breast with a great deal of induration and retraction of the nipple. The arm was painful because of its weight, and cumbersome. As the result of treatment, started about eighteen months ago, the arm has now reached almost normal size and the carcinoma, except for the scar, is not palpable. Where the best part of the breast was hard it has become soft and I think that the patient will live a good many years in comparative comfort.

In an inquiry made in 1931 I found that of the breast cases which received post-operative radiation to prevent recurrences about 25 per cent. were alive at the fourth year from starting X ray treatment. Not all of these were sent directly after operation. At ten years from operation the best figures obtained were 7 per cent. Such cases had been treated with a kilovoltage round about 100 with Coolidge tubes and filters of 4-6 mm. of aluminium, mostly the former. Some of the earliest cases which had remained alive many years exhibited damage, such as erosion of a costal cartilage. Telangiectases were extensive in some, but the patients had been alive 11 or 13 years after operation and had carried on their daily occupation. In none of them have I ever seen anything of a severe anaemia; nor to my knowledge has any patient I have ever treated with X rays developed an aplastic anaemia. My assistant O'Doherty and I took 12 cases of carcinoma which had received X ray treatment at 180 k.v., 4 m.a., and 0.5 or 1 mm. of copper and 2 mm. of aluminium for periods of one, two, and even three years, and found that in none of them was there anything of a severe anaemia, although they each had received many thousands of r units. The blood counts were made in the clinical laboratory of the London Hospital. Whatever radium may do as regards aplastic anaemia I have never seen really adverse blood changes from X rays. On the other hand, some subjects receiving prolonged doses have obviously improved in haemoglobin and red blood corpuscles even under X ray treatment when given iron and arsenic.

When inoperable carcinoma is present and subjected to X radiation the technique used will depend on the size of the breast and its firmness or otherwise. Tangential radiations may be used. I am not, however, prepared to place too much importance upon the damage said to be done by X rays to the lungs and pleura underlying the affected breast. Healthy tissues fortunately have the power to withstand big doses of radiation and probably some of the bad effects mentioned should be ascribed to secondary deposits in the pleura. The removal by operation of recurrences either of secondary glands or nodules is to be deprecated since it often causes general spread.

Among other conditions for which X ray treatment has been beneficial is *mastitis*, and I have also obtained really encouraging results in inoperable *carcinoma of the ovary*. In one case especially where the peritoneum was studded with secondary deposits the patient six months afterwards looks well and lives a happy life.

Lastly, X ray therapy is often useful in cases of *fibroids* and *metrorrhagia*. After a few doses a woman leading a useless invalid life, often blanched and without strength, will gradually recover good health and will be ever grateful for relief obtained without the mental anguish, pain, or fear sometimes associated with operation. Cases should, of course, be carefully selected and the decision reached upon the opinion of a physician or gynaecologist and the radiologist.

OBITUARY

DAN MCKENZIE, M.D. Glasg., F.R.C.S. Edin.

Dr. Dan McKenzie, who died at his home in Hampstead-lane on Nov. 19th at the age of nearly 66 years, was a well-known laryngologist and made a mark on his contemporaries by his forceful and resolute character. Daniel McKenzie was the son of William Stewart McKenzie, general practitioner and health officer at Larkhall, Lanarkshire, and was born there in January, 1870. He was educated at the local academies and at the Glasgow School, taking his medical course at Glasgow where he was medallist in several clinical subjects. After qualifying in 1891 he joined his father in practice in his native town where

DR. DAN MCKENZIE

(Photograph by Elliott & Fry)

he was parochial medical officer and certifying factory surgeon, and where he made a study of rheumatism and endemic goitre. At this time he married Dora Christine, second daughter of Sir John Benjamin Stone, scientist and traveller. Shortly after their marriage McKenzie moved south and settled at Leytonstone, still in general practice, although his interests were already turning in the direction of

laryngology. He became laryngologist to the Ilford Emergency Hospital and in 1906 restricted his practice to diseases of the nose and throat on appointment to the staff of the Central London Throat and Ear Hospital. He was then lecturing on otology at the Medical Graduate College. He took the F.R.C.S. Edin. in 1909 and became editor of the *Journal of Laryngology* two years later, finding time also to write on many aspects of his subject in the weekly medical journals. He translated Onodi's book on the Lacrymal Organs and brought out a little guide of his own to diagnosis in diseases of the throat, nose, and ear. Later he embodied the fruits of his experience in two large volumes entitled "Diseases of the Nose and Ear" (1921) which differed from other text-books by its more liberal construction of the sphere of the laryngologist. In his professional work he was broad-minded and rational, tolerant of new ideas, and ever ready to listen to the arguments of others.

Dan McKenzie was before everything a scholar and a poet. His mind was stored with great knowledge of history, folk-lore, especially the history of medicine, and at the same time attuned to rhythm and the beauty of words. These gifts he put freely at the disposal of one great cause. Long before the modern anti-noise movement began he had written "The City of Din," a tirade against noise which reads as though it was part of the most modern propaganda. The din in which dwellers in large cities are obliged to live would, he held, shatter the strongest nerves if a certain tolerance were not bred by habituation, and he hinted at the possible development of pro-

fective deafness in the men of the future. Thirteen years later McKenzie lectured for the Chadwick Trust on noise in relation to public health, in which he castigated unnecessary noise not only in the streets but inside the hospitals, which he thought hindered the recovery of the sick, and he appealed to hospital authorities to look into this matter with their nursing staffs. After this he naturally took his place as one of the founders of the Anti-Noise League.

A colleague writes: "The world is poorer by the death of Dr. Dan McKenzie who, while deservedly prominent in the active world of medicine, enriched the circle in which he revolved by his studies in social, legendary, and literary lore, while he adorned it in special by an outflow of poetry—sweet, sonorous, and essentially spontaneous. He was wonderfully alive to the suffering of his fellow men from the increasing amount of noise to which they were exposed, giving to it bright and essentially readable expression in 'The City of Din,' and using his remarkable power of declamatory utterance in the crusade against noise. His pen was that of a ready writer and, when employed on the subjects nearest to his heart, wielded a virile and persuasive phraseology. His essay on smell and the olfactory organs was issued under the euphonious title of 'Aromatics.' His poetic faculties found vent in various forms such as a little volume of love-lyrics entitled 'Romantics' and a number of tender effusions in broad Scots. McKenzie was an effective debater and with his commanding figure and powerful voice he was always able to gain an attentive hearing, and seldom failed to carry conviction. As a teacher he was superb and in his hospital work indefatigable. In his earlier days a little autocratic and apt to excite the antipathy of those under him, he became well loved and esteemed by colleagues, nursing staff, and, above all, by the humble sufferers in whose interest he never spared himself. His was certainly a remarkable character and occasional eccentricities of manner were far outweighed by the genial warmth of his disposition. Kindly, humorous, tolerant, it will be long before he is forgotten by his friends."

Dr. McKenzie is survived by his widow, one son, and one daughter.

ALFRED CUMMING GRANT, M.B. Glasg.

ON Nov. 18th there died in London Alfred Alexander Cumming Grant, who for many years had worked as a general practitioner in Soho and neighbourhood. His wide interests were reflected in the diversity of organisations to which he was official medical adviser: he acted as physician to a number of hotels, a chain of theatres, the central Y.M.C.A., a Catholic boys' school, several Jewish societies, and referee to a number of insurance companies. Born in 1852, he was third of the six sons of John Grant, crofter of Drumnadrochit in Glen Urquhart, and when he was about twenty he went to Glasgow where he supported himself by working in a drapery warehouse while studying first for his matriculation and later for his medical qualification. In 1894 he graduated as M.B., and thereafter was house surgeon at the Glasgow Maternity Hospital. After a period of private practice in Govan and several voyages to India as medical officer on ships of the Clan Line he came to London to set up the practice from which he retired only about three years ago. To all his patients he gave much, and from his poorer ones at

any rate he was rarely willing to receive anything. His own early life had made him sensitive to the difficulties of the poor, for his sympathy was both generous and practical. Dr. Grant was active in many of the Scottish societies in London and was chief of the Gaelic Society. His fine presence

marked him out as a man exceptional among his fellows.

Dr. Grant married Miss Alice Saunders who died some years ago. A funeral service for him was held at Crown Court Church, Drury-lane, and his ashes were sent back to the glen.

CORRESPONDENCE

'CONTRACEPTIVE METHODS

To the Editor of THE LANCET

SIR,—In July, 1934, the National Birth Control Association set up a subcommittee consisting of qualified medical men and women, most of whom are experienced in giving birth control instruction in clinics and in private practice. This committee, having analysed replies to a questionnaire which was sent to doctors throughout the country, and made an intensive study of the investigations that are being carried out by scientific workers on the chemical and biological aspects of contraception, has arrived at certain conclusions which may perhaps be of interest to your readers.

In the first place, there is a general consensus of opinion that to obtain maximum security against undesired pregnancy reliance should be placed on a combination of contraceptive methods rather than on any single device. Briefly, the combination should consist of (a) a mechanical barrier—a sheath or rubber pessary—between the semen and the cervix, and (b) a spermicidal agent. In view of the fact that rubber is damaged by fats, particularly by vaseline, non-fatty vehicles should be used for the spermicidal agents. Furthermore, as rubber is affected by heat, light, and time, all contraceptives should be kept cool and in the dark, and marked with the date of manufacture, and preferably also with the date beyond which they should not be used. A gelatin base is preferable for suppositories. Foaming tablets are not always reliable, as they depend for solution upon the vaginal moisture, the amount of which may vary within very wide limits. There is considerable evidence that quinine and Chinosol (oxy-quinoline sulphate) are unsatisfactory spermicides, and that they can act as local irritants. Their use as chemical contraceptives has in some cases been followed by constitutional toxic symptoms.

In view of the extravagant claims made by some manufacturers of contraceptives in their advertisements, the subcommittee wishes to emphasise the fact that no chemical contraceptive at present available offers as high an expectation of success as the combination of methods mentioned above.

There are now about a hundred birth control clinics (either voluntary or municipal) in the United Kingdom, and nearly all the medical officers of these have gained their experience in the first place by attendances at other clinics. If the instruction is expert, sufficient medical training can be obtained by attendances at one demonstration or lecture and three or four clinical sessions. For many practitioners, such an extended course may not be practicable, but those who wish to increase their knowledge of contraceptive technique can obtain names of publications intended for the general practitioner, and also particulars of training, demonstrations, and lectures, from the National Birth Control Association, 26, Eccleston-street, London, S.W.1.

In conclusion, the subcommittee wishes me to state that the data on which the opinions expressed

in this letter are based are available to any medical practitioner on application to the National Birth Control Association, which would for its part welcome information from practitioners as to their own experience.—I am, Sir, yours faithfully,

M. A. PYKE,

Secretary, National Birth Control Association.

Nov. 22nd.

PUERPERAL PYREXIA

To the Editor of THE LANCET

SIR,—If I read aright your article on puerperal pyrexia in your issue of Nov. 9th (p. 1087) you appear to infer in the last paragraph of the article that the medical officer of health of an autonomous area for maternity and child welfare need not send a copy of the notification of puerperal fever and pyrexia to the medical officer of health for the county. In my opinion, such an inference is wrong, because Article 5 of the Public Health (Notification of Puerperal Fever and Puerperal Pyrexia) Regulations, 1926, leaves no such loophole and intends that copies of all notifications shall be sent to the county medical officer of health—except, of course, in the case of county boroughs.

I am, Sir, yours faithfully,

A. T. POWELL,

Nov. 18th. Medical Officer of Health, Walthamstow.

* * * The smaller authorities for maternity and child welfare often are glad to delegate to the county authority the inspection of their midwives and notification of puerperal fever to the same authority is then essential. But the autonomous authorities are (with the exception of the county boroughs) also obliged to notify to the county authority, even though they inspect their own midwives and deal with their own cases of puerperal fever. The inference in the article that autonomous areas need not forward notifications to the county medical officer was not intended, and we are grateful to Dr. Powell for making the point clear.—ED. L.

MISSION HOSPITALS AT QUETTA.—The Church Missionary Society Hospital and the Church of England Missionary Zenana Hospital at Quetta were both destroyed in the earthquake and an appeal is being made for funds for the erection of a joint hospital. The societies have already collected nearly £4000, but £15,000 is needed.

HOSPITAL SAVING ASSOCIATION: ANNUAL REPORT. The number of contributors to this association has increased during the year by 162,781 and its income by £96,007. In the thirteenth annual report it is stated that the total distributions out of the year's income will bring payments made for hospital services up to the total of £3,574,781. The amount of contributions paid in was £844,429 and 409,192 contributors and dependents were treated at voluntary hospitals. The management expenses come to just over 7 per cent. of the contributions and the sum of £46,353 is available for final distribution to co-operating hospitals. With £5000 added from the reserve fund the total payment for hospital services during the year will be £642,552.

MEDICAL NEWS

University of Oxford

Next June an election will be made to the Schorstein research fellowship in medical science, which will be able for two years in any of the medical departments Oxford. Candidates must be graduates of the University holding a registrable medical qualification and must be under 35 years of age on Oct. 1st, 1936. Applications should reach the dean of the school of medicine, University Museum, not later than May 4th.

University of London

At a meeting of the senate held on Nov. 20th Mr. Eric Boyland, Ph.D., was appointed to a readership in biochemistry at the Cancer Hospital (Free), and Dr. V. B. Wigglesworth to a readership in entomology at the London School of Hygiene and Tropical Medicine.

Dr. Boyland, who was born in 1905, is a graduate of the University of Manchester, where he obtained his B.Sc. degree with first-class honours in applied chemistry in 1926, later proceeding to the M.Sc. and Ph.D. He held a Beit fellowship from 1929 until 1931, when he became physiological chemist at the research institute of the Cancer Hospital. His work includes observations in collaboration with Mrs. Boyland on the enzymes and metabolic activity of normal and cancer tissue, and his recent observations are summarised in the recent report of the British Empire Cancer Campaign.

Dr. Wigglesworth, who is 36 years of age, was educated at Epton and saw service in France in 1917-18. Entering Caius College, Cambridge, he was elected a scholar in 1921, and in the same year graduated B.A. In 1922 he was awarded the Rank Smart studentship, and till 1924 carried out work for the Board of Scientific and Industrial Research in the department of biochemistry of the University. In 1926 he graduated B.Chir., and in 1929 was awarded the Raymond Horton prize for his M.D. thesis. Since 1926 he has been lecturer and Milner research fellow in medical entomology at the London School of Hygiene and Tropical Medicine. He has published numerous papers and contributed a volume on insect physiology to Methuen's monographs on biological subjects.

Society of Medical Officers of Health

The Minister of Health and the late Chief Medical Officer to the Ministry sat on one or other side of Dr. W. G. Savage at the annual dinner of the Society of Medical Officers of Health on Nov. 22nd. Sir Kingsley Wood had been confirmed that day in his office of Minister and as speaking to his regional medical staff of plans for the future. Sir George Newman, revisiting the Society after an interval of 28 years, was summing up the story of his own endeavour as first medical officer to a united national health authority.

Sir Kingsley, in proposing the toast of The Society, coupled with the name of its president, Dr. Savage, said how glad he was to return to the Ministry of Health after his sojourn among the hills of Mount Pleasant, speaking of the growth of public health services in the last ten years he paid tribute to the work done by medical officers of health, especially in the maternity, child welfare, and tuberculosis services. He could rely, he knew, on the cordial co-operation of the Society in tackling the two most urgent public health problems of the day—maternal mortality and cancer, while he also looked forward to continued development of maternity and child welfare services, the encouragement of nursery schools, and an extension of the school medical service. Dr. Savage, in reply, admitted that the Society always endeavoured to stimulate the Ministry of Health. But their aim to promote the advance of public health in every branch was becoming increasingly difficult; to-day the perfect medical officer must be at once doctor, statistician, chemist, architect, pathologist, and popular lecturer. Would Sir Kingsley perhaps make a Golden Voice an additional condition of service?

Dr. G. F. Buchan proposed the health of Sir George Newman as colleague and friend. He praised his qualities as administrator, historian, master of English prose, and pioneer of preventive medicine, and hoped that his retirement would be one from which he would frequently emerge. In reply, Sir George said he was an exile returning to a society which he had joined 40 years ago. He thanked them for asking him to be their guest and remarked that the best reward of the public health worker was the approval of his colleagues. He spoke of early days at Whitehall when Sir Robert Morant, to whose work for the service he paid a tribute, had first instructed him in

the duties of a civil servant. He had taught him that as a medical officer of health he might do a score of things, but when he entered His Majesty's service he must follow the hidden pathway of the silent life. The reward of the civil servant's work would be not higher wages but more work. At the beginning and at the end he must remember he could receive no credit for a single-handed achievement; but if he received no credit, neither could he receive discredit, for both are the portion of the Minister. The public health service had increased the expectation of life, but there was little use, he added, in making life longer unless we also made it better, and that too was the task of this service.

Irish Medical Schools and Graduates' Association

The annual dinner of this association will be held at the Savoy Hotel, Strand, London, W.C., on Thursday, Dec. 5th, at 7.45 P.M.

Ministry of Pensions Nursing Service

Miss Margaret L. Hunter, matron of the Ministry of Pensions Hospital, Dunston Hill, has been appointed principal matron of this service in the place of Miss Helen G. Palin, who retires next March.

Aldrich-Blake Travelling Scholarship

The trustees of the Aldrich-Blake memorial fund will award a scholarship in 1936 to a medical woman graduate for the purpose of travel and study either in this country or abroad. Further particulars will be found in our advertisement columns.

Diploma in Psychological Medicine

A course of lectures and practical instruction for the D.P.M. will be held at the Maudsley Hospital, Denmark-hill, London, S.E., from January to May. It is divided into two parts and part one will begin on Jan. 6th. Further particulars may be had from Dr. F. Golla, honorary director of the medical school at the hospital.

Pharmaceutical Society of Great Britain

A meeting of this society will be held at the house of the society (17, Bloomsbury-square, London, W.C.), on Tuesday, Dec. 10th at 8.30 P.M. Mr. Percival Hartley, D.Sc., director of the department of biological standards at the National Institute for Medical Research, will give a lecture on international biological standards for drugs and therapeutic substances.

Grove Hospital, Tooting

To-day Friday, at 3.30 P.M., Mr. W. R. Owen is opening the new isolation block erected by the London County Council at this hospital. It is a two-storey building and provides accommodation for 60 patients in single-bedded wards which are separated by partly glazed screens with duty rooms placed so that the nurses will be able to keep the patients under observation.

Studentship in Oto-laryngology

A Bernhard Baron research studentship will shortly be vacant at the Ferens Institute of oto-laryngology at the Middlesex Hospital. The student will be expected to devote his whole time to research in connexion with the nose, throat, or ear, under the general direction of the two senior surgeons to the department. The fellowship is open to registered medical men of pure British descent, and applications should reach the school secretary, Middlesex Hospital, London, W.1, not later than Dec. 6th.

Fellowship of Medicine and Post-Graduate Medical Association

Special classes for M.R.C.P. candidates will be given at the Brompton Hospital in chest diseases twice weekly at 5 P.M. from Dec. 9th to Jan. 10th, and at the Victoria Park Hospital in diseases of the heart and lungs on Wednesdays and Fridays at 6 P.M. from Dec. 10th to Jan. 10th. Full information may be obtained from the secretary of the fellowship at 1, Wimpole-street, London, W.1.

Society of Apothecaries of London

At recent examinations the following candidates were successful:—

Surgery.—F. E. Bedell, St. Mary's Hosp.
Medicine.—E. E. LeFeuvre, St. Mary's Hosp.; and M. A. Partridge, Univ. of Oxf. and Guy's Hosp.
Forensic Medicine.—M. A. Partridge, Univ. of Oxf. and Guy's Hosp.
Midwifery.—H. Firman, Univ. of Manch.; O. A. L. Goode, Univ. of Leeds; N. R. James, London Hosp.; F. R. Neubert, Univ. of Liverp.; C. J. Roberts, Westminster Hosp.; G. N. Rodgers, Bombay and West London Hosp.; J. W. Thomas, Welsh National School of Medicine; and P. Tobin, Middlesex Hosp.

The following candidates, having completed the final examination, have been granted the diploma of the society entitling them to practise medicine, surgery, and midwifery: H. Firman, E. E. LeFeuvre, and F. R. Neubert.

Public Health Plans for Leicester

The Leicester health committee are planning many extensions in their work during the coming year. The centralisation of all departments in a new civic health centre will cost about £200,000 and extensions to the isolation hospital, which will give it from 140 to 200 additional beds, at least another £100,000. A new nurses' home to accommodate 300 nurses is needed and at the general hospital a new department to deal with the aged and senile.

Measles Prophylaxis in London

In view of the anticipated epidemic of measles in the coming winter the appropriate committee of the London County Council submitted on Tuesday a proposal to extend the existing service of blood donors. The value of adult serum in the prevention and attenuation of attacks of measles is accepted by the committee. A payment of 5s. is to be offered for a blood donation and the total cost during the epidemic is estimated at £250 for payments to donors and £100 for apparatus, the total not exceeding £350. The council accepted the recommendation.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 16TH, 1933

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2779; diphtheria, 1243; enteric fever, 30; acute pneumonia (primary or influenzal),* 762; puerperal fever, 36; puerperal pyrexia, 102; cerebro-spinal fever, 12; acute poliomyelitis, 14; encephalitis lethargica, 6; dysentery, 26; ophthalmia neonatorum, 64. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Nov. 22nd was 3250, which included: Scarlet fever, 1175; diphtheria, 1263; measles, 74; whooping-cough, 20; enteric fever, 20 mothers (plus 10 babies); poliomyelitis, 8. At St. Margaret's (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 26 (0) from measles, 1 (0) from scarlet fever, 15 (1) from whooping-cough, 28 (4) from diphtheria, 32 (12) from diarrhoea and enteritis under two years, and 31 (4) from influenza. The figures in parentheses are those for London itself.

Manchester reported 13 deaths from measles, Liverpool 5, Bootle 4, no other great town more than 1. Manchester also reported 3 deaths from whooping-cough, Liverpool 2, no other great town more than 1. Deaths from diphtheria were reported from 17 great towns, Liverpool 4, Sheffield 3, Southampton, Bradford, and Manchester each 2. The mortality from influenza is scattered over 25 great towns, only Manchester, Stockport, and Birmingham reporting 2 deaths; no other great town more than 1.

The number of stillbirths notified during the week was 279 (corresponding to a rate of 45 per 1000 total births), including 44 in London.

* Although the definition of the notifiable forms of pneumonia has not been changed, the Weekly Return in its summary of notifications has replaced the heading Acute pneumonia (primary or influenzal) with the single word Pneumonia.

A SURVEY OF NUTRITION

At the September meeting of the Assembly of the League of Nations the problem of nutrition in its relation to public health was referred to a committee. Mr. Bruce, High Commissioner for Australia, who moved the resolution, stated the essentials of the problem in his description of the paradox of the glutted market for the farmer and the insufficient nourishment in the "protective foodstuffs" of a substantial proportion of mankind. In this committee there was a challenging discussion which lasted for three days and in which 20 delegations took part. Delegates pressed the need for greater knowledge of the facts if schemes of nutrition are to be established on a scale adequate to affect the problem, and Australia's demand for an inquiry met with unanimous approval.

The Expert Commission on Nutrition meeting this week in London is the result of this resolution. Delegates are present as follows:—

FRANCE

Prof. L. ALQUIER, director of the Institute of Alimentary Hygiene, Paris.
 Dr. L. LAPICQUE, professor of physiology at the Sorbonne, Paris.

SCANDINAVIA

Prof. AXEL HÖJER, general director of the Medicinalstyrelsen, Stockholm.

UNITED KINGDOM

Dr. E. P. CATHCART, F.R.S., professor of physiology, Glasgow University.
 Dr. E. MELLANBY, F.R.S., secretary of the Medical Research Council.
 Sir JOHN ORR, F.R.S., director of the Imperial Bureau of Animal Nutrition, Aberdeen.

UNITED STATES OF AMERICA

Dr. E. V. McCOLLUM, professor of biochemistry, Johns Hopkins University, Baltimore.
 Prof. MARY S. ROSE, Columbia University, New York.
 Dr. W. SEBRELL, National Institute of Hygiene, Washington.

U.S.S.R.

Prof. SBARSKY, director of the Central Nutrition Institute, Moscow.

They are meeting at the London School of Hygiene and Tropical Medicine with Prof. Mellanby as chairman and Prof. McCollum as vice-chairman, and after a preliminary exchange of views they decided to draft a statement on scientific principles governing the dietaries of certain groups—namely, women during pregnancy and lactation, infants, school-children, and adolescents up to the age of 21. Two subcommittees have been set apart, one on energy-producing substances, under the chairmanship of Prof. Cathcart, with Dr. H. E. Magee, Ministry of Health, as secretary; the other on non-energy-producing substances, such as vitamins and salts, under the chairmanship of Prof. McCollum, with Miss Harriette Chick, D.Sc., Lister Institute, as secretary. These subcommittees are drawing up detailed recommendations to be submitted to a plenary session of the expert committee.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—The Prince of Wales has appointed Sir Ernest Pooley to be an hon. secretary of this fund.

Medical Diary

Information to be included in this column should reach us proper form on Tuesday, and cannot appear if it reaches later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.1.
TUESDAY, Dec. 3rd.

Orthopaedics. 5.30 P.M. (Cases at 4.30 P.M.) Mr. H. F. M. Moseley: The Results of a Large Group of Cases Treated Operatively for Recurrent Dislocation of the Shoulder. Mr. St. J. D. Buxton: Cases illustrating the Result of Tavernier's Operation. Mr. Norman Capener: Two Cases Treated by Nicola's Method. Mr. C. Lambriudi: Arthrodesis of the Toes.

Pathology. 8.30 P.M. P. Fildes: Tetanus Spores in Wood Wool. E. Christine Pillman-Williams: Gastric Acidity in Pregnancy. W. G. Barnard: The Lining Cells of the Lung Alveoli. T. H. C. Benians: The Effect of Congo Red on Plasma and Leucocytes. I. H. Maclean and W. A. Fleming: The Incidence of Toxicogenic Staphylococci in Normal People. L. B. Holt: The Antitoxin Response to Varying Doses of Staphylococcus Toxoid. R. J. V. Pulvertaft: Bacterial Fluorescence with Ultra-violet Light. The Nature of Decolorisation in Chloroma.

WEDNESDAY.

History of Medicine. 5 P.M. Dr. H. P. Bayon: The Precursors of William Harvey. Dr. J. F. Halls Dally: The Story of the Circulation in Harvey's Time and After.

Surgery. 8.30 P.M. Specimens illustrating morbid conditions of the breast will be shown.

THURSDAY.

Tropical Diseases and Parasitology. 8.15 P.M. Prof. D. Keilin: Hemoglobin and its Derivatives.

FRIDAY.

Otology. 10.30 A.M. (Cases at 9.30 A.M.) Mr. D. F. Duxward: The Facial Nerve and its Connections. Mr. E. H. Richards: Unexpected Sequelae to Aural Operations.

Laryngology. 5 P.M. (Cases at 4 P.M.) Discussion. Mr. F. Holt Diggle and Mr. T. E. Cawthorne: Treatment of Acute Frontal Sinusitis.

Anesthetics. 8.30 P.M. Dr. Stanley Rowbotham: Cyclopropane. (Dr. Rowbotham will demonstrate the use of Cyclopropane at the Cancer Hospital, Fulham-road, S.W., at 5 P.M.)

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, Dec. 6th.—8.30 P.M. (De Vere Hotel, Kensington), Sir Bernard Spilsbury, Dr. Edwin Smith, Sir William Wilcoxon, and Judge Higgins: The Medical Witness.

SOCIETY OF CHEMICAL INDUSTRY.

London Section.

MONDAY, Dec. 2nd.—8 P.M. (Burlington House, Piccadilly, W.), Mr. J. Gibson: Industrial Disinfectants.

SOCIETY OF PUBLIC ANALYSTS.

WEDNESDAY, Dec. 4th.—8 P.M. (Chemical Society's Rooms, Burlington House, Piccadilly, W.), Short Communications.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

UNIVERSITY OF LONDON.

MONDAY, Dec. 2nd, WEDNESDAY, and THURSDAY.—5.30 P.M. (London School of Hygiene and Tropical Medicine, Keppel-street, W.C.), Major-General Sir John Megaw: Neglected Aspects of Public Health Work, with special reference to India.

FRIDAY.—5.30 P.M., Prof. F. W. Twort, F.R.S.: Modern Views of the Bacteriolytic Agents and their relation to Viruses.

CHADWICK PUBLIC LECTURE.

TUESDAY, Dec. 3rd.—8.15 P.M. (The Inner Temple Hall, E.C.), Mr. R. C. Maxwell: Town Planning and the Housing Act.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.1.

MONDAY, Dec. 2nd, to SATURDAY, Dec. 7th.—BROMPTON HOSPITAL, S.W.3. All-day course in thoracic surgery.—LONDON LOCK HOSPITAL, 91, Dean-street, W. Afternoon course in venereal disease.—INFANTS HOSPITAL, Vincent-square, S.W. Afternoon course in diseases of infants.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars, S.E. Afternoon course in dermatology.—Courses are open only to members of the fellowship.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.

WEDNESDAY, Dec. 4th.—3 P.M. Visit to the Radiotherapeutic Department, Lambeth Hospital, Brook-street, S.E.11, with Dr. G. F. Stebbing.

KING'S COLLEGE HOSPITAL, Denmark Hill, S.E.

THURSDAY, Dec. 5th.—9 P.M., Mr. E. G. Muir: Visceral Tuberculosis.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, N.W.

WEDNESDAY, Dec. 4th.—Dr. A. Abrahams: Insomnia and other Disturbances of Sleep.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Dec. 2nd.—3.30 P.M., Dr. Greenfield: The Chemistry of the Cerebro-spinal Fluid (II.).

TUESDAY.—3.30 P.M., Dr. Critchley: Epilepsy and Allied Conditions.

WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.

THURSDAY.—3.30 P.M., Dr. Walshe: The Motor System (IV.).

FRIDAY.—3.30 P.M., Dr. Gordon Holmes: Disorders of Vision (III.).

Out-patient clinic daily at 2 P.M.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Dec. 5th.—2 P.M., Dr. B. E. Schlesinger: Exanthemata. 3 P.M., Dr. D. N. Syphilis (II.).

at 10 A.M. and ward visits (except P.M.)

ROYAL INFIRMARY, Manchester.

TUESDAY, Dec. 3rd.—4.15 P.M., Dr. Crighton Bramwell: Diagnosis and Treatment of Cardiac Pain.

FRIDAY.—4.15 P.M., Mr. P. R. Wrigley: Demonstration of Surgical Cases.

ANCOATS HOSPITAL, Manchester.

THURSDAY, Dec. 5th.—4.15 P.M., Clinical Meeting.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE EAR, NOSE, THROAT, AND CHEST, Deansgate, Manchester.

WEDNESDAY, Dec. 4th.—4.30 P.M., Dr. Simon Kelly: Affections of the Pleura.

ST. MARY'S HOSPITALS, Manchester.

THURSDAY, Dec. 5th.—4.15 P.M. (Whitworth-street West Hospital), Dr. Newton: Forceps.

GENERAL INFIRMARY, Leeds.

TUESDAY, Dec. 3rd.—3.30 P.M., Mr. W. Gough: Prolapse.

PUBLIC DISPENSARY AND HOSPITAL, Leeds.

WEDNESDAY, Dec. 4th.—4 P.M., Dr. S. J. Hartfall: Difficulties arising in the Treatment of Anæmia.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, Dec. 4th.—4.15 P.M. (Victoria Infirmary), Dr. O. H. Mavor: Chronic Respiratory Disease.

Births, Marriages, and Deaths

BIRTHS

CAMPBELL.—On Nov. 9th, at a Rugby nursing-home, the wife of George Campbell, M.B. Oxon., of Wolston, Coventry, of a daughter.

HARE.—On Nov. 13th, at St. Albans, the wife of Tom Hare, M.D. Liverp., of a daughter.

HAYTHORNTHWAITHE.—On Nov. 22nd, at the West Herts Hospital, Hemel Hempstead, the wife of Captain R. A. Haythornthwaite, I.M.S., of King's Langley, Herts, of a son.

KAPP.—On Nov. 17th, at Croydon, to Dr. Dorothy Kapp (née Wilkins), wife of Prof. Reginald Kapp—a son.

PHILPS.—On Nov. 20th, at Beccles, the wife of Alan Philps, F.R.C.S. Eng., of a daughter.

SCOTT.—On Nov. 12th, at Ringwood, Hants, the wife of J. A. Easton Scott, B.M. Oxon., of a daughter.

RAWDON SMITH.—On Nov. 18th, at Liverpool, the wife of G. F. Rawdon Smith, M.D. Liverp., of a son.

WAKELEY.—On Nov. 23rd, the wife of Cecil P. G. Wakeley, D.Sc. Lond., F.R.C.S. Eng., of Queen Anne-street, W.1, of a son.

MARRIAGES

KENNERLEY-REYNOLDS.—On Nov. 16th, at St. Peter's Church, Harborne, Dr. T. A. S. Kennerley to Eleanor Judith, second daughter of Mr. and Mrs. J. H. Reynolds, of Harborne, Birmingham.

MANSELL-NEWBY-BARNES.—On Nov. 23rd, at St. Augustine's Church, Queen's Gate, S.W.7, Harry Edward Mansell, B.M. Oxon., M.R.C.P. Lond., eldest son of Dr. and Mrs. H. R. Mansell, of Hastings, to Jean, elder daughter of Mr. and Mrs. Robert Newby-Barnes, of South Milford, Yorkshire.

DEATHS

LELAND.—On Nov. 23rd, at Sloane-street, Alfred Burnet Leland, M.B., C.M. Edin.

MAIR.—On Nov. 22nd, at Matheson-road, W., Lieut.-Colonel Edward Mair, I.M.S. (retired).

NALL.—On Nov. 11th, suddenly, John Frederick Nall, M.D. Durh., F.R.C.S. Eng., at Torquay, late of Rahere, Clayfield, Brisbane, aged 72.

NASH-WORTHAM.—On Nov. 24th, at Bournemouth, Francis Leslie Dalton Nash-Wortham, F.R.C.S. Edin., late of Dorchester, aged 54.

STEWART.—On Nov. 22nd, at River-street, Johannesburg, William Stewart, M.R.C.S. Eng., M.I.E.E., aged 59.

WILCOX.—On Nov. 20th, at Salisbury, Robert Lewis Wilcox M.R.C.S. Eng., L.S.A., who practised 44 years in Westminster, aged 89 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

INFIBULATION

By JOHN M. MELLY, M.C., B.M., F.R.C.S. Edin.
PRINCIPAL MEDICAL OFFICER, BRITISH AMBULANCE
SERVICE IN ETHIOPIA

A CURIOUS surgical practice, which is almost universal among the natives of Somaliland, is that of female circumcision, or infibulation. To what era this custom dates back it is impossible to say; certainly the natives themselves have no light to throw on the origin of the practice. It has been handed down from time immemorial, and no female child is exempt. Although the custom is also found in Ethiopia, in parts to which the Somalis have penetrated, it is there often considerably modified in form. As performed in Somaliland proper, however, it is still an extensive surgical procedure.

The operation is not done in early infancy, as might be supposed, but when the child has reached her seventh year. The only reason I could elicit for this particular age choice is that up to seven years old the young girl may be considered fairly safe from male interference. Thus it would appear that the operation is postponed to as late a date as is socially advisable, with a view to the patient being capable of withstanding the shock and after-effects of the operation itself. This is probably the result of generations of experience, and justifies itself in the repeated denials of the native women that there is ever any resulting mortality—whether from hæmorrhage, sepsis, or any other cause.

The result aimed at, and usually more or less completely achieved, is the removal of the labia minora and the glans and body of the clitoris, and the subsequent closure by suture of the whole vulva with the exception of about 1 cm. posteriorly, opposite the vagina. The object is declared to be the insurance of virginity until marriage, when a second operation is performed to open up the orifice of the vagina sufficiently for marital purposes. Whether the removal of the nymphæ and clitoris is intended further to reduce the risk of premarital intercourse by diminishing sensation, or whether these amputations are employed with the sole object of obtaining raw surfaces for suture and closure, remains a matter for conjecture. Native opinion takes the attitude that this is the customary procedure, and it has apparently been unquestioningly adopted from one generation to another. It seems likely, however, that the details of the whole operation were in the beginning deliberately planned to ensure virginity both by lessening desire and by creating a definite physical obstruction to its fulfilment. The originators may have had an even longer vision and in incorporating the amputations perhaps had in view the discouragement of unfaithfulness in the future wives of the race—a sort of Somali chastity-belt. The efficacy of the operation in this respect there was no available means of gauging. Somalis are as reticent as more civilised peoples in admitting the indiscretions of their own wives, and probably correspondingly unreliable in claiming conquests over those of their neighbours.

Although I have never seen the operation performed, I was able to obtain a fairly detailed account of the procedure, and to examine a number of healed cases. There are one or more older women in each tribe who are skilled in the technique, and to these women the girls are taken when they are seven years old. The operation fee among the more civilised tribes is 2 rupees (about 3s.) but among the remoter tribes it is probably considerably less, and may there be paid in cattle, sheep, &c. A herb, or a concoction of herbs, which I was unable to identify, is applied to the parts before operation, and is declared to have a marked analgesic effect. As it is the women

themselves who affirm this, there is probably some truth in what they say. A somewhat crude knife is used and two curved incisions are made from the clitoris to the fourchette, completely severing the labia minora. The clitoris itself is then removed at the point where the body joins the crura. Finally the raw edges are sutured together with gut obtained from the intestine of the sheep and prepared by the natives themselves. Apparently hæmorrhage is adequately controlled by paste prepared from local herbs, again unidentified, which is thickly applied to the whole wound when the operation has been completed. A wood fire, which has been burning close at hand, is then raked away, and the patient placed for a few minutes in a sitting position on the hot ground. After-treatment is simple but based on sound principles. The legs are bound firmly together above and below the knees and at the ankles, and the child is kept in bed on a diet of camel's milk. After three days she is allowed to get up and move about as much as she is able. Since her legs are still tied together, this is accomplished with the aid of a pole which the patient holds in front of her with both hands, progressing in small jumps. After seven days the wound is considered to be healed and the legs are released.

That sepsis should supervene would, on the face of it, seem to be inevitable. The whole wound must be periodically infiltrated with urine, and when it is remembered that amongst the Somalis a smooth stone takes the place of toilet paper after defæcation, infection from that source, too, would appear probable. However, I was able to elicit no admission of this complication, and examination of the resultant wound in every case suggested healing by first intention.

The appearance of the healed wound shows the labia majora meeting in the midline in a clean scar about $\frac{1}{2}$ inch wide. The scar extends from the amputated clitoris anteriorly to within 1 cm. of the fourchette, where there is a circular opening into the vagina admitting the tip of the little finger. The whole effect produced was that of a clean operation skillfully performed under aseptic conditions.

The second operation is undertaken immediately before marriage, and in Somaliland is also performed by a woman of the tribe, though in Ethiopia, in the parts where infibulation is practised, the husband may prefer to do it himself. It consists in a simple incision, to whatever depth is considered adequate, along the full length of the old scar. The question of preoperative shaving of the operation area does not arise, as Somali women tolerate no pubic hair, and, while keeping their eyebrows intact, assiduously pluck the pubic growth.

The result of this second operation, in addition to widening the vaginal orifice, is to restore with unexpected completeness the normal external appearance of the vulva. The cleft between the labia majora reappears, though on parting the labia, the vestibule is found to be completely replaced by scar tissue.

Apparently it is not infrequently necessary to repeat the operation of infibulation on the same patient one or more times; not, it is averred, owing to failure of technique on the part of the operator, but owing to the natural weakness of the flesh of the patient concerned.

THE PARLIAMENTARY MEDICAL COMMITTEE.—In a note last week on Medical Men in Parliament reference was made to the fact that all the Members of Parliament who are medically qualified meet from time to time on a non-party basis to consider matters of special interest to public health and the practice of medicine. Of this Parliamentary Medical Committee Sir Francis Fremantle has for many years been the chairman and Dr. A. B. Howitt the secretary.

ADMINISTRATION OF THE CONVENTIONS ON TRAFFIC IN DANGEROUS DRUGS

In a report by the advisory committee on traffic in opium and other dangerous drugs recently presented to the League of Nations an interesting account is given of the method of working of the import and export certificate system whereby the international traffic in dangerous narcotics is controlled. The Hague Opium Convention of 1912, by articles 3, 5, and 13, contemplated the setting up of a system of "import certificate and export authorisation" and the advisory committee, with the approval of the Council and Assembly of the League adopted in 1921 the method in vogue in Great Britain during the late war. By the Geneva Convention of 1925 a legal obligation was imposed on an importing country to return the export authorisation to the government of the exporting country specifying the actual amounts of the narcotics which had been imported. By the same convention the coca leaf and Indian hemp were added to opium, its derivatives and cocaine to be subjected to the same traffic control. By the Limitation of Manufacture Convention of 1931 countries party to it, even if not parties to the previous conventions, are brought within the requirements of the import certificate system in respect of all drugs specified in Group I. of that convention as well as of those in Group II., except such as are in normal therapeutic use. By means of a model administrative code, supplemented by an explanatory graph, and a system of registration this rather complicated arrangement can be readily understood and effectively applied by any government which is willing, and indeed bound, to secure the limitation of the production and distribution of dangerous narcotics to legitimate and scientific purposes. The report concludes with a list of 72 countries indicating the conventions to which each country is party and the name and address of the authority in each country which is responsible for issuing import certificates and export authorisations.

CONTENT IN RETIREMENT

THE idea of retirement conjures up for one doctor a blissful vision, for another a horrid spectre, for a third grey monotony in contrast to the varied colours of a busy life. Even those who feel certain of their capacity, natural or acquired, to enjoy leisure are liable to become uneasy when they encounter the false heartiness characteristic of five-day members of the less expensive golf clubs. As a corrective to a gloomy outlook on retirement, we recommend Dr. Philip Gosse's account¹ of his happy country life with a collection of books, largely about pirates; pets, all cold-blooded; and such diversions as mushroom hunting and the promotion of the S.S.S.S. (Society for the Spread of Sticklebats in Sussex). Anecdotes are not wanting of the warm-blooded pets of the past: Gupworthy the badger, Miss Nosey Parker, a ringtail coatimundi, George, an Australian flying phalanger, and Greta the shrietch. But the pain of losing them proved more intense and lasting than the pleasures of friendship during their brief lives; and their successors are reptiles and fish, for, as Dr. Gosse truly says, you can never become deeply attached to a fish. All will enjoy this book, though some may pause to wonder whether its versatile author is really a fair sample of a doctor in retirement—whether, in fact, the notes are not those of a countryman whose excursions into medical study and practice were just episodes in a life conducted in a spirit of joyous adventure.

NEW PREPARATIONS

"HYPOLOID" HISTIDINE HYDROCHLORIDE, a product of Burroughs Wellcome and Co., Snow Hill Buildings, London, E.C.1, provides a sterile 4 per cent. solution of histidine hydrochloride suitable for

immediate use in cases of gastric or duodenal ulcer. This treatment is based on results obtained in 1933 by Aron and Weiss, who found that histidine and tryptophane prevented the formation of gastric ulcers in dogs whose duodenal digestion was surgically abolished. They suggested that peptic ulcers may be caused by amino-acid deficiency, and in our own columns a year ago E. Bulmer was able to confirm their observation that in human beings histidine injections are often followed by symptomatic cure of ulcer with removal of radiographic abnormalities. Subsequent writers have emphasised the harmlessness of the remedy, and the fact that, in mild cases at any rate, it can be given without special dieting or confining the patient to bed. The course recommended by Messrs. Burroughs Wellcome consists of 5 c.cm. of their preparation, by intramuscular or subcutaneous injection, daily for three weeks. "No other medication is necessary, and a minimum, if any, of dietary restrictions." Ampoules of 5 c.cm. are supplied in boxes of five.

COSOME (EPHETONIN COUGH SYRUP).—Ephetonin is a synthetic ephedrine prepared by E. Merck, of Darmstadt (London address: 37, Golden-square, W.1), and this firm has now put on the market a cough syrup in which it is associated with Dionin (ethyl-morphine hydrochloride) in the following mixture: ephetonin, 0.2 g.; dionin, 0.04 g.; syrup thymi comp., ad 100 c.cm. The last-named syrup has previously been recommended and used for some years in the treatment of cough, and its action, Messrs. Merck believe, is improved by the addition of ephetonin, to dilate bronchioles and promote expectoration, and of dionin to alleviate irritation and pain. Cosome is intended for the relief of all kinds of cough—especially whooping-cough—and its use is suggested as a preventive of post-operative pulmonary infections. The manufacturers claim that it never gives rise to side-symptoms or habituation.

PETROLAGAR WITH CASCARA.—Petrolagar is an emulsion of liquid paraffin with agar and is used as a laxative. The Petrolagar Laboratories (Braydon-road, London, N.16) have hitherto sold three varieties: (1) plain, (2) with phenolphthalein, and (3) alkaline. To these they now add a fourth petrolagar with cascara. It is described as combining "the mechanical softening action of petrolagar with the stimulating action of fluid extract of cascara sagrada," and each fluid ounce contains the equivalent of 61 minims of this extract. The exact composition, which includes (by weight) 62 per cent. of liquid paraffin and 14.7 per cent. of fluid extract of cascara, is stated on each bottle. The manufacturers have been successful in making a preparation which is pleasant to take. They suggest that it should be particularly useful for the relief of constipation in pregnancy.

PAR-ISALON.—This is a new remedy for bronchial asthma made by Dr. Joachim Wiernik A.-G. Berlin-Waidmannslust, and sold by Messrs. Coates and Cooper Ltd., 94, Clerkenwell-road, London, E.C.1. Isalon "Divag" is described as a substance belonging to the adrenaline series, and is said to have a bronchodilator action without any of the side-effects ascribed to adrenaline and ephedrine. In Par-Isalon it is mixed with theobromine, caffeine, and phenazone, with the idea of lessening other symptoms often associated with chronic asthma. It is taken by mouth. Favourable reports are quoted from Germany.

A LIFE OF EMIL AND KATE BEHNKE

Miss K. E. Behnke, 39, Earl's Court-square, London, S.W., writes: "I am writing a Life of my parents, Emil and Kate Behnke, whose research into vocal physiology and subsequent work in the scientific training of the voice, and the treatment of defects of speech, met with such cordial appreciation from, and close coöperation with, members of

¹ Go to the Country. By Philip Gosse. London: Cassell and Co., Ltd. 1935. Pp. 282. 8s. 6d.

the medical profession, amongst whom they counted so many warm friends. If any of these should have in their possession letters or information which they would allow me to incorporate in the biography I should be grateful for the loan of them. Every care would be taken of them and they would be returned in due course to the owners."

Appointments

COATES, J. F., M.D., M.R.C.P. Lond., has been appointed Senior Resident Medical Officer at the Victoria Hospital for Children, Chelsea.

ELLIS, RICHARD W. B., M.D. Camb., M.R.C.P. Lond., Assistant Physician to the Queen's Hospital for Children, Hackney

HERITAGE, KENNETH, M.S. Lond., F.R.C.S. Eng., Hon. Assistant Surgeon to the Princess Beatrice Hospital, London.

JAMES, S. G., Ch.M. Sydney, M.R.C.P. Lond., D.P.M., Deputy Medical Superintendent of the Rampton State Institution for Mental Defectives.

JONES, T. BRAMWELL, M.B. Camb., Resident Medical Officer to the Heritage Orthopaedic Hospitals, Chorley.

LANCKENAU, NELLIE I., M.D. Lond., Hon. Physician to the Department of Physical Medicine of the Prince of Wales's General Hospital, London.

MACKIE, E. GORDON, M.B. St. And., D.O.M.S., Hon. Ophthalmic Surgeon to the Sheffield Royal Hospital.

PARSONS, C. G., M.B., Resident Medical Officer and Medical Registrar at the General Hospital, Birmingham.

WHITWELL, G. P. B., M.D. Lond., Medical Officer at the Rampton State Institution for Mental Defectives.

Certifying Surgeons under the Factory and Workshop Acts:—
Dr. C. G. SHEROWIT (Stapleford District, Nottingham);
Dr. A. BURLINGHAM (Leiston District, Suffolk); Dr. R. A. CUMMING (Aberchirder District, Banff); Dr. F. ARMSTRONG (Rhondda (Treorchy) District of Glamorgan).

Vacancies

For further information refer to the advertisement columns

Aberdeen Royal Mental Hospital.—Sen. Asst. Physician.

Aldrich-Blake Memorial Trust, 8, Hunter-street, W.C.—Travelling Scholarship. 200 guineas.

Barnsley, Beckett Hospital and Dispensary.—H.P. £200.

Barry, Accident and Surgical Hospital.—H.S. At rate of £200.

Battersea General Hospital, Battersea Park, S.W.—H.S. Also H.P. At rate of £130 and £120 respectively.

Belfast, Royal Maternity Hospital.—Res. M.O. At rate of £52.

Bournemouth, Royal National Sanatorium for Consumption, &c. Asst. Res. M.O. £200.

Bradford, Royal Eye and Ear Hospital.—H.S. £160.

Brighton, Sanatorium and Infectious Disease Hospital.—Jun. Res. M.O. At rate of £250.

Brighton, Sussex Eye Hospital, Eastern-road.—H.S. At rate of £150.

Cardiff Royal Infirmary.—Gynaecological H.S. At rate of £50.

Colchester, Essex County Hospital.—Hon. Ophth. Surgeon.

Covenbury and Warwickshire Hospital.—Res. H.S. £125.

Dublin University.—Professorship of Physiology.

East Ham Memorial Hospital, Shrewsbury-road, E.—H.S. to Special Depts. and Cas. O. At rate of £120.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—H.P., three H.S.'s, Obstet. Asst. Each £50. Also Hon. Clin. Assts. to Med. and Surg. Out-patient Dept. and Skin Dept.

Exelina Hospital for Sick Children, Southwark, S.E.—H.S. £120.

Exminster, Devon Mental Hospital.—Jun. Asst. M.O. and Pathologist. £350.

Gloucestershire Royal Infirmary.—H.S. At rate of £150.

Hamstead General and N.W. London Hospital, Haverstock Hill, N.W.—H.S. At rate of £100.

Hastings, Royal East Sussex Hospital.—Jun. H.S. At rate of £150.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Surg. Reg. £100.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. H.P. Also Res. H.S. Each at rate of £100.

Hospital for Tropical Diseases, Gordon-street, W.C.—H.P. At rate of £120.

Hull Municipal Maternity Home and Infants Hospital.—Jun. Res. M.O. At rate of £100.

Ilford, King George Hospital.—Two H.P.'s. Also three H.S.'s. Each at rate of £100.

Inverness Royal Northern Infirmary.—Bacteriologist and Pathologist. £800.

King's College Hospital, Denmark Hill, S.E.—Asst. Hon. Anaesthetist.

Leeds Education Committee.—Asst. School M.O. £500.

Liverpool, Mill-road Infirmary.—Res. Asst. M.O. £200.

Liverpool, Walton Hospital.—Sen. Res. Asst. M.O. £350.

London Hospital, E.—Surg. first Assistant and Reg. £300. Also Hon. Asst. Anaesthetist.

London Lock Hospital, 233, Harrow-road, W.—Res. M.O. for Male Depts. At rate of £175. Also Surg. Reg. to Dean-street. £100.

Manchester, Ancoats Hospital.—Asst. Pathologist. £300.

Manchester Royal Infirmary.—Res. M.O. £200.

Manchester, St. Mary's Hospital.—H.S.'s for Special Hospitals. Each at rate of £50.

Marie Curie Hospital, 2, Fitzjohn's avenue, N.W.—Res. M.O. At rate of £100.

Maudsley Hospital, Denmark Hill, S.E.—Asst. M.O. £170.

Miller General Hospital, Greenwich-road, S.E.—Refractionist. 52 guineas.

Ministry of Health.—M.O.'s. Each £847.

Mitcham, Wilson Hospital.—Hon. Consulting Gynaecologist.

National Hospital for Diseases of the Nervous System, Queen-square, W.C.—Two H.P.'s. Each £150. Also Visiting M.O. for Convalescent Home.

National Temperance Hospital, Hampstead-road, N.W.—Cas. O. At rate of £120.

Newcastle General Hospital.—Two H.S.'s. Each at rate of £150.

Newcastle-upon-Tyne City and County.—Asst. Maternity and Child Welfare M.O. £500.

Nottingham City.—Asst. M.O. for Maternity and Child Welfare Work. £500.

Nottingham General Hospital.—H.P. and H.S. Each at rate of £150.

Oxford, Christ Church Hospital.—H.S. £100.

Preston, County Mental Hospital, Whittingham.—Res. Jun. Asst. M.O. £500.

Princess Elizabeth of York Hospital for Children, Shadwell, E.—H.S. Also Cas. O. Each at rate of £125.

Queen's Hospital for Children, Hackney-road, E.—H.P. and Cas. O. Each at rate of £100. Also Dental Surgeon. £1 7s. 3d. per session.

Radium Institute, Riding House-street, W.—H.S. At rate of £150.

Rainhill, Lancs, County Mental Hospital.—Asst. M.O. £500.

Reading, Royal Berkshire Hospital.—H.S. At rate of £125.

Romford, Oldchurch Hospital.—Asst. Res. Surgeon. £500.

Royal Free Hospital, Gray's Inn-road, W.C.—Second H.S., Surg. Reg. £200. Res. Cas. O. At rate of £150. Dist. Obstet. Asst., Gynaecological Reg.; also Med. Reg. Each at rate of £100, and Res. Anaesthetist in Obstet. and Gyn. Unit at rate of £75.

Royal Northern Hospital, Holloway, N.—Hon. Radiologist.

St. Albans, Hill End Hospital, for Mental and Nervous Disorders. Fourth Asst. M.O. £350.

St. Bartholomew's Hospital, E.C.—Chief Asst. to X Ray Diagnostic Dept.

St. John's Hospital, Lewisham, S.E.—Res. Cas. O. At rate of £100.

St. Mark's Hospital for Cancer, &c., City-road, E.C.—Res. Surg. O. At rate of £150. Also Clinical Assistantships for Out-patients' Depts.

St. Mary's Hospital for Women and Children, E.—Hon. Anaesthetist.

St. Peter's Hospital for Stone, &c., Henrietta-street, W.C.—Clin. Asst.

Salford Royal Hospital.—H.S. At rate of £125.

Salisbury General Infirmary.—H.P. At rate of £125.

Sheffield Royal Infirmary.—Clin. Asst. to Surgical Dept. At rate of £300.

Southampton Borough General Hospital.—Jun. Res. M.O. £200.

Staffordshire General Infirmary.—H.S. At rate of £200. Also H.P. and Cas. O. At rate of £150.

Surrey County Mental Hospital Service.—Three Asst. M.O.'s. Each £350.

Warwickshire County Council.—Asst. County M.O.H. £500.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Jun. Res. H.S. £100.

West Bromwich, Hallam Hospital.—Res. H.P. At rate of £200.

West London Hospital, Hammersmith-road, W.—Med. Reg. £250. Also H.P. and two H.S.'s. Each at rate of £100.

Westminster Hospital, Broad Sanctuary, S.W.—Clin. Asst. to Gynaecological Dept.

Weston-super-Mare General Hospital.—Res. H.S. £150.

Windsor, King Edward VII Hospital.—Three H.S.'s. Each at rate of £100.

Wolverhampton, New Cross Hospital and Institution.—Asst. Deputy M.O. £350.

Wolverhampton Royal Hospital.—H.S. At rate of £100.

Medical Referee under the Workmen's Compensation Act, 1925, for the Brentwood, Chelmsford, Colchester, Clacton and Halstead, Harwich and Maldon County Court District (Circuit No. 33). Applications should be addressed to the Private Secretary, Home Office, Whitehall, London, S.W.1. before Dec. 10th.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Westboughton (Lancashire); Lynton (Devon); Kirkintilloch (Dumbarton); and Bradford (Cleckheaton) (York, West Riding).

THE Berliner Akademie für aerztliche Fortbildung, Berlin, has asked us to announce a correction in their programme which we published last week. The course in radiology will be held from March 9th to 14th and not as stated.

ADDRESSES AND ORIGINAL ARTICLES

SURGICAL TREATMENT OF ANEURYSMS

By W. H. C. ROMANIS, M.B., M.Chir. Camb.,
F.R.C.S. Eng.

Surgeon to St. Thomas's Hospital and to the City of
London Hospital for Diseases of the Chest

My interest in the treatment of "surgical" aneurysms dates from a series of 35 cases of traumatic arterial and arteriovenous aneurysms with which I dealt in the few years immediately after the war, and in connexion with which I had the advantage of the advice and assistance of the late Sir George Makins. The cases described now are however a different series and are of wider general interest because they are all civilian cases and not war injuries.

The aneurysms essentially suitable for surgery are naturally those of the neck and limbs, and as a rough general rule it may be laid down that the nearer the trunk the aneurysm is, the more difficult and delicate is its operative treatment. The cases here described have all been treated by open surgical operation, though of course it is well known that certain aneurysms can be benefited by such other procedures as compression, needling, electrolysis, and general medical measures. A bewildering variety of operations have been practised for aneurysm in the past; such procedures as ligation of the main vessel just above, or some distance above the sac, distal ligation of the main vessel or of certain branches, ligation above and below the sac, and direct excision of the sac, having all been extensively practised, while Matas' suturing operations have occasionally been done. Some of the operations are invested with the historical romance of long antiquity, such as the operation of Antyllus. Nowadays there is little doubt that, if it can be performed, the formal operation of excision of the sac with ligation of all branches entering it, as close to the sac as possible, and non-interference with the accompanying vein, is the operation of choice. Often it is impossible, either because of the situation of the aneurysm, its size, its adherence, or the patient's age or weakness, but in many such cases a cure is obtainable by one of the other surgical procedures, the most promising being ligation of the main vessel immediately above the sac.

As is well known, most of these so-called peripheral aneurysms occur in the flexures of the limbs, either in the popliteal space, Scarpa's triangle, or the axilla. Many, but by no means all of them, are associated with injuries. They are far more common in men than in women, but when seen in women they are usually associated with a positive Wassermann reaction, whereas this is by no means always the case in men. Certain aneurysms of this kind are, or have in the past been, associated with certain trades, such as the popliteal aneurysm seen in post-boys, and femoral aneurysm seen in butchers as a result of stabs in the thigh from their knives while sharpening them. Others are seen as a direct or indirect result of surgical procedures; the best known instance of this was the brachial aneurysm in the antecubital fossa which so often occurred as a result of unskilled attempts at bleeding. In the present series there are two instances where the aneurysms can apparently be traced directly or indirectly to surgical operations.

ARTERIOVENOUS ANEURYSMS OF THE CAVERNOUS SINUS

These aneurysms to which I shall first refer are not extremely rare. They are usually the result of severe

injury to the base of the skull; quite commonly the cause is a kick by a horse on the jaw, as a result of which a crack runs across the region of the cavernous sinus and a communication is formed between the internal carotid artery and this sinus. Clinically the condition is unmistakable: the patient complains of a continuous loud, roaring noise in his ears, pulsating exophthalmos is present, the eyelids are engorged, purple, and congested with prominent veins, while oedema of the conjunctiva is often present. The characteristic "machinery" murmur, which consists of a loud, continuous roaring or buzzing, increased at every heart beat, can sometimes be heard without a stethoscope, while with a stethoscope it is exceedingly loud, all over the frontal region. It is usually heard loudest over the frontal sinus and eyelid on the side concerned. It may not be easy to settle on which side the aneurysm is until it is noticed that the murmur is stopped more or less completely by compressing the common carotid artery on the affected side, and it is usually made worse by compression on the other side.

Treatment of this condition consists in ligation of the internal carotid artery on the affected side; ligation of the common carotid alone is not sufficient, as the blood will continue to come down the external carotid and go up the internal carotid. Ligation either of both the common and external carotid, or of the internal carotid alone, must therefore be performed. The latter procedure is the best.

The following are 3 out of 5 cases which have been dealt with:—

CASE 1.—Male, aged 33. Had been knocked down by a lorry and sustained a fractured base five years before. Pulsating exophthalmos and ulceration of the cornea were marked, while the roaring noise made life intolerable. The noise disappeared on compressing the right common carotid artery, and was made worse by compressing the left artery. Ligation of the right internal carotid artery was performed five years ago, and the noise has completely disappeared. No evil effects followed.

CASE 2.—Male, aged 21. Had been kicked on the jaw by a horse three years before. The usual signs and symptoms of this condition had followed, and a ligation of the common carotid artery was performed elsewhere a year afterwards. The patient stated that the noises disappeared in about a week, and then came back again almost as badly as ever. Pulsating exophthalmos was not very obvious; ligation of the internal carotid stopped these noises altogether.

CASE 3.—Male, aged 35. Had been kicked on the side of the face by a horse six months before. All the ordinary signs and symptoms were present and the noise could be heard without a stethoscope. Ligation of the internal carotid artery was performed four years ago and the noise has been very greatly diminished, although the patient says it has not quite disappeared.

ANEURYSMS OF THE CAROTID ARTERIES

Idiopathic aneurysms of the common carotid artery are occasionally seen in women, and a large number of them are bilateral. Sometimes they appear to increase in size up to a certain point and then remain more or less stationary. The condition is serious and dangerous if nothing is done for it and causes great discomfort. The following are three interesting instances, the first of which was apparently the direct result of a tonsillectomy probably from bruising or partial damage to the wall of the vessel.

CASE 4.—A girl, aged 12, was seen nine years ago with what was supposed to be a gland in the neck. She had had her tonsils and adenoids removed six months before. On examination the swelling was clearly an aneurysm in the neighbourhood of the bifurcation of

the carotid on the left side. It was the size of a large egg and had apparently increased rapidly in size. The Wassermann was negative. An incision was made and the aneurysm was explored. A large sac was found behind the vessel at the bifurcation, more or less wrapped round the common, external, and internal carotid arteries. It was necessary to tie all three vessels before pulsation ceased, while the sac extended too near to the base of the skull for excision to be possible. The child made an uninterrupted recovery though a small, firm, non-pulsating swelling has persisted ever since. This indeed nearly always happens unless the sac of an aneurysm is dissected out.

CASE 5.—Mrs. A., aged 54, was sent to see me with a diagnosis of a large goitre. When she entered the consulting-room a large symmetrical, bilobed swelling could be seen in the neck, looking indeed very much like a huge parenchymatous goitre. On examination it was quite obvious that the swelling consisted of two large symmetrical aneurysms of the common carotid arteries, each the size of a small coconut. The Wassermann reaction was negative and no cause for the condition could be assigned. Ligation of both common carotid arteries was performed with an interval of four months between the operations. No untoward symptoms occurred and all pulsation in the aneurysms has disappeared. The patient is perfectly fit but still has two hard non-pulsating swellings the size of hen's eggs. Recently she has asked me to remove these, but her state is so satisfactory that I am inclined to leave well alone.

CASE 6.—Mrs. B., aged 52, had a positive Wassermann reaction, and a big aneurysm of the left common carotid artery about the size of a very large hen's egg. Here it was possible to ligature the artery above and below the sac and dissect the sac out. This produced a complete cure.

It is noteworthy that in all the above cases ligation of one, or even both, common carotid arteries produced no hemiplegia or other untoward symptoms, but the liability to this and also to gangrene of a limb after ligation of a main vessel is of course much diminished when an aneurysm has been there for some time previously.

INNOMINATE ANEURYSM

CASE 7.—Mrs. C., aged 52, complained of pain down the right arm and up the right side of the neck, and feelings of pulsation in the root of the neck, where a very deep pulsating swelling could just be felt. Radiography showed a round swelling behind the clavicle, and as is often the case it was difficult to feel sure whether the aneurysm was really arising from the innominate, subclavian, or the common carotid vessel. The inner end of the clavicle was dislocated and the sac exposed, where it was found to be an innominate aneurysm. Any attempt to get below the sac appeared to be exceedingly difficult and hazardous, and it was therefore decided to tie the common carotid and subclavian vessels above the sac. No evil results followed, and when seen a year afterwards the patient appeared well, though she complained of weakness and coldness in the right arm.

ANEURYSM OF THE INTERNAL ILIAC ARTERY

The following is an interesting example of another aneurysm which it is difficult not to regard as the result of a surgical procedure.

CASE 8.—A man, aged 47, was brought to me with vague lower abdominal pain, rectal discomfort, tenesmus, and mucus in the stools. On examining his rectum the finger could hardly be inserted as the whole pouch of Douglas was occupied by a huge round, pulsating swelling. This could just be felt in the suprapubic region, and a systolic bruit could be heard. His Wassermann was negative, but he gave a history that three years before he had had an operation for a fistula-in-ano which was followed by very deep and prolonged plugging. This proved afterwards to have been on the same side as the aneurysm, and it is difficult not to believe that the two were connected and that the internal iliac artery had not been bruised or damaged. A laparotomy was performed,

and the whole pelvis was found to be occupied by a huge sac. Without much difficulty the internal iliac artery, which was abnormally big, was tied above the sac. No untoward results followed, all pulsation disappeared, and a year after the operation the patient appeared perfectly well.

ANEURYSMS OF THE LIMBS

There is little doubt that the commonest aneurysm in the limbs is the popliteal aneurysm, and the second commonest the femoral. These limb aneurysms arise from a number of causes, in which syphilis and injury play a considerable, but by no means universal, part. Continued flexion movements of joints have always been credited with some effect in the causation of aneurysms, while the lodgment of emboli, usually infected emboli, arising in any of the embolus-forming diseases, is by no means an uncommon cause. In elderly men it is not very rare for one or even bilateral popliteal aneurysms to develop gradually and apparently simultaneously without obvious reason.

FEMORAL ANEURYSMS

Excision of the sac of a femoral aneurysm, though not necessarily difficult, is often rendered more or less impossible either by the actual size of the aneurysm or by its extending very high up, in which case a simple ligation of the femoral or iliac artery, just above the sac, is usually successful in stopping the pulsation, and gangrene is unlikely to occur.

CASE 9.—Male, aged 54. Had had disseminated sclerosis for many years, with much crippling and infection of the bladder. Quite suddenly he started pain in the right groin, and a pulsating swelling rapidly started to form in Scarpa's triangle. Within a fortnight the swelling had become very large, the whole thigh and leg dusky red and oedematous, while the swelling pulsed freely, had a systolic bruit, and extended above Poupart's ligament. Whether this was due to an embolism or not is not quite certain, but the pain was so intense and the aneurysm looked so inclined to burst, or at any rate to leak, that something obviously had to be done for it as soon as possible. The external iliac artery was ligatured by the extraperitoneal method, just above the sac. All pulsation and pain stopped at once and within a few days the swelling had diminished to half its size and had become hard, while the oedema and dusky skin of the limb had gone. When the patient left the nursing-home the aneurysm appeared cured.

CASE 10.—Miss D., aged 36, gave a history of ten days' illness with pains in the back and legs, and fever. Four days before a painful swelling had appeared in the left Scarpa triangle, and in the four days this had developed into a large pulsating mass with a systolic bruit which was still increasing rapidly. The heart had a marked mitral murmur, and though it seemed probable that the patient had infective endocarditis, operation appeared urgently necessary. The artery was tied above and below the sac, which was exceedingly adherent. The sac was removed completely, this necessitating removal of a bit of the femoral vein. Healing by first intention occurred and the foot remained quite warm, with good movements. This patient developed hemiplegia six months afterwards and died of infective endocarditis.

POPLITEAL ANEURYSMS

CASE 11.—Mrs. F., aged 25, was admitted six weeks after an apparently septic confinement, with a history of a rapidly appearing, painful swelling in the popliteal space, of a few days' duration. She clearly had a rapidly increasing popliteal aneurysm, while her general condition was good. The sac and artery were exposed, and as it was thought that the condition was probably due to an infected embolus, it was deemed unwise to dissect the sac out, and the artery was tied immediately above the sac. As is often the case in popliteal aneurysms, the condition of the foot gave rise to anxiety for some days, as it remained very cold and blue, but it ultimately recovered, and the patient got about with a weak, but useful, leg.

CASE 12.—Male, aged 70, with atheroma, a low blood pressure, and negative Wassermann. Had had double popliteal aneurysms, one of which extended well up into the thigh, for some years; they were apparently not causing him very much trouble. Early one morning he had sudden pain in the left foot and calf of the leg, while the left foot and leg suddenly became cold, numb, and blue. All pulsation in the left aneurysm ceased. He was brought up to London hurriedly, and it seemed highly probable that an embolus had occurred, and that this could be localised just above the sac of the aneurysm; possibly the clot had swirled up from below. Ten hours after the onset the sac and artery were explored in the hope of removing the clot. The spot where the clot was was easily identified about 1½ inches above the sac; the artery was opened, the clot taken out, and the artery resutured with a watertight suture. Good pulsation returned in the vessel below the suture line; for three days the condition of the foot appeared to improve, but gangrene slowly set in and amputation had to be performed.

This is one of four personal cases of removal of a clot from an artery and suture of the vessel. In two of these the limb afterwards recovered, and in two it became gangrenous.

FEMORAL ARTERIOVENOUS ANEURYSM

Common though arteriovenous aneurysms were during and after the war, they are undoubtedly rare in civil life.

CASE 13.—A man, aged 52, accidentally wounded himself in the left thigh while sharpening a butcher's knife two years before. He had a slight pain in the thigh and a small pulsating swelling could be felt at the centre of Hunter's canal, with a marked thrill and a to-and-fro "machinery" murmur. Very little venous engorgement was present, but the usual cardiac changes seen with an arteriovenous aneurysm—viz., hypertrophy and a systolic murmur—were both observed. Through a long incision over the centre of Hunter's canal the aneurysm was exposed: a small sac was present communicating with both artery and vein; the artery and vein were each tied above and below the communication, and pieces of them, together with the sac, excised. Uninterrupted recovery followed.

OTHER ANEURYSMS OF THE LIMBS

Aneurysms of the smaller vessels of the limbs are by no means uncommon and they are usually the result of trauma, with or without an open wound. In accordance with the general principle already enunciated, the further they are from the trunk the easier they are to cure by operation, and the more likely it is that the radical operation of excision of the sac can be performed. The following are a few instances:—

CASE 14.—A boy, aged 18, had a motor accident and a deep cut on the front of the lower third of the left leg. Two months afterwards he presented himself with a pulsating swelling in this area, about the size of a walnut, and with a systolic bruit. At operation it proved to be sacular aneurysm of the anterior tibial artery which was completely cured by ligature of the vessel and excision of the sac.

CASE 15.—A boy, aged 14, cut his left wrist on some barbed wire and presented himself with a typical arteriovenous aneurysm of the radial artery. There was a pulsating swelling with a thrill and a continuous "machinery" murmur, while the veins round were dilated. Both ends of the artery and vein were tied, and portions of each with the sac were dissected out.

CASE 16.—A girl, aged 20, had stabbed herself in the left forearm with a penknife five weeks before. At the time of admission she had a round, dusky, pulsating swelling near the wound. There was no thrill, but a sharp systolic bruit. The sac was exposed and the radial artery tied above and below it, and the sac then dissected out.

CASE 17.—A girl, aged 18. Since the age of five had had prominent pulsating veins on the back of the right hand and forearm. There was a pulsating swelling over the radial artery at the wrist and another pulsating swelling in the palm of the hand. All the veins of the hand and forearm were congested and pulsating, while there was a thrill and roaring continuous bruit. There was a systolic murmur in the heart, no scar, and no history of injury. Her hand was almost useless. This was thought to be one of the very rare instances of a non-traumatic arteriovenous aneurysm, probably congenital. The radial artery was explored and ligatured above and below the swelling, with a result that pulsation in the veins almost stopped. A year later she stated she was much better, but there was still a large number of pulsating veins and a roaring bruit. The ulnar artery was therefore ligatured just above the wrist. This completely stopped all pulsation and bruit, and the swelling disappeared.

CASE 18.—Mrs. G., aged 50, had for three months noted a small pulsating swelling on the front of the right wrist. She is quite certain there had been no injury. It caused slight pain, had a soft bruit, and was clearly an aneurysm of the radial artery about the size of a large filbert nut. Under a local anæsthetic the artery was tied above and below the sac, and this cured the condition.

The above cases of aneurysms in the limbs exhibit one rather curious phenomenon—namely, that more than half of them were seen in private practice. One would have expected the working-class patient to be the more subject to such injuries.

The important principles in the operative treatment of any aneurysm of this kind consist (a) in not using a tourniquet; (b) in obtaining complete control of the main artery by exposing this some little way above the sac and placing an arterial clamp, or temporary rubber ligature, on it; (c) an attempt should be made if possible to perform a radical excision of the sac. Matas' operations of endo-aneurysmorrhaphy, though excellent in theory, are most difficult to perform in practice. The two instances in which I have attempted it were both failures.

THE USE OF THE COMPLEMENT-FIXATION REACTION IN THE DIAGNOSIS OF HUMAN PSITTACOSIS

By S. P. BEDSON, M.D., M.Sc. Durh., F.R.S.
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON,
AT THE LONDON HOSPITAL

IN the laboratory investigation of a case of suspected psittacosis isolation of the virus should be our principal aim. Virus may be found in the blood or in the sputum and its presence there can be demonstrated by mouse inoculation. Blood is only virulent during the early stages of the disease, whereas the sputum remains virulent over a much longer period and commonly has a higher virus content: it constitutes, therefore, the material of choice (Meyer and Eddie, 1934; Rivers and Berry, 1925). Unfortunately this line of investigation is not always fruitful. Sputum is always scanty in human psittacosis and it may prove impossible to obtain a suitable sample. Further than this, the case may be seen too late for there to be any hope of isolating virus. Hence it is obvious that a serological reaction of diagnostic value would be of the greatest service in the investigation of a case of suspected psittacosis. In a number of virus infections of man neutralising antibody is developed in sufficient

quantity for the neutralisation test to be of use in diagnosis. This is not so in psittacosis (Bedson and Western, 1930; Rivers and Schwentker, 1935), but there is evidence that a specific complement-fixation reaction can be obtained with the serum of individuals suffering from this disease (Bedson, 1933). The probable explanation of these two apparently contradictory observations is that psittacosis virus possesses two antigens each of which excites the production of specific antibody, and that one of these antibodies is responsible for the neutralisation test whilst the other gives the complement-fixation reaction. That a virus may be antigenically complex has been shown in the case of vaccinia (Craigie and Wishart, 1934; Hughes, Parker, and Rivers, 1935) and I have evidence, as yet unpublished, suggesting that the same is true of psittacosis virus. It has now been possible to apply this complement-fixation reaction to a number of sera coming from cases of psittacosis and other conditions and the findings form the subject of this paper.

TECHNIQUE OF THE TEST

The technique is essentially the same as that I use for complement fixation with other viruses and their antisera (Bedson and Bland, 1929). The specific antigen consists of a 5 per cent. suspension of virulent mouse spleen in sterile saline or distilled water, in the latter case made isotonic by the addition of the requisite quantity of 9 per cent. salt solution. Such a spleen suspension when freshly made contains a certain amount of complement and if used in that state will interfere with the accurate dosage of complement in the test. After standing in the refrigerator ($\pm 4^{\circ}\text{C.}$) for a week the bulk of the complement will have become inactive and the suspension will then be available for use, but the fresh suspension can be heated for thirty minutes at 56°C. without destroying its specific fixing power. In actual practice this latter mode of treatment has not been resorted to, since spleen suspensions a week or more old were always available.

The keeping power of these antigens varies considerably. Some will retain their antigenic property unchanged for several months, others will have lost it in as many weeks. It is not known what factor or factors are responsible for this, nor is it claimed that the antigen employed is the best that could be evolved; these are points worthy of further investigation. The anticomplementary activity of the antigen is tested on each day of the test and an antigen is only considered suitable if it does not interfere with the action of 1 M.H.D. (minimum hæmolytic dose) of complement when present in double the dose used in the test. A control antigen consisting of a 5 per cent. suspension of either a normal mouse spleen or the spleen of a mouse inoculated with ectromelia virus is invariably incorporated in the test. The serum under examination is used in dilutions ranging from 1 in 1 to 1 in 8, 0.1 c.cm. of each dilution being employed. In addition to the sera under investigation each test includes a known psittacosis serum and two or more normal human sera. All sera are inactivated at 56°C. for thirty minutes. The dose of antigen is 0.1 c.cm. and 2 M.H.D. of complement are used throughout the test. The usual antigen and serum controls are always included and the volume in each tube made up to 0.8 c.cm. with saline. After 2-3 hours' fixation at room temperature 0.2 c.cm. sensitised cells are added and the test placed in the 37°C. water bath for thirty minutes when the first

reading is taken. A second reading is made after the test has stood at room temperature overnight.

RESULTS

In Table I. are given the results obtained with the sera from cases in which a confident diagnosis of psittacosis had been made on clinical and epidemiological grounds. With the exception of one case, Pz., the findings obtained with the complement-fixation test are in complete agreement with this diagnosis. It is to be regretted that an attempt to isolate virus was not made in every case but this was sometimes unavoidable. Case M. for instance, a patient in Austria, had no sputum at any time, it was, in fact, this feature of the case which led to a sample of serum being sent in for complement fixation. Of those in which sputum gave a negative result three, Lo., Ba., Sf., were patients in the Allgemeinen Krankenhauses S. Georg, Hamburg, under the care of Prof. Hegler, and the sputum was sent for investigation to the Robert Koch Institute, Berlin. The material from Case L. was examined for virus at the London Hospital.

Table II. records the findings with the sera from a number of cases suspected possibly of being psittacosis. Three of these, from patients W., P., and K., were oxalated plasma and such material is definitely inferior to serum for a finely balanced complement-fixation test such as this. A fairly high degree of non-specific fixation may be given by oxalated plasma as is seen from the findings with these three specimens. In the case of patients W. and K. the interpretation of the test is obvious; it is negative. But in Case P. the interpretation is not so clear. However, although the degree of fixation was greater with the psittacosis antigen with this specimen even with the undiluted serum it was not complete, and since a further reading made later in the disease showed no increase in fixing power, it seems probable that the reading of this test as negative is correct. The serum from Case Bl. fixed complement equally well with both specific and non-specific antigen, and apart from the suggestion that this serum was Wassermann-positive—a point which it was not possible to investigate owing to the amount of serum available—the explanation of this finding is obscure. In the remaining seven cases the interpretation of the test is clear. It should be added that in Case Bc. clinical opinion was divided as to the nature of the disease.

The results obtained with a number of control sera are given in Table III. The great majority of these sera were obtained from amongst those sent in for the Wassermann reaction. They were selected after this test had been carried out and those giving a negative reaction deliberately chosen. However, a few positive Wassermann sera were included, since previous experience had shown these to give fixation both with the psittacosis and control antigens.

In no case was the interpretation of the findings with these control sera in doubt. As one might have expected the positive Wassermann sera fixed complement equally well with both antigens, thus revealing themselves and obviating the possibility of their being returned as false positives. They did not all fix complement equally well with these antigens but this was not unexpected; one fixed rather better with the psittacosis antigen than with the control for which it is difficult to assign a reason. It is possible, of course, that, occasionally, a positive psittacosis fixation might be obscured owing to the

patient's serum giving a positive Wassermann reaction, but this would only lead to a false negative finding.

CONCLUSIONS

The evidence, outlined above, shows that the complement-fixation reaction, when suitably carried out, gives valuable assistance in the diagnosis of psittacosis in man. Six of the sera came from cases under the care of Prof. Hegler in Hamburg and the

test was carried out without any further information than that the patients were possibly cases of psittacosis. Comparing the result of the test with the epidemiological findings and his final opinion of these cases clinically, Prof. Hegler has expressed the opinion that the complement-fixation reaction had "ein durchaus sicheres Resultat ergeben." The reaction has been found positive as early as the twelfth day of disease and as late as the fifth week. How long it may remain positive it is impossible to say, but from the findings in Case Be. and from observations made on hyperimmunised guinea-pigs, one would not expect the antibody responsible for this reaction to persist for very long in convalescence. It must be emphasised that the specific complement-fixing power of these human psittacosis sera is of a low order and that in order to detect it a finely balanced test is essential. For this reason rigorous control of the test is absolutely necessary if erroneous results are to be avoided.

I wish to thank Prof. C. Hegler, director of the Allgemeinen Krankenhauses, Hamburg; Dr. E. L. Sturdee, of the Ministry of Health; Dr. A. P. Thomson, of Birmingham; and several of my colleagues at the London Hospital for the supply of sera and information from cases of suspected psittacosis.

ARTIFICIAL PNEUMOTHORAX FOR THE RELIEF OF ACUTE PLEURAL PAIN

By CEDRIC SHAW, M.B. Camb., M.R.C.P. Lond.

PHYSICIAN TO MARGARET-STREET CHEST HOSPITAL; MEDICAL REGISTRAR TO ST. GEORGE'S HOSPITAL; AND CLINICAL ASSISTANT TO THE BROMPTON HOSPITAL

SYMPTOMATIC therapy, so often a *faute-de-mieux* resource, acquires a biological significance approaching that of specific therapy, when, by increasing subjective comfort it removes, in addition, a pathogenic factor of potential danger to life. This generalisation is aptly exemplified by the successful treatment of pleural pain. In the young and robust, the pain of acute pleural inflammation, because of its agonising character, demands relief primarily on grounds of humanity. In the middle-aged or elderly, however, the onus of therapeutic responsibility is greatly augmented by the probable occurrence of the serious results which commonly follow upon failure to confer subjective relief; for in such patients myocardial failure and death may be sequelæ of the restlessness, insomnia, and anoxæmia occasioned by the respiratory pain, whilst the shallow, pain-inhibited respiratory excursion produces a varying degree of pulmonary basal atelectasis, which is the prelude to pneumonic infection and its satellite toxæmia with a predilection for the myocardium and the medullary centres.

Ideally, rational symptomatic therapy should achieve alleviation of a symptom by nullification or attenuation of the physio-pathological mechanism basic in its production. Scientific accuracy of this order cannot be claimed in regard to the symptom of pleural pain; neither the popular theory of friction between inflamed serous surfaces, nor Bray's¹ concept of parietal pleural elastic tension, is universally applicable. But there remains the universally accepted clinical observation that separation of the visceral and parietal pleural layers, whether by fluid or by air, results, without exception, in the disappearance of the pain of acute pleurisy. The methods generally adopted to relieve pleural pain are (1) strapping the affected hemithorax, (2) the application of counter-irritants, and (3) the exhibition of narcotic-analgesic drugs of the opium or barbiturate group. Attempted immobilisation by strapping is only partially effective, and has the disadvantage that it favours the production of atelectasis; it also hampers consistent clinical and radiological examination. The application of counter-irritants results chiefly in the greasy discomfort of the clinician in charge of the case. The exhibition of narcotic-analgesic drugs is indictable on their inefficacy except in doses capable of inducing cardiomedullary depression which expedites the initiation of anoxæmia, atelectasis, and their attendant ills.

Because of its acknowledgedly complete efficacy in relieving pleural pain, separation of the pleural layers, as by an artificial pneumothorax, seems to be the most rational mode of therapy; its employment, though generally recognised in text-books, is mentioned by them only in terms of curt dismissal. The risk of secondary pleural infection, of causing or increasing myocardial distress, and of superimposing the dangers inherent in the induction of pneumothorax—such as pleural shock and air embolism—appear to be the reasons underlying this attitude. They are more theoretical than experiential, and critical examination reveals them as bogies with a very infrequent incidence and therefore of insignificant import when

balanced against the prophylactic value of efficiently abolishing the anguish of respiratory pain with its clinical consequences.

TWO CASES

The following two cases are cited to support the thesis which has been advanced.

CASE 1.—Mrs. A., aged 58, a week previously had been concussed and had fractured her right clavicle; three manipulations under general anaesthesia had been necessary before the fracture had been set satisfactorily. At noon on the day before I was asked to see her, she felt a sudden, acute pain at the angle of the right scapula; a few hours later she began to cough up bright blood-stained sputum; her temperature rose to 100°, her pulse-rate to 104, and her respirations to 28; pulmonary embolism was diagnosed. She became progressively more ill, and I saw her in consultation with Mr. R. Trevor Jones thirty hours after the onset of her pulmonary symptoms, when the physical findings were: temperature 101° F.; pulse 120, regular, thin; respiration 32; blood pressure 140/80. Moderate cyanosis of lips, malar eminences, and ears. Very restless, delusional, and incapable of rational conversation. Respirations shallow, grunting, and obviously painful. Looks desperately ill. Area of cardiac dullness and heart sounds normal. Diminished movement of right lung base with a large area of dullness, faint bronchial breath sounds, and a pleural rub below the angle of the scapula. Sputum muco-purulent with much bright red blood.

On the history and these findings I concluded that she had developed an atelectatic pneumonia secondary to acute respiratory pain from the pleurisy overlying the area of embolism. It was obvious that the prognosis was extremely grave. Because of the danger of morphia or other narcotic analgesics in adequate doses, to a patient as ill and as old as she, I decided to induce a shallow pneumothorax to relieve the pleural pain, and 250 c.cm. of air were injected without distressing her. The only other treatment prescribed was an expectorant mixture and four-hourly brandy.

Within an hour of the induction her respiratory rate fell from 32 to 20, and she breathed and coughed without distress. Ten hours later—during most of which time she had slept soundly—the clinical picture was surprisingly changed. She was rational, alert, completely comfortable, and not at all cyanosed; her temperature was 100°; her pulse and respiration-rate 94 and 22 respectively. A faint pleural rub had reappeared at the right base, so she was refilled with 200 c.cm. of air. No further refills were given, and, apart from an evening rise of temperature to 99° for three days, she convalesced and recovered completely without incident.

A skiagram of her lungs taken a fortnight later showed pleural thickening at the right base with woolly parenchymal shadowing suggesting unresolved pneumonia. These appearances eventually disappeared completely.

CASE 2.—Mr. B., aged 70, had fractured three lower left ribs 48 hours before I saw him in consultation with Dr. G. N. Grose; for 24 hours he had been coughing and complaining of extreme respiratory pain at the left base. He had suffered from essential hypertension for 18 years and recently had manifested symptoms of myocardial inefficiency. The physical findings were: temperature 99°, pulse 80, respirations 24, blood pressure 170/90 (before this illness usually 200/100). Looks very distressed and ill; slight malar and labial cyanosis. Area of cardiac dullness increased moderately downwards and to the left; mitral first sound prolonged and low-pitched; aortic second sound accentuated. Left base immobile; large area of dullness behind with faint broncho-vesicular breath sounds and a coarse pleural rub.

For 24 hours conservative measures, including diathermy of the chest wall, were resorted to. But his general condition deteriorated and his cardiopulmonary symptoms exacerbated; he was very restless and grossly cyanosed, his breathing was acutely painful, and he had frequent agonising paroxysms of cough which produced purulent nummular sputum; his temperature (morning) was 97°, pulse 120, respirations 36. The physical signs

at his left base were unchanged; it was plain that he had developed an atelectatic pneumonia.

The prognosis seemed almost indubitably fatal; narcotic analgesic drugs were definitely dangerous to use. Persuaded by these considerations and by the memory of its therapeutic value in Case 1, I decided to induce a shallow pneumothorax; 250 c.cm. of air were injected. The almost immediate change in his state was spectacular; he breathed and coughed painlessly and his cyanosis became only slight. Eight hours later his temperature was 99° F., pulse-rate 108, and respirations 20; he was breathing and coughing without distress and he was not cyanosed. The prognosis had altered completely. Two hours later and 24 hours after this there was a recrudescence of his previous symptoms, with a rising pulse and respiratory rate and return of a faintly audible pleural rub. On both occasions immediate relief followed a refill with 200 c.cm. of air. No further refills were given. He convalesced rapidly, and his cough and purulent sputum had disappeared by the ninth day of illness.

COMMENT

These two case-histories have many common features. In each case the patient was elderly and had developed an atelectatic pneumonia because of the shallow breathing necessitated by the pain of acute pleurisy coupled with compulsory adoption of the supine posture (vide Briscoe²); in Case 1 the correctness of the diagnosis was supported radiologically; in both cases the anoxaemia consequent upon shallow breathing and partial pulmonary atelectasis, added to the toxæmia of secondary pneumonic infection, compelled a prognosis of death from cardiomedullary depression. But in both cases the induction of a shallow pneumothorax produced a dramatic metamorphosis of the clinical and prognostic picture, by its relief of respiratory pain, and so of the anoxaemia and atelectasis; moreover, in each case the amount of air sufficient to give relief was too small to be capable of causing myocardial embarrassment. The employment of artificial pneumothorax for acute dry pleurisy has theoretical sanction because of its accepted efficacy in removing the respiratory pain, especially since it thus minimises the possible sequential dangers facing the patient. The two cases detailed show that this theoretical sanction is supportable by practical experience.

The general circumstances indicating the therapeutic employment of pneumothorax for pleural pain have been considered. In post-operative cases in which an abnormally initiated diaphragmatic paralysis enhances pulmonary basal atelectasis its value seems worthy of further research. Coghlan³ in this country and many foreign observers have advocated lung collapse for the treatment of lobar pneumonia; but despite the striking support given to them by the experimental studies of Lieberman and Leopold⁴ their advocacy has not found general favour, chiefly because of a theory based clinical timidity. Whatever the theoretical objections to the induction of major lung collapse in lobar pneumonia, there can be few or none to a consideration of the pain-removing, comfort-giving injection of the innocuously small amount of air necessary to produce pleural separation in those early days of the disease in which the ultimate prognosis is influenced by the degree of general and myocardial exhaustion to which the patient is subjected. Taylor⁵ has testified in support of this contention.

SUMMARY

1. The pain of acute dry pleurisy demands removal in young patients on humane grounds; in the elderly

this is imperative as a prophylactic measure against the occurrence of anoxæmia and atelectatic pneumonia which is so often fatal.

2. The therapeutic methods in general use are either only very partially effective or dangerous.

3. The induction of a shallow pneumothorax invariably relieves pleural pain and so removes anoxæmia and atelectasis. The amount of injected air necessary is so small as to be quite harmless.

4. Two cases are detailed in which atelectatic pneumonia and anoxæmia, secondary to pleural pain, suggested a fatal prognosis. Dramatic recovery followed the induction of an analgesic pneumothorax.

5. The indications for the employment of pneumothorax to relieve acute pleural pain are discussed.

ARTIFICIAL PNEUMOTHORAX IN THE MANAGEMENT OF LOBAR PNEUMONIA

By WM. EGBERT ROBERTSON, M.D.

CHIEF OF ONE OF THE MEDICAL DIVISIONS OF THE GENERAL HOSPITAL, PHILADELPHIA, PA.

PNEUMOTHORAX as a spontaneous disease has been recognised definitely since the time of Riolan¹ (1648). The first purposeful attempt experimentally to produce pneumothorax in animals is ascribed to Hewson² (1767). Forlanini³ is credited as the first to employ artificial pneumothorax clinically in 1882. The application of this procedure as a therapeutic measure in pneumonia was due to Friedemann⁴ in 1921, but the appearance of Coghlan's⁵ paper in 1932 served to reawaken interest in this measure. In 1932 two cases of lobar pneumonia were given artificial pneumothorax in my service at the Philadelphia General Hospital, and in 1933 I suggested a more extensive clinical application. About this time Liebermann and Leopold⁶ reported their experimental studies upon dogs with induced pneumonia, including one case of lobar pneumonia in a man aged 44, who responded promptly and favourably to artificial pneumothorax. They were able to collect no more than 50 cases reported in the literature before 1934, with 47 recoveries and 3 deaths. Many of these cases were children in whom mortality from lobar pneumonia is admittedly low.

At the Philadelphia General Hospital (of 2500 beds) we deal with the poorer strata of society, among whom ignorance, neglect, and economic stress are perennial. The mortality-rate in lobar pneumonia under such conditions must be high. Hence our desire to observe the effect of artificial pneumothorax. This was administered to 47 cases: 27 whites with a case-mortality of 37 per cent., 20 negroes with one of 50 per cent. mortality, total death-rate 43 per cent. The number of refills varied from two to eight, an average of 400 c.cm. being given each time. We carefully avoided the induction of a positive pressure, although there is some evidence in support of that as a preferable procedure. Under the conditions as stated, we never observed any influence upon venous pressure, determined intra-

venously, and no appreciable influence upon the blood pressure.

Summarising our 47 cases, there were 39 males and 8 females, ranging in ages from 23 to 65 years, and one case 15 years of age. Twenty-four were admitted from the fourth to the sixth day of the disease, nine at an indefinite period, ten on the second day, and four on the first day. The types were 1 and 2 and group IV. Only one developed empyema. Several had an effusion, but in no instance could fluid be ascribed to the pneumothorax. Three died in less than twenty-four hours after admission. One of these, a negro, aged 26, was found post mortem to have nephrotic kidneys and fatty degeneration of the liver. The only one to develop empyema was a white man of 46 who had a mitral regurgitation, an enlarged liver, a 4 plus Kahn, also 4 plus with all antigens. He was a type 1. He recovered from pneumonia, but died three months and nine days after admission, having undergone several operations for empyema. A luetic negro of 32 had hypertrophy of the left ventricle and vascular disease, and had been ill for two weeks before admission. He died four days later.

In a previous paper Dr. H. F. Robertson and I⁷ called attention to lues as a factor in unresolved pneumonia. What influence syphilis has upon the course of pneumonia I am unable to state. Several of our fatal cases were syphilitic, but some of those who recovered also had strongly positive Kahn and Wassermann reactions. However, the influence of this infection in causing delayed resolution in pneumonia seems definite, though no case presented among the pneumothorax group.

One very obese, white man of 26, a post-encephalitic with a Parkinson syndrome who had had bulimia and still had polydipsia and polyuria, died on the fifteenth day of the disease, seven days after admission. Two had fibrillation on admission. One of these was jaundiced. One negro of 54 had been ill in bed four weeks, attended only by neighbours before admission. He had a right upper lobe lesion when brought in, but he died of a pneumococcus meningitis (group IV.) sixteen days after admission. A white man, aged 65, an indigent, had been ill for five days in the city shelter and died two days after admission.

If we exclude the ten cases briefly referred to above, there remain 37, with 10 deaths, a mortality of 27 per cent. This seems justifiable. It was less an error of judgment in including them originally than a desire to study the effect of artificial pneumothorax on all of the cases of lobar pneumonia admitted to the wards in a certain period of time. Many of the cases reach our institution after suffering more or less neglect and privation. Selection of cases may seem more appropriate than the elimination of those manifestly unfit for any reason. In omitting ten of the series, we have, at the same time, endeavoured to portray the results obtained under both conditions. We are continuing our observations. A much larger experience will be necessary before a really valid opinion can be expressed, despite the strikingly favourable results obtained by Lieberman and Leopold in experimentally induced pneumonia in dogs.

Although theoretical arguments might be marshalled, we have not been able to conclude that pneumothorax is of real practical value in the treatment of pneumonia. It does confer almost instant relief upon those suffering from coincident pleuritis, but it does not cut short the attack of pneumonia. Frequently, too, it ameliorates cough and expectoration. It seems equally definite that it is innocent of any collateral ill-effects. It frequently lowers the temperature level, sometimes to a surprising extent, and when marked the fall is accompanied by profuse

sweating. These pseudocrises are less uniformly accompanied by a subjective sense of well-being than one sees when a foreign protein is given by vein, especially when a protein shock reaction is given before the end of the third day of pneumonia. In both instances, however, the physical signs pursue an uninterrupted course.

The scope of this paper precludes more than a brief reference to the Schilling count. Dr. Walter Crocker and Dr. Eleanor H. Valentine, the latter a former interne at the Philadelphia General Hospital, have added materially to the Schilling method and extended its usefulness by what they have termed the shiftogram; of evil portent is a sharp shift to the left, when both myelocytes and juveniles escape into the blood stream. It only remains for me to add that a careful study of the staining properties and the architecture of the leucocytes often furnishes a basis of prognostic value.

I desire to extend my sincere appreciation to my colleagues on the medical staff for permission to include their cases, to Dr. John A. Wagnetz and to Mrs. Wagnetz for their aid in the compilation of statistical material, and to my internes, Drs. Roscoe B. G. Cowper, Albert Behrend, and Vernon L. Tuck for their untiring efforts.

HUMAN ANTHRAX IN BAROTSELAND TREATED WITH NOVARSENO BENZENE

By F. W. GILBERT, M.B. Lond., D.T.M. & H.

GOVERNMENT MEDICAL OFFICER, MONGU, NORTHERN RHODESIA

HUMAN anthrax is a comparatively rare disease; it is more or less confined to certain localities, and to a certain section of the population. The pustular lesion, on both white and black skins, is very characteristic, and once seen will never be mistaken for anything else.

Among the cattle-owning Marozi natives of Northern Rhodesia, especially among those who live in the upper Zambesi valley (Barotse plain) anthrax is not uncommon, and has a high fatality-rate. These natives live with their cattle out on the plain during the dry season, June to December, and as the flood waters of the Zambesi gradually inundate the plain, so the natives retreat with their cattle to the higher bush country. The spores of *Bacillus anthracis* must be present in the soil of the plain, where the cattle have grazed for years, and with the advent of the rainy season, conditions for the germination of these spores are favourable; cases of anthrax, both human and bovine, occurring after the commencement of the rains. Human infection is almost always due to the use of infected hides as clothing or bedding; the spores remaining quiescent until the advent of the favourable rainy season conditions.

It is difficult to substantiate the natives' reports, but, as far as can be gathered, during December, 1933, and January, 1934, there were 25-30 cases of

human anthrax within a radius of 20 miles of Mongu, the administrative centre of Barotseland. It was said that almost every patient died, and we may take it that the mortality was over 60 per cent. The disease was of the "malignant pustule" type, but it was learned on questioning that there had also been several deaths from what appeared to be an acute hæmorrhagic gastro-enteritis, death invariably occurring within 24 hours of the onset. These were quite probably cases of intestinal anthrax, due to ingestion of infected meat.

In January, 1934, an outbreak of what turned out to be anthrax was reported by one of the petty chiefs, and instructions were given that all human cases were to be brought into hospital; while instructions with regard to the control of the disease in the affected village were also issued. Previously no cases of anthrax had been treated in hospital, nor, so far as can be ascertained from past records, had they been seen or diagnosed by the medical officer, stationed at Mongu.

Four cases of anthrax were brought to hospital during the months January-April, 1934, and 5 more during the months December, 1934-February, 1935. These 9 cases were all treated in Mongu Hospital. In each of them smears were made from the fluid in the surrounding vesicles, or if these had coalesced from the tissues underlying the slough; these smears were stained with Gram's stain and all showed *B. anthracis*, scanty in some, profuse in others.

The only treatment given, apart from boric fomentations locally, was novarsenobenzene (nearsphenamine) intravenously, or a similar preparation, sulpharsenobenzene (sulpharsphenamine) intramuscularly. One injection of 0.6 g. was usually found sufficient, but if the œdema persisted after 24 hours a second was given. In every case this œdema—which had been severe and likely to cause death in 3 of the patients—was relieved in 36 hours, and had disappeared in four days. The temperature subsided, after an initial rise, and was normal in five days. Clinically all the cases (except No. 5, one of the two which proved fatal) were much improved in 24 hours, and apart from the resulting ulcer, with its sloughing centre, the 7 patients who recovered were perfectly fit and ambulatory on the sixth day. After the slough had separated, the ulcer was covered with adhesive plaster and left for a week; the plaster was then renewed, and at the end of three weeks or a month the patient was discharged with a pink though rapidly browning scar.

THE NINE CASES

CASE 1.—Female, aged 16. First seen and admitted to hospital on Jan. 6th, 1934. Pustule of two days' duration, situated over the right scapular region. The black centre of the pustule was $\frac{3}{4}$ in. in diameter; there was a surrounding erythematous zone with vesicles containing yellowish fluid, and a brawny œdema extending 3 in. from the centre of the pustule. Films made from the fluid in the vesicles showed *B. anthracis*, mostly in short chains of three or four bacilli. On admission the temperature was 100.2° F.; pulse-rate, 96. Neokharsulphan 0.3 g. was given intramuscularly, the dose being repeated on Jan. 7th. Œdema was considerably less on the 8th, but the temperature was still 100°. After injection of novarsenobenzene 0.3 g. intravenously on the 9th there was no further rise of temperature, and the œdema was gone by the 10th. No more treatment was given except the application of adhesive plaster to the resulting ulcer, after the separation of the slough on Jan. 12th. The ulcer healed by the 25th and the patient was discharged.

CASE 2.—Male, aged 18. First seen and admitted to hospital on Jan. 12th, 1934. Anthrax pustule of three

days' duration, situated on the left side of the face over the angle of the jaw; much œdema, especially of the neck, causing respiratory embarrassment. Temperature, 102.6°; pulse-rate, 110; respirations, 35. Scanty *B. anthracis* present. On Jan. 12th novarsenobenzene 0.6 g. was given intravenously. On the 13th œdema was much less; temp., 102.4°; pulse, 90; resp., 25. On the 14th œdema was again less; novarsenobenzene 0.3 g. was given intravenously. By the 15th œdema had gone (temp., 99.8°; pulse, 80; resp., 18) and on the 16th the patient was quite fit, save for a sloughing ulcer at the site of the pustule. Plaster applied over ulcer on Jan. 19th and the patient was discharged on Feb. 9th with the ulcer fully healed.

CASE 3.—Male, aged 15. First seen and admitted to hospital on Feb. 3rd, 1934. Anthrax pustule of two days' duration near the outer canthus of the left eye, which

23.12.34 S.v.34
Photographs of the patient in Case 4 showing cure of large anthrax pustule on right cheek.

was quite closed by œdema extending all over the left side of the face and neck. Temperature, 104°; pulse-rate, 120; respirations, 32. *B. anthracis* plentiful in fluid from vesicles. On Feb. 3rd novarsenobenzene 0.6 g. was given intravenously. Next day the œdema was much less (temp., 101°; pulse, 84; resp., 20) and on the 5th it had almost gone (temp., 99°). By the 6th there was no œdema and the patient was quite fit. Plaster was applied on the 11th and he was discharged, with the ulcer healed, on the 24th.

CASE 4.—Male, aged 17. First seen on April 23rd, 1934. Anthrax pustule of three days' duration situated near the outer canthus of the right eye (Fig. 1). Much œdema of the eye, face, and neck; vesicles surrounding the pustule beginning to break down. Temperature, 101°; pulse-rate, 90; respirations, 28. *B. anthracis* scanty in scrapings. This patient had novarsenobenzene 0.6 g. intravenously on the 24th, and by the 26th his œdema had gone and he was quite well. On May 1st plaster was applied to the ulcer, and on the 20th the ulcer had healed and the patient was discharged. Fig. 2 shows the condition on May 8th.

CASE 5.—Male, aged 1 year. First seen and admitted to hospital on Dec. 7th, 1934, with an anthrax pustule of five days' duration situated on the chest near the left breast. The child was obviously very ill; temperature, 100; pulse-rate, 160; respirations, 40. *B. anthracis* was present in tissues round the pustule, and there was considerable œdema of the chest wall. No veins could be located, so sulpharsenobenzene 0.15 g. was given intramuscularly. The child died three hours after admission. No post-mortem was allowed by the parents, but death was obviously due to toxæmia.

CASE 6.—Male, aged 5. First seen and admitted to hospital on Dec. 19th, 1934, with an anthrax pustule of

two days' duration situated on the left side of the neck; much œdema of the neck and chest wall. Temperature, 101°; pulse-rate, 140; respirations, 36. *B. anthracis* very plentiful in the surrounding vesicles. On Dec. 19th novarsenobenzene 0.3 g. was given intravenously. Next day the œdema was less, but the temperature was up to 103.8°; so a further 0.3 g. was given intravenously. On the 21st the child was much better (temp., 99°; pulse, 100; resp., 30). On the 22nd however he developed abdominal ascites which increased until the abdomen was greatly distended. Weakness increased and death occurred on the evening of the 23rd. Possibly the ascites was due to overdosage with N.A.B. There was no jaundice. No post-mortem was allowed.

Following closely on Case 5, which was rapidly fatal owing to treatment being so long delayed, Case 6 was unfortunate. It was thought wise to give massive treatment before the toxic effects of the disease had got the better of the child's constitution, but this child might have recovered if the second dose of novarsenobenzene had not been given.

CASE 7.—Male, aged 25. First seen and admitted to hospital on Dec. 29th, 1934. He had two anthrax pustules, one of two days' the other of three days' duration; one was situated on the right side of the face on the angle of the jaw, the other on the left side of the forehead. There was a great deal of œdema, especially on the right side of the neck, causing difficulty in breathing. Temperature, 100°; pulse-rate, 130; respirations, 30. The first dose, on Dec. 29th, was novarsenobenzene 0.6 g. intravenously; the temperature rose to 103° that evening, but the pulse-rate dropped to 120. On the 30th the œdema was less (temp., 101°; pulse, 100; respirations easier). Next day the œdema was less again (temp., 99°; pulse, 90). By Jan. 1st all the œdema had gone; the temperature was normal and the pulse-rate 84. On the 2nd the patient was quite well and the sloughs separating. Plaster was applied to both residual ulcers on the 5th, being removed and reapplied on the 15th. The ulcers had healed on discharge on the 28th.

CASE 8.—European male, aged 40. First seen on Jan. 30th, 1935. Large anthrax pustule of three days' duration on the flexor aspect of the left wrist. This trader owns and handles numbers of cattle, and each year loses a few from anthrax; though he did not suspect that this "sore" was anthrax. He was treated as an out-patient. When he was first seen the temperature was 102° and the pulse-rate 110; there was considerable œdema extending from the wrist and hand to the shoulder, but no axillary adenitis. On Jan. 30th he had novarsenobenzene 0.6 g. intravenously, and on the 31st the œdema was reduced though the temperature was up to 102.4°; pulse-rate, 104. On Feb. 1st a further intravenous injection of 0.6 g. was given and by the 3rd the œdema had gone and the temperature and pulse were normal. Plaster was applied on Feb. 8th and the ulcer had healed by March 5th.

CASE 9.—Female, aged 50. First seen and admitted to hospital on Feb. 5th, 1935. There was an anthrax pustule of two days' duration on the left side of the neck; also a great deal of œdema around the neck and on the left side of the face. Temperature, 102°; pulse-rate, 110. She was given novarsenobenzene 0.6 g. intravenously on Feb. 5th and the œdema was almost gone by the 7th, the temperature being normal. Œdema had disappeared on the 8th and the patient was fit, save for the resulting ulcer. Plaster was applied to it on the 11th and renewed on the 20th. The patient was discharged on March 2nd, the ulcer having healed.

RÉSUMÉ

Nine patients with pustular anthrax were treated with novarsenobenzene (neovarsphenamine) only. Seven of them made remarkable recoveries; the other two, aged 1 year and 5 years, died. The first of these, Case 5, was only brought to hospital on the sixth day of the illness, and was moribund on admission. The second, Case 6, responded to

the second dose of novarsenobenzene, but developed a fatal ascites probably due to the toxic effects of this drug on the liver. The number of cases is too small to allow of comparison with other methods of treatment, but the results suggest that novarsenobenzene, if given within four days of the appearance of the pustule, will almost certainly cure the disease.

I am indebted to the acting director of medical services, Northern Rhodesia, for permission to publish this paper.

TREATMENT OF HÆMORRHAGIC DISORDERS WITH VITAMIN C

By H. ENGELKES, M.D.

It is only a few years since Szent-Györgyi isolated ascorbic acid (vitamin C) in crystalline form, and most attempts to use this substance in clinical practice have been concerned with scurvy, which is due to a primary deficiency of the vitamin. If the administration of pure ascorbic acid were limited to this condition we should not often need to use it, especially as fresh fruit juices already provide a remedy. But the real importance of Szent-Györgyi's discovery, from the clinical standpoint, lies in its application to so-called conditioned scurvy. One speaks of a conditioned deficiency when an intake of vitamins sufficient for a normal person proves insufficient because of abnormal conditions in the body. These conditions may be very various, including inadequate absorption, destruction by intestinal bacteria or by a general infection, and perhaps too rapid excretion by the kidneys. Endocrine disturbances also may sometimes play a part.

We are only at the beginning of our knowledge of this conditioned scurvy, and we owe a debt to Stepp and his co-workers who have given an impetus to its clinical investigation. At the Congress of Internal Medicine at Wiesbaden in 1934 Stepp,¹ after pointing out that the typical symptoms of frank scurvy are hæmorrhages and alterations in the bones and teeth, reported results he had obtained at Munich by the treatment of other hæmorrhagic disorders with ascorbic acid. His co-workers, Böger and Schröder, had observed that in such disorders the amount of plasma protein is decreased, the decrease being greater in the albumin than the globulin; in other words, the albumin-globulin ratio is lower than normal. When ascorbic acid was injected the findings were reversed, and this led them to give ascorbic acid to a patient with hæmaturia, with the result that it disappeared at once. The same favourable effect was seen in a case of Henoch's purpura. Stepp also pointed out that the oral administration of the vitamin sometimes does not help either because it is disintegrated in the small intestine, or because in these patients absorption is interfered with.

In August, 1934, Böger and Schröder² reported fresh discoveries. They succeeded in stopping alarming intestinal hæmorrhages in a patient with hæmophilia; and in a case of essential thrombopenia, two days after injections began, they saw the skin and mucous membrane hæmorrhages stop, the urine being free from blood another two days later. The bleeding-time was reduced, the thrombocyte count rose, and the protein content and albumin-globulin ratio of the plasma were increased. Hæmorrhage stopped long before the number of blood-platelets

rose appreciably, and from this it could be deduced that reduction in platelets is not the only decisive factor in the causation of hæmorrhages—others perhaps being alterations in the plasma or in the permeability of the capillary walls. Lastly, they suggested that in bleeding from other causes (icterus, hæmorrhages from uterus, stomach, or kidney) ascorbic acid might be of service.

Shortly afterwards I was in the position to treat a serious case of essential thrombopenia successfully by this method,³ while Vogt⁴ has reported good results both in thrombopenia and in gynæcological hæmorrhages. Having since had further success in cases of hæmorrhagic disorder, I propose to report them briefly. The three summarised below were seen in private practice and form an unselected series.

Description of Cases

I. ESSENTIAL THROMBOPENIA *

A woman 64 years old, operated on ten years ago for stone in the ureter and now suffering from gall-stones, was troubled in February, 1934, with profuse nose-bleeding, for which the rhinologist could find no local cause. The blood was not examined and after a few weeks the bleeding ceased, only to return, however, in November, 1934. She then had gall-stone colic, and a week later skin hæmorrhages and sore spots in the mouth; on Dec. 13th hæmaturia and melæna began. When I saw her on Dec. 17th the skin showed hæmorrhages of various sizes and forms: there were petechiæ, ecchymoses, bruises on the neck, face, and extremities, and to a less extent on the trunk. The inside of the cheeks, the palate, and the underside of the tongue also showed blood effusions. In the mouth there were here and there superficial epithelial defects. There were no hæmorrhages in the fundus oculi and the vitreous. The urine seemed to be pure blood; it did not contain any glucose in demonstrable amount. The faeces were tarry.

The liver and spleen could not be felt. The region of the gall-bladder was tender to pressure. The temperature did not rise higher than 37.8° C. (100° F.) rectally. The blood pressure was 270 systolic and 130 diastolic. Blood examination: hæmoglobin 90 per cent., erythrocytes 4,700,000, leucocytes 6000, thrombocytes 3000, bleeding-time (Duke) 10 minutes. In the blood smear no blood-platelets were seen, only some large forms of thrombocytes. For the rest no abnormalities were found in the blood film. The blood-clot did not contract in the least. Plasma

Course of Case I

Date.	Bleed- ing- time.	Throm- bocytes	Albu- min.	Globu- lin.	Alb.- glob. ratio.	Treatment.
			g. per 100 c.cm.			
Dec. 14	10 min.	3,000	3.67	1.65	2.22	150 mg.
" 19	6 "	"	—	—	—	150 mg.
" 21	3 "	12,000	—	—	—	150 mg.
" 24	1 1/2 "	56,400	3.80	1.65	2.30	150 mg.
" 27	1 1/2 "	360,000	—	—	—	200 g.

						ceblon.
						orange juice.

proteins: albumin 3.67 g. per 100 c.cm., globulin 1.65 g., albumin-globulin ratio 2.22. Wassermann reaction negative.

The diagnosis was acute exacerbation of chronic essential thrombopenia, hypertension, and cholelithiasis. The very high blood pressure was a contra-indication to splenectomy; for when a splenectomy has unfavourable results, it is often due to circulatory disturbances. Hence it was decided to commence treatment with vitamin C. Ascorbic acid (in the form of Cebion, Merck) 150 mg. a day was injected intravenously and the result was surprising (see accompanying Table). After only two days' treatment there were no new hæmorrhages in the skin

* This case has already been reported.³

and mucous membranes, though the urine still contained much blood. After four days the urine was very much clearer, the bleeding-time had fallen to 3 minutes, and the number of blood-platelets was only 12,000. After six days the urine was clear, and after seven days it contained no albumin and the sediment no erythrocytes. The bleeding-time was now $1\frac{1}{2}$ minutes, the number of thrombocytes being 56,400; in the incubator the blood-clot retracted after 15 minutes. Meanwhile the blood pressure had dropped to 180 mm. systolic and 80 mm. diastolic. After nine days the number of blood-platelets was 360,000, and during the rest of the time the patient was under observation this figure remained the same, while the bleeding-time remained about $1\frac{1}{2}$ minutes.

After cebion had been given intravenously for ten days, it was stopped and 200 c.cm. orange juice was given by the mouth. This contains about 100 mg. ascorbic acid, whereas according to Szent-Györgyi a grown-up person only needs about 50 mg. a day. Later in the illness the patient had another attack of gall-stones; the temperature rose to 38.3°C . (100.9°F .) rectally and there was a trace of bilirubin in the urine. This attack passed after two days; she was given Urotropine and the temperature became normal. In order to prevent a relapse of the hæmorrhagic condition I went on giving ascorbic acid orally and the patient took a few oranges every day or tablets of ascorbic acid. She is now apparently well.

Certain observations may be made on this case. (1) Although spontaneous recovery is a possibility, it is remarkable that after two days no new hæmorrhages occurred and after six days the urine contained no more blood. (2) The very long bleeding-time (10 minutes) fell within a few days to 3 minutes, and after seven days to $1\frac{1}{2}$ minutes, remaining as short as that after the medicament had been stopped for several weeks. (3) The number of blood-platelets rose in ten days from 3000 to 360,000. (4) After only a few days the blood-clot retracted normally. (5) During treatment the high blood pressure fell considerably, but one cannot say how far the fall is permanent or due to the vitamin treatment. Ascorbic acid—but only in very large doses—is said to reduce the blood pressure of animals.

II. PURPURA INFECTIONOSA

A boy, aged 15, became acutely ill on March 10th, 1935, with high temperature, headache, joint pains (especially in elbows and knees), and vomiting. Further there was purpura over the whole body, chiefly on the extremities and abdomen, but also on the face; on the thighs were large ecchymoses. He had epistaxis but no bleeding of the gums, or hæmaturia, or melena, or sore-throat. He was continuously delirious, had incontinence of urine and faeces, and a rectal temperature of 40°C . (104°F .). The pulse was small and its rate 140. The lymph glands were not swollen, and there was no œdema. No abnormalities were found in heart or lungs, and the spleen and liver were not palpable. The left knee was much swollen with effusion of fluid, and very painful, several other joints being also affected. The urine contained a trace of albumin and hyaline casts; no sugar and no blood-cells. Blood: hæmoglobin 85 per cent., erythrocytes 4,200,000, leucocytes 14,000, thrombocytes 128,000, bleeding-time 3 minutes, morphological picture normal.

Cebion 150 mg. was given intravenously each day, and after three days, though the temperature was just as high, no new hæmorrhages appeared and the old ones were quickly absorbed. The general condition was much better. The boy complained, it is true, of pain in the joints, but he had become psychically normal and the incontinence and vomiting had stopped. After that the vitamin was given by mouth (150 mg. daily). At the same time 2 g. of aspirin a day was administered. The temperature dropped during the following days, the joints gradually became less painful, and after four weeks the patient had recovered and was discharged.

This was a serious case of purpura infectiosa, in which the hæmorrhagic manifestations disappeared

and the general condition improved under treatment with vitamin C. The fever and polyarthritis, however, were not noticeably influenced.

III. ESSENTIAL HÆMATURIA

A woman of 23, before her illness a nurse, has the following interesting history. Up till Nov. 28th, 1932, she was healthy, but then she suddenly developed hæmaturia; the urine seemed to be pure blood. This condition lasted a week after which the hæmaturia almost (but not quite) disappeared. She had some hæmaturia up to March, 1935—i.e., for $2\frac{1}{2}$ years; though its intensity was very variable blood could always be seen under the microscope, and there were several serious attacks (Nov. 28th to Dec. 5th, 1932; August 11th to 25th, 1933; April 17th to the middle of June, 1934; Dec. 4th to 18th, 1934; Jan. 30th to middle of February, 1935; and March 1st to 15th, 1935). As I have said, these attacks were merely the exacerbation of a continual hæmaturia lasting $2\frac{1}{2}$ years. In the course of this time she had right-sided pleurisy, lasting about five weeks, and radiograms taken afterwards showed a decreased mobility of the right half of the diaphragm, and an old tuberculous focus in the middle lobe of the right lung. Because of this pleurisy she spent the first half of 1934 in a sanatorium, and there she had an "attack" of hæmaturia lasting two months. Menstruation was normal all the time, and she never had bleeding from the nose, gums, skin, or intestines.

Repeated urological examinations were made, both during and between attacks of hæmaturia, and no abnormalities were ever seen in the bladder wall; no tuberculosis, no papillomata, and no stones. Out of both the ureters spouted urine containing blood but free from tubercle bacilli or other bacteria. Indigo-carmin was excreted on the left side after 8 minutes, and on the right side after 10 minutes. During the attacks the urine from both ureters looked like pure blood. The pyelogram was normal on both sides, and no stones were visible. The patient had always taken fruit and vegetables in the food; she had never had a special diet, so that there was no question of a primary deficiency.

She was admitted to hospital on March, 4th, 1935, during an attack of hæmaturia. She looked quite healthy and physical examination revealed no abnormalities in heart, lungs, or other organs, apart from the limitation of movement of the lung border on the right side, due to the pleurisy. The urine contained much blood, and no sugar; the blood-urea was 35 mg. per 100 c.cm.; Ambard's constant was 0.08 (normal); and the dilution- and concentration-power of the kidney was normal. Blood: hæmoglobin 100 per cent., erythrocytes 5,500,000, leucocytes 6000 (normal formula), thrombocytes 487,000, bleeding-time (Duke) 1 minute. Plasma proteins: albumin 3.98 g. per 100 c.cm., globulin 2.14 g., ratio 1.85.

A diagnosis of essential hæmaturia was made and the patient was given ascorbic acid intravenously (Redoxon, Hoffmann-La Roche); during the first six days she had 100 mg. daily and after that 200 mg. in single doses. During the first six days the decrease of blood in the urine was scarcely perceptible; but after that the hæmaturia quickly diminished, and after ten days no erythrocytes could be found microscopically in the sediment. The albuminuria, however, had not yet disappeared. Redoxon was given intravenously for a further six days, and then in doses of 200 mg. a day orally till May 25th; after that she had 100 mg. daily by mouth. No more erythrocytes were found on microscopical examination of the urine except on one occasion after a wound with the catheter. The albuminuria had soon disappeared. For the sake of certainty she is still taking 100 mg. ascorbic acid daily by mouth to prevent a relapse; but after $2\frac{1}{2}$ years' invalidism she is now once more fit for work.

Summary

In the above cases the favourable results obtained in Stepp's clinic were repeated. In none of them was any remedy given apart from ascorbic acid, except in Case III., where the patient had salicylates after the hæmorrhages had disappeared. In all three

cases the administration of ascorbic acid was followed by rapid improvement, and it caused no unpleasant symptoms.

Additional Note

I have since seen two other cases in which the same treatment proved successful.

A woman of 70, who suffered in 1932 from carcinoma of the uterus, was irradiated for that reason with radium. She recovered and was in good health up to June, 1935. She then had an intensive hæmaturia and several ecchymoses (some the size of a fist) on the legs. Rumpel-Leede's sign was positive. Physical examination revealed no abnormalities in the chest or abdomen. The blood pressure was 190 systolic and 100 diastolic. Cystoscopy revealed no alterations of the bladder, and no stones were seen on radiography. The urine contained neither tubercle bacilli nor other germs. Blood: hæmoglobin 80 per cent., red corpuscles 4,200,000, leucocytes 4500 (normal formula), platelets 84,000, bleeding-time three minutes. Wassermann reaction negative. The blood-urea was 90 mg. per 100 c.cm. A moderate thrombopenia, combined with arterio-sclerosis, had probably caused this hæmorrhagic condition, and the patient was given 200 mg. redoxon daily. After two days no new hæmorrhages appeared; after four days the urine became much clearer, and after six days the sediment contained no more erythrocytes. For several weeks she took ascorbic acid by mouth (100 mg. daily), and there was no further hæmaturia or other hæmorrhage.

The fifth patient was a man of 62, operated on for lateral inguinal hernia. After operation a large blood effusion was present under the skin, along the right side of the abdomen and the leg and under the skin of the penis. After absorption of this effusion the wound did not cease to bleed, and the surgeon injected calcium, Coagulen, &c., without any perceptible result. When three weeks after the operation the wound was still bleeding I was asked to see the patient. He proved to be a drunkard and had cirrhosis of the liver. This organ was enlarged and firm, and in the urine was a trace of bilirubin. A daily dose of 200 mg. redoxon was given intravenously, and after 48 hours the bleeding had totally ceased.

The five patients of this series had capillary hæmorrhages. Where the hæmorrhage is venous or arterial—e.g., in duodenal ulcer—I should not attempt to treat it with ascorbic acid.

STREPTOCOCCAL INFECTION IN CHILDBIRTH AND SEPTIC ABORTION

SOURCE OF INFECTION AND GROUPING OF HÆMOLYTIC STRAINS

By PHYLLIS M. CONGDON, M.D. Manch., D.P.H.,
Dipl. Bact.

RESEARCH WORKER IN THE DEPARTMENT OF BACTERIOLOGY AND PREVENTIVE MEDICINE, UNIVERSITY OF MANCHESTER

THIS study is based upon 204 cases of puerperal fever and 101 cases of septic abortion. These were bacteriologically examined by taking swabs from the cervix (occasionally from the vagina) whenever possible before any antiseptic treatment had been given. The swabs were cultivated aerobically on blood agar from which strains of hæmolytic streptococci were isolated and shown to produce hæmo-

lysin in Hartley broth cultures. Such strains were obtained from 62 cases of puerperal fever (30 per cent.) and 15 cases of septic abortion (15 per cent.). Of these 77 cases, 33 (43 per cent.) were very severe, endangering life, and 11 were fatal. Only one other death, from puerperal insanity, occurred so that with this exception all the deaths resulted from streptococcal infection.

SOURCE OF INFECTION IN PUERPERAL FEVER

Following the work of Smith (1931) the view became prominent that the source of the majority of puerperal infections due to hæmolytic streptococci is the nose and throat of attendants. It appears however that quite frequently the patient's own nose or throat may furnish a strain identical with that found in the uterus. Hare and Colebrook (1934) noted that about 30–40 per cent. of women who have acute puerperal infection harbour a potentially pathogenic type of streptococcus in the nasopharynx and that often the uterine and nasopharyngeal strains from one patient are serologically identical.

An attempt was made to determine the source of infection in cases that had hæmolytic streptococci in the uterus, excluding septic abortion. Swabs from the patient's throat and nose were cultivated as described above. In respect of 46 cases it was possible to obtain swabs from the throat and nose of attendants and others who had been in contact with the patient. When hæmolytic streptococci were isolated from the nose or throat of the patient, or any of the contacts, the strains were compared with the uterine strain of that patient, to determine whether or not they were identical. If the fermentation tests agreed, sera were prepared and cross-agglutination performed. Agglutinin absorption was used as the final criterion of identity.

In 10 cases hæmolytic streptococci were obtained from one or more contacts, and in 2 of these from the patient's nose or throat as well. In 8 other cases strains from the patient's nose or throat were compared with the uterine strain, contacts not being examined. The results are summarised briefly.

CASE 1.—One strain from the throat of a contact was not identical with the uterine strains.

CASE 2.—Three strains from the throat of three contacts were not identical with the uterine strain, but cultures from the nose and the throat of the patient corresponded with the infecting strain. This patient had laryngitis for a fortnight before confinement.

CASE 3.—A strain corresponding to the infecting strain was obtained from the throat of a contact, but a strain from the patient's throat was different.

CASE 4.—Two strains from the throat of two contacts were not identical with the infecting strain.

CASE 5.—Two strains were obtained from the throat of a contact. One of these and also cultures from the throat and nose of the patient corresponded with the uterine strain.

CASE 6.—Four contacts each yielded hæmolytic streptococci from the throat. One culture was identical with the infecting strain but this came from a nurse who was not attending the patient although employed in the same ward.

CASE 7.—Strains identical with the uterine strain were obtained from the throat and nose of a contact and from the throat and nose of the patient.

CASE 8.—A strain identical with the uterine strain was isolated from the throat of a contact, a handywoman suffering from tonsillitis.

CASE 9.—Two contacts yielded strains from the throat and nose but they were not identical with the infecting strain.

CASE 10.—Occurred in the same ward as Case 9 and had the same contacts. The strains from the throat and nose of one of the contacts were identical with the uterine strain of this case.

OTHER CASES.—In 8 other cases strains from the patient's nose or throat were compared with the uterine strain. In 5 they were identical; in 3 they were different.

Thus for 12 of 18 cases strains identical with the uterine strain were isolated from the throat or nose of the patient herself or of contacts; six times from the patient only, four times from a contact only, and twice from both patient and contact. There is no absolute proof that these were the sources of infection, but it is highly probable. When both patient and contact harbour the infecting strain in the nasopharynx the actual source becomes problematical. In 2 instances pharyngitis or tonsillitis was in evidence.

These results lend support to the view that the source of uterine infection is often the patient's own nasopharynx. And this is further suggested by comparing the incidence of hæmolytic streptococci in the throat and the nose of those who have a streptococcal uterine infection with the incidence among contacts or patients not so infected, as indicated below.

Swabs from the throat and nose were taken from 60 cases of puerperal fever or septic abortion in which hæmolytic streptococci were isolated from the uterus. This organism was obtained from the throat of 12 (20 per cent.) and in the nose of 9 (15 per cent.). These figures contrast with the findings in a group of apparently healthy contacts and patients from whom streptococci were not isolated from the uterus; 341 throat swabs were examined, 38 (11 per cent.) being positive, and of 329 nose swabs only 4 (1·2 per cent.) were positive. The difference is particularly great with regard to the incidence of positive nose swabs.

Of the 60 cases, 16 (27 per cent.) harboured hæmolytic streptococci in the throat, the nose, or in both. As indicated later, cultures from 12 of these cases were shown to belong to the group A of Lancefield (1933), the group that is potentially pathogenic for man and the cause of practically all severe cases of uterine infection in the puerperium.

GROUPING OF STRAINS BY THE PRECIPITIN TEST

Following the technique of Lancefield (1933) and Lancefield and Hare (1935) extracts were made from cultures and sera prepared in rabbits. Four sera containing group precipitin for group A strains and one serum containing group precipitin for group B were used. Some of these sera were tested and their properties confirmed by Dr. Ronald Hare, Queen Charlotte's Maternity Hospital, London, who also tested and assigned to their appropriate group the extracts of our strains that did not react with group A serum.

The importance of group A strains of hæmolytic streptococci in the aetiology of puerperal fever and their potential pathogenic properties for man in contrast to other groups has been stated by Lancefield (1933) and Lancefield and Hare (1935). Our results support this.

(a) *Strains isolated from the cervix or vagina in cases of puerperal fever.*—A total of 61 strains from 57 cases were tested: from the cervix only in 50 cases, from the vagina only in 3 cases, and one strain from each source in 4 cases. Of the 61 strains 60 belonged to group A. The remaining strain belonged to group B. It was isolated from the vagina of a patient who developed septicaemia and

pneumonia and died. A culture from the blood was not available.

(b) *Strains isolated from the cervix in cases of septic abortion.*—One strain from each of 12 cases was tested: 8 were group A, 2 group B, 1 group C, and 1 group D. Two cases were fatal, each infected with a group A strain.

(c) *Strains isolated from the nose or throat of patients with puerperal fever or septic abortion.*—From 12 cases of puerperal fever 17 strains from the patient's nose or throat, in 5 cases from both situations, were tested. These were all group A. In 8 cases they were identical with the culture from the uterus as judged by agglutinin absorption. In 4 cases, although the uterine and nasopharyngeal strains were both group A, they were not identical, presumably belonging to different types of this group. From one fatal case of septic abortion a group A strain was found in the throat as well as in the uterus, but their identity was not tested by agglutination.

(d) *Strains from the nose or throat of contacts with cases of puerperal fever.*—The 17 strains from the throat or nose of 13 contacts were tested: 15 of these were group A, 1 was group B, and 1 belonged to group H.

COMMENTS AND SUMMARY

1. *Streptococcus hæmolyticus* was isolated from the uterus twice as frequently in puerperal fever as in septic abortion, 30 per cent. and 15 per cent. of cases respectively.

2. The importance of group A strains in the causation of uterine infection in the puerperium, as stated by Lancefield and Hare (1935), is again demonstrated. Of 61 strains from 57 cases 60 belonged to group A, and it is not certain that the exception (from the vagina of a fatal case) was actually the infecting strain. In septic abortion group A strains were recovered from the uterus in only 8 of 12 cases.

3. All the deaths, with the possible exception noted in paragraph 2, were caused by group A strains.

4. The statement of Hare and Colebrook (1934) that 30–40 per cent. of women harbour the human pathogenic type of streptococcus in the nasopharynx at the time of puerperal infection and that not infrequently the nasopharyngeal and uterine strains are serologically identical is supported by our results. Hæmolytic streptococci were found in the throat or nose of 16 of 60 cases of puerperal uterine infection (27 per cent.). Cultures from 12 cases only were tested by the precipitin reaction but all were found to belong to group A.

5. An effort was made to determine the source of puerperal uterine infection by looking for a strain of streptococcus identical with the uterine strain in the nasopharynx of the patient or attendants, the criterion of identity being based on agglutinin absorption. In 12 instances identical strains were found, six times in the patient's nose or throat, four times in the nose or throat of an attendant, and twice in both patient and attendant. There is therefore considerable support for the view that the patient's own nasopharynx may frequently be the source of the uterine infection.

This work was initiated by Dr. R. Veitch Clark, medical officer of health for Manchester, and was done on behalf of the maternity and child welfare committee of the public health department of Manchester, who have provided an annual grant for the purpose. The assistance of Dr. D. Sage Sutherland, superintendent of Monsall Fever Hospital, and members of his staff, is also gratefully acknowledged.

EPIDURAL HÆMORRHAGE DUE TO HÆMOPHILIA CAUSING COMPRESSION OF THE SPINAL CORD

By W. M. PRIEST, M.D., M.R.C.P. Lond.

ASSISTANT MEDICAL OFFICER, ST. MARTY ABBOT'S HOSPITAL;
LATE ASSISTANT MEDICAL OFFICER, ARCHWAY HOSPITAL
(LONDON COUNTY COUNCIL)

NEUROLOGICAL complications of hæmophilia, due to spontaneous hæmorrhage into part of the nervous system, are not common. Seddon¹ comments on the rarity of such lesions in reporting a case, probably of hæmatomyelia in the third and fourth lumbar segments causing paralysis of the quadriceps, pectineus and adductor magnus, with sensory loss corresponding to these segments. There were only two neurological complications in 29 cases of hæmophilia quoted by him and observed at St. Bartholomew's Hospital and the University Hospital, Michigan. Only 19 such cases are mentioned in Bulloch and Fildes's monograph on hæmophilia.² Tidy³ states that "the most dangerous hæmorrhages are those into the brain and spinal cord," but no examples are given in this work. A case of hæmatomyelia occurring in the cervical enlargement of a hæmophilic and causing respiratory paralysis is reported by Ordway and Gorham.⁴ Gunther⁵ states that bleeders may have meningeal hæmatomas leading to cerebral or spinal paralysis, but no certain case of the former has yet been known.

Two cases of paraplegia are quoted in Bulloch and Fildes's monograph; one, published by Ledoux in 1876, was that of a boy aged about six, a known hæmophilic, who was suddenly seized with severe girdle pains, and extensive paraplegia set in involving the lower limbs, trunk, and partly the arms. The boy survived this and the case was regarded at the time as one of hæmorrhage into the spinal cord. In the other, published by Van der Scheer in 1850, a man aged 30 was seized with severe pain in the back and paralysis of the legs after his first attempt at coitus; he died comatose and paraplegic the next day.

The clinical features of the case now to be described appear to have been due to a spontaneous epidural hæmorrhage in the upper part of the spinal canal causing compression of the cervical cord. I have found no reported case of this kind, either cranial or spinal, due to hæmophilia. P. E. Weil⁶ records a case of paraplegia caused, he believed, by lumbar puncture carried out four years earlier on a patient who was a hæmophilic. He describes meningeal hæmorrhage as being "altogether exceptional," and stated that this was the only case of the kind that he had seen.

CASE REPORT

A cardboard-box maker, aged 27, was admitted to the Archway Hospital, Highgate, on Jan. 10th, 1934, with a 24 hours' history of acute pain in the neck, legs, and back of sudden onset. When it began, he said, he was unable to bend his back or even to "move at all." He also complained of painful swellings in the left wrist-joint and on the right shin just above the ankle. There was no history of trauma. The previous history was: 1909-10, "rickets and anemia," for which he was treated for some years; 1925, "swelling" over right tibia, and albuminuria; 1926, severe prolonged hæmorrhage following extraction of teeth (transfusion necessary); 1930, hæmatoma of right thigh, which recurred five months later, and hæmorrhage into left knee and right rectus abdominis

muscle. Since 1930 there had been repeated hæmorrhages into the thigh, calf muscles, knee-joint, and left elbow.

No family history of hæmophilia could be obtained even after searching inquiry from the available relatives. That it was absent could not, however, be regarded as established, since the patient's mother was one of a family of fifteen children, and she had lost touch with most of these siblings. The patient had twelve brothers, five of whom died in infancy but there was nothing to suggest hæmophilia as a cause of death. In passing it is worth noting that this case exemplifies the fecundity which has been noted in hæmophilic families.

Examination.—The patient was a frail sallow man of rather poor intelligence. He was fully conscious and showed much anxiety. The temperature, pulse, and respiration-rates were normal. Blood pressure 128/68. No abnormality was found in the heart or lungs; the spleen was not palpable. There was a swelling over the left wrist-joint, with painful limitation of movement, and a tender firm swelling over the crest of the right tibia just above the ankle, about 1½ in. broad and 3 in. long; the overlying skin showed bruising and discoloration. The left foot was almost fixed in plantar flexion with fibrous shortening of the calf muscles which appeared to be adherent to the skin and were presumably the site of an old hæmatoma. Although there were no external signs of bruising anywhere along the vertebral column, there was great pain on flexion and extension of the spine, particularly in the cervical and lumbar regions; but not specially on rotation of the neck. The cervical and upper thoracic spinous processes were very tender. There were no signs of meningeal irritation, such as head retraction or Kernig's sign, and rigidity seemed to be due to voluntary fixation. The patient did not complain of headache but vomited twice soon after admission.

All the tendon-jerks were brisk with the exception of the right ankle-jerk which could not be obtained. The knee-jerks were much increased and there was a poorly sustained left ankle-clonus. Plantar responses were extensor, more markedly on the left. The abdominal reflexes were equal on the two sides. There was no loss of motor power in the legs but the patient was extremely reluctant to move them. There were no sensory changes other than the pain and hyperalgesia already described, and no abnormality in the cranial nerves or fundi. Sphincter control was normal. The urine was loaded with albumin but contained no blood.

On lumbar puncture the cerebro-spinal fluid dripped slowly out and was clear but deep yellow. A report stated that it formed a coagulum overnight, that the total protein was 1.2 per cent., and that there were 4 cells and 9 red cells c.mm. A blood examination showed:—

Red cells	..	6,512,000	Polymorphs	..	75%
White cells	..	7,600	Lymphocytes	..	18%
Hæmoglobin	..	105%	Large mononuclears	..	7%
Colour-index	..	0.8			
Platelets	..	232,000			

The bleeding-time was 1 min. 50 secs., the clotting-time 17 mins., and the capillary resistance normal. The Wassermann reaction was negative.

Course of Illness.—During the week after his admission the patient's general condition improved; no further hæmorrhages were detected, and the pain, controlled by moderate doses of morphia, gradually subsided. It persisted, however, in the lower lumbar region and over the sacrum where it was brought on particularly by flexing the thighs, as in sitting up. A small deep hæmatoma had appeared at the site of the lumbar puncture. Pain in the neck was absent after the first week, but the other physical signs remained unaltered. A mild attack of acute tonsillitis intervened on the sixth day but subsided in four days.

A fortnight after admission there was profuse hæmaturia, with bright red blood in the stools and epistaxis. The patient then complained of much tenderness in the left loin and an examination of the urine revealed the presence of a few hyaline and granular casts, pus cells, and numerous streptococci. There was no increase in pain over the spine, and although the tendon reflexes remained abnormally brisk, extensor responses could no longer be elicited. Radiography of the spine revealed no abnormality.

A further blood count at this stage gave:—

Red cells	..	5,016,000	Polymorphs	..	85%
White cells	..	26,000	Lymphocytes	..	12%
Hb.	..	82%			

Ten days later hæmaturia was still present though it was less severe, and there was still pain in the sacro-iliac region with tenderness in the loin. The patient's general condition was good, and he had no severe degree of anæmia, so that blood transfusion was not considered necessary at this time; the temperature remained normal. A fortnight later the urine contained a trace of albumin and a few red cells. A hæmatoma developed in the left buttock but disappeared in a few days. All pain had gone.

A further blood count gave:—

Red cells	..	5,130,000	Polymorphs	..	69%
White cells	..	7,200	Lymphocytes	..	30%
Hb.	..	90%			

On March 5th, nine weeks after admission, the patient was allowed to get up for the first time, but after three weeks there was a rise of temperature and a large hæmorrhage into the left elbow-joint occurred. (Aspiration with a wide-bored needle withdrew blood clot.) This resolved in ten days. On April 5th the only abnormal sign present on examination of the nervous system was exaggeration of the knee-jerks and left ankle-jerk. Lumbar puncture was repeated and the fluid was quite normal: cells, 5 per c.mm.; total protein, 0.04 per cent.

A further blood count gave:—

Red cells	..	4,960,000	Polymorphs	..	71%
White cells	..	20,400	Lymphocytes	..	29%
Hb.	..	90%			
Platelets	..	659,000			

The bleeding-time was 1½ mins., and the clotting time 30 mins.

The high white count at this stage was presumably due to the process of absorption of blood clot in the elbow-joint.

Early in May the patient was looking and feeling fit and well. He was up and about and free from pain or any other symptoms or signs. The urine contained a trace of albumin and a few red cells but no casts. He was discharged on May 7th and enjoyed good health until December, 1934, when he was readmitted for further hæmorrhages into the elbow and calf muscles. There were no abnormal signs on examination of the nervous system on this occasion. The bleeding-time was 1½ mins. and the clotting time 45 mins. The urine constantly contained a fair trace of albumin, some red blood-cells, and a few hyaline casts. He was discharged fit after a few weeks. The tests for renal function on his first admission to hospital were normal.

DISCUSSION

The case here described is one of acute spinal compression, slight in degree, associated with hæmophilia. There can be no doubt as to the nature of the hæmorrhagic tendency, in spite of the absence of family history and the relatively late onset at 19 years. His history of repeated hæmorrhages into joints and elsewhere since that age, the blood picture, and the clinical manifestations of hæmorrhage were all characteristic.

Although in the illness here described the patient was bleeding from the nose, bowel, kidneys, beneath the periosteum of the tibia, into the left elbow-joint, and, it is assumed, outside the spinal theca—i.e., from no fewer than six situations—he never appeared to be desperately ill. His general condition remained good and gave rise to no great anxiety after the first few days, when the neurological signs began to recede. There was never any severe anæmia, the lowest blood count showing 82 per cent. of hæmoglobin. The advisability of transfusion with a view to increasing the coagulability of the blood was considered during the phase of hæmaturia, but this had almost ceased within a fortnight of its onset, and no transfusion was carried out.

It was noticeable, however, that albuminuria continued, and this had been noted on admission and on two previous occasions, two and nine years previously. There was never any œdema or other signs of impaired renal function, and the blood-urea and urea concentration were normal. Nephritis, a well-known feature in purpura, appears to be a rare complication of hæmophilia, though Barney,⁷ quoting another authority, states that the changes of chronic nephritis are found post mortem in the kidneys of those hæmophiliacs who have suffered from repeated hæmaturia. In addition to the red cells some hyaline and granular casts were present in the urine in this case. The patient apparently had also a mild acute pyelitis, perhaps secondary to the tonsillitis which preceded it, but unequivocal evidence of true glomerulo-nephritis was lacking. I have found no references in the literature to physiological albuminuria associated with hæmophilia except a general statement by Wright and Ross⁸ that it occurs in some conditions, including hæmophilia, where there is diminished coagulability of the blood. It must be remembered that albuminuria had been observed in this patient nine years previously, and although it persisted, there was no evidence of a progressive renal lesion. The exact nature of the renal condition must remain uncertain unless further progress can be observed. It was thought that there might be some relation between persistent albuminuria suggesting undue capillary permeability, and the high protein content of the cerebro-spinal fluid. But in hæmophilia the capillary permeability is unchanged, and the Froin syndrome is more easily explained as purely the result of a spinal subarachnoid block.

When the patient was first seen the association of hæmophilia and severe pain in the back of the neck suggested the possibility of a spontaneous subarachnoid hæmorrhage, but there were no other clinical signs to confirm this and evidence of pressure on the cord was present. Greenfield and Carmichael⁹ state that xanthochromic fluids due to subarachnoid hæmorrhage rarely contain more than 0.100 mg. of protein in 100 c.cm. of cerebro-spinal fluid, even in the most highly coloured fluids. Large amounts of protein, more than 1 per cent., are most commonly associated with cases of spinal tumour, where a well-defined paraplegia usually develops. The signs of cord compression in this patient were slight and transient, but blockage of the spinal subarachnoid space may be complete without severe pressure on the cord itself, and it is assumed in this case that such a block, due to extradural hæmophilic hæmorrhage at the site of pain in the lower cervical region, had occurred. The relatively large amount of protein in the cerebro-spinal fluid suggested that severe obstruction had been present for at least a week or more. The patient, however, declared that the onset of pain dated only from the day before admission to hospital, and it is possible that continual oozing had been going on for some days with extension of the resulting hæmatoma down the cord, where eventually it caused irritation of the lumbar roots. Such a hæmatoma may be expected to extend more easily in a longitudinal direction and signs of direct pressure on the cord may, therefore, be delayed till some time after the onset of hæmorrhage.

That this subarachnoid block was only temporary was shown by the normal pressure and composition of the cerebro-spinal fluid two months later.

My thanks are due to Dr. C. D. S. Agassiz, medical superintendent of Archway Hospital, for permission to publish this case; to Dr. B. Kessel and members of the

staffs of other hospitals in which the patient had been treated, for reports on the previous history; to the staff of the Archway Group Laboratory for the pathological investigations; and to Dr. E. A. Blake Pritchard, consulting neurologist to the L.C.C., for valuable advice in the preparation of this report.

Clinical and Laboratory Notes

PAROXYSMAL TACHYCARDIA TREATED WITH ACETYLCHOLINE

By ARNOLD B. STENHOUSE, M.R.C.S. Eng.

SENIOR HOUSE PHYSICIAN AT THE RADCLIFFE INFIRMARY, OXFORD

ALTHOUGH Stepp and Schliephake¹ in 1925 reported full and almost instantaneous control of recurring tachycardia by intramuscular injections of a 20 per cent. choline derivative solution, and Starr² in 1933 described the immediate termination of 24 attacks of paroxysmal tachycardia in seven patients by the subcutaneous injection of acetylcholine, there are few, if any, accounts of this drug being used for the purpose in this country. The following case suggests that it might be more widely employed.

Acetylcholine is the parasympathetic hormone and is presumed to act on the heart by stimulating the vagal nerve-endings; it has the further action of peripheral vasodilatation, and should therefore be injected only with the patient lying prone, to counteract the accompanying hypotensive effect.

A boy, aged 14, was admitted to the Radcliffe Infirmary on August 13th, 1935. He has two siblings, alive and well; the mother died of "heart trouble." He has always been healthy, except for occasional "bilious attacks." His tonsils were removed 10 years ago and he has worn glasses for 11 years for refraction error. The present illness started on August 8th, five days before admission, with vomiting, and the patient was thought to be having another "bilious attack." He was sent to bed and was seen on August 12th (the day before admission) by his doctor, who noticed that his pulse-rate was unusually rapid. As it did not slow on the following day, and as he was still vomiting, he was sent into hospital.

On admission he was found to be an undersized boy, much cyanosed, and smelling strongly of acetone. He had a dry, thickly furred tongue; the heart, which was not enlarged clinically, was beating with an apparently normal rhythm, at 200-240 per minute, with occasional slowing for a few beats. The temperature was 95.8° F. There was no enlargement or tenderness of the liver, no oedema of the legs or other abnormal physical sign, apart from a few septic teeth. The systolic blood pressure was 80 mm. Hg; the diastolic was not obtainable.

The case was diagnosed as one of paroxysmal tachycardia, and various attempts to control the attack—including

pressure on the carotids, an ice-bag to the precordium, and an intravenous injection of strophanthin gr. 1/500—were made without effect. Quinidine, grs. 2½ was given by mouth four-hourly, but next day, August 14th, the tachycardia was still continuing though after the patient had been put to bed the rate had decreased to, and remained at, 160 per minute. This slight slowing of the heart-rate suggested that the condition might be one of auricular flutter, but an electrocardiogram (Fig. 1) confirmed the original diagnosis of paroxysmal tachycardia, so it was decided to try a subcutaneous injection of acetylcholine (B.D.H.) 25 mg. This was given, with the patient lying prone, but without any obvious result.

On the following day, August 15th, the heart-rate was still 160 per minute, but the heart was enlarging, the apex-beat being just outside the nipple line. The dosage of quinidine was increased to grs. 4 four-hourly, and a further subcutaneous injection of acetylcholine—this time 50 mg.—was given. Two minutes later a few dropped beats were noticed.

On August 16th the apex-beat was in the anterior axillary line, the boy's general condition was good (he stopped vomiting after admission and took fluids well), and the heart-rate was still steady at 160. Another injection of acetylcholine, 75 mg., was given, and two minutes later the heart stopped abruptly for one second, afterwards resuming a normal pace for fifteen seconds; it then alternated a few fast and a few slow beats for one minute and became fast for two minutes. This last sequence was repeated three times in ten minutes. Four hours later there were alternating periods of slow and rapid beating, but the periods of slow rhythm were gradually lengthening. Five hours after the injection the pulse-rate was 72, with an occasional extrasystole, and the volume was good. The apex-beat had returned to within the nipple line.

On August 19th the boy was well. No extrasystoles; pulse slow and steady; blood pressure 85/35; temperature normal; apex-beat in fourth left intercostal space, 3 in. from the midline; no cardiac murmurs audible. Progress was thereafter uneventful until August 22nd, when the apex-beat was again found to be "out"—viz., in the fourth space, 4½ in. from the midline. The heart-rate remained normal (about 60) but an electrocardiogram taken on August 23rd gave evidence of myocardial damage, evidenced chiefly by notching of the QRS wave, and widening of the QS interval (Fig. 2).

Convalescence was uneventful until Sept. 9th, when the boy had five attacks of tachycardia, each of which lasted about five minutes and stopped spontaneously. During the following fortnight he had a few further attacks. He was fully aware of the beginning, duration, and end of each attack, but was never distressed. He had no further trouble in October, and was discharged from hospital, with a good exercise tolerance, on Nov. 3rd. His heart remained enlarged, with slow, steady beat, and no murmurs; his blood pressure was 115/60.

This case presents several unusual features. First,

FIG. 1

FIG. 2

FIG. 1.—Electrocardiogram taken during attack of paroxysmal tachycardia. (The time-intervals are the same as in Fig. 2.)

FIG. 2.—Normal rhythm with notching of QRS wave and widening of QS interval.

the boy's age (14 years) which is young for the onset of paroxysmal tachycardia. Secondly, the large dose of acetylcholine required to control the tachycardia; Starr gives a dose of 30-50 mg. for adults. Thirdly, the absence of any unpleasant sequelæ to the injections, such as a sudden sensation of warmth in the face, hyperpnoea, sweating, salivation, and precordial pain, some or all of which are usually supposed to occur.

As to the cause of the tachycardia, the following are facts of note: (1) there was no previous history of rheumatism; (2) there was no evidence of a diphtheritic infection (throat-swab was negative to Klebs-Löffler bacillus); (3) while in the ward the patient developed a small carbuncle on his right forearm, and *Staphylococcus aureus* was recovered from his throat.

It is difficult to assess the value of any remedy in paroxysmal tachycardia, which is notoriously unresponsive to treatment and usually stops spontaneously; but it seems worth recording that in this case increasing doses of acetylcholine were followed by progressive slowing of the heart-rate. This supports the view that it is valuable in the treatment of paroxysmal tachycardia.

In conclusion, I wish to thank Dr. A. G. Gibson for permission to publish this case, and Dr. W. Stobie and Dr. A. M. Cooke for encouragement and advice in regard to the treatment.

MYELOBLASTIC LEUKÆMIA

PRESENTING SOME UNUSUAL FEATURES

By J. H. WARD, D.S.O., M.C., M.B. Edin.

AND

A. KNYVETT GORDON, M.B. Camb.

MEDICAL SUPERINTENDENT, VIROL PATHOLOGICAL RESEARCH LABORATORIES; CONSULTING PATHOLOGIST TO THE GREAT WESTERN RAILWAY MEDICAL FUND SOCIETY AND TO VICTORIA HOSPITAL, SWINDON

THE CLINICAL ASPECT. (J. H. W.)

Mrs. A., aged 70, had been a patient of mine for 12 years. Except for attacks of bronchitis during the winter she required little medical attention. Towards the end of May, 1935, she complained of weakness.

At first I could find nothing to account for this, but in the first week of June I noticed she was anæmic and this anæmia became more evident. On June 12th I sent a sample of her blood to Dr. Knyvett Gordon for examination and received a report giving a provisional diagnosis of myeloblastic leukaemia with a grave prognosis. At this time she had no other symptoms but weakness. There was no sepsis in the mouth or elsewhere—no enlarged glands, no enlargement of spleen or liver, no hæmorrhage. The urine was free from albumin and sugar.

She was treated with intravenous and intramuscular injections of liver extract daily, with ferri et ammon cit. grs. 30 t.d.s., acid. hydrochlor. dil. m 30 t.d.s., p.c., and injections of calcium gluconate. Clinical response was, however, very slight; her anæmia and weakness continued to increase. On July 3rd the spleen was palpable below the costal border, but the enlargement was temporary for later I could not feel it. She became unconscious on July 13th and died on the 20th.

I made a post-mortem examination on the same day

and found a considerable amount of fat, although no food had been taken for a week before death. The spleen was enlarged to the size of a small coconut and was very friable. The liver was slightly enlarged and very soft. The other organs showed no obvious abnormality. The humerus and portions of the liver and spleen were removed for microscopic examination.

THE PATHOLOGICAL ASPECT. (A. K. G.)

During the illness 22 blood films were examined and five total counts were made on oxalated blood. Subsequently, the liver, spleen, and bone-marrow were scrutinised.

The first set of films, taken on June 12th, showed polynuclears 38 per cent., lymphocytes 10 per cent., hyalines 1 per cent., and eosinophils 1 per cent., with 20 per cent. of myelocytes, 15 per cent. of myeloblasts, and 15 per cent. of myeloblastic plasma cells. The total counts were red cells 3,050,000, white cells 9200, hæmoglobin 51 per cent. A diagnosis of acute myeloblastic leukaemia was made and a fatal prognosis given. The 22 differential counts were then plotted on a graph, which showed a steady relative increase in the number of myeloblasts and corresponding decrease in the polynuclears and myelocytes, the figures for the last test, just before death, being myelocytes 10 per cent., myeloblasts 64 per cent., and plasma cells 3 per cent., with 10 per cent. of a primitive type of cell closely resembling, if not identical with, the lymphoidocyte. The lymphocytes remained steady throughout at about 10 per cent., mononuclears 3 per cent. An interesting feature was the occurrence of transient rises in the relative numbers of the polynuclears, corresponding to the injections of liver extract. The last total count, a week before death, showed red cells 1,475,000, white cells 17,100, and hæmoglobin less than 15 per cent.

Post mortem, the medullary cavity of the humerus was closely packed throughout the length of the bone with marrow of a pinkish-grey. In films and subsequent sections this was found to consist almost entirely of myeloblasts and a more primitive cell resembling the lymphoidocyte. Myelocytes were present, though their granules were scanty suggesting an intermediate form between the myelocyte and the myeloblast. Very few cells of the erythrocyte series were seen. An accurate differential count of the marrow films was scarcely possible on account of the number of dead cells which could not be identified.

The liver showed infiltration, both interlobular and inter-cellular, with myeloblasts; a moderate degree of fatty degeneration was evident and small scattered deposits of free iron were seen. In the spleen, the Malpighian bodies showed no histological abnormality, while the pulp was infiltrated throughout with myeloblasts. Free iron was not found.

The diagnosis of acute myeloblastic leukaemia was clear, the characteristic features in the blood being a steady transition from the granular polynuclear and myelocyte to the non-granular myeloblast and even back to a more primitive cell resembling the lymphoidocyte, together with an "aleukæmic" total count. As usual, the red cell factories became gradually exhausted, which was probably the immediate cause of death.

The last set of films were compared with some prepared from the blood of a lamprey, in which the leucocytes are practically all of the lymphoidocyte group, and the primitive cells of the patient corresponded very closely in type.

The case, presented some unusual features. Firstly, the age of the patient—the disease being uncommon after 25. Secondly, the absence of signs of sepsis in the mouth. This is very uncommon, as in the great majority of cases the illness begins with acute inflammation of the fauces and gums of the sloughing type and is, therefore, not infrequently diagnosed clinically as streptococcal infection, diphtheria, or Vincent's angina, and the condition of the

blood may escape investigation. I have, however, recorded a somewhat similar case¹ in which the age of the patient was 74 and there were no signs of sepsis. The patient died of a terminal pneumonia after a month's illness, with 92 per cent. of myeloblasts in the circulating blood. I have been unable to find any record of other cases occurring in old age.

As a rule, the patients die within a fortnight or so of toxæmia from the septic infection. This is not because sepsis is a cause of leukaemia—though sometimes it has been so described—but because myeloblasts and myelocytes have little or no antibacterial action, whether by phagocytosis or antibody formation. The evidence for this is twofold. If to a healthy subject an injection of sodium cinnamate or nucleinate is administered, the blood shows a marked polynuclear leucocytosis, but in myeloblastic and myeloid leukaemia no such effect is produced. Similarly, in health an injection of T.A.B. vaccine is followed by an increase in the titre of agglutinins to these organisms, whereas in leukaemia no response is evoked.

It is difficult to form any accurate conception of the general incidence of acute myeloblastic leukaemia, because it does not present itself clinically as a disease of the blood-forming organs, but rather as an acute infection. Even if the blood is examined, the absence of a leucocytosis may be misleading. Furthermore, if the slide is overstained or the reagents are not fresh, the nuclear characteristics of the myeloblast may not be evident and the cell is then mistaken for a lymphocyte. In 80 cases of myeloid leukaemia which have come under my personal observation, 6 were found to be of the acute myeloblastic type. The distinction is of clinical importance, because with care and treatment by X rays, *controlled by frequent examinations of the blood*, it is often possible to keep patients of the ordinary myeloid type alive and fairly active for a period of years. In the myeloblastic variety there is no alternative to a rapidly fatal course and treatment can be only symptomatic.

PRIMARY CARCINOMA OF THE LIVER

DESCRIPTION OF AN UNUSUAL CASE

By J. A. MARTINEZ, M.B. Liverp., F.R.C.S. Eng.

LATE SURGICAL REGISTRAR AND TUTOR, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL

SINCE the time when Virchow pointed out the importance of searching carefully for a primary source at autopsy on cases of liver growths, the histology of carcinoma originating in the liver has been well defined, and it is now recognised to be a rare disease. This fact, in addition to the unusual pathology observed, prompts me to publish the following case.

DESCRIPTION OF THE CASE

The patient was a man of 56 who complained of mid-epigastric pain of five months' duration, not associated with food. He suffered also from precordial pain and dyspnoea on exertion. There was no indigestion or flatulence, and he had never been jaundiced. Four days before admission to hospital he had an attack of severe pain in the left loin, mental confusion, and headache, associated with diminution of urinary output and a furred tongue. He had worked in a sulphuric acid works for the previous 18 years, and many years before had been

a heavy drinker, but until recently he had enjoyed good health.

Examination revealed some tenderness in the left loin. The right kidney was unduly palpable, but smooth and mobile and of normal size. No tumour could be felt above it. There was no clinical abnormality of the nervous system. The heart was not abnormal except for the occasional occurrence of multiple extrasystoles. The urea content of the blood was 47 mg. per 100 c.cm. The urine was sterile and acid. It contained 0.5 per cent.

FIG. 1.—The right kidney, whose pelvis is filled with opaque solution, is being displaced downwards by an oval calcified tumour springing from the right lobe of the liver.

of urea, and there were pus cells and granular casts in the deposit. The average daily output was 1650 c.cm.

By cystoscopy a normal bladder and ureteric orifices were seen. The right ureter was catheterised without difficulty and a pyelogram was taken immediately afterwards (Fig. 1). A large oval stippled shadow is seen in the region of the right lobe of the liver displacing the right kidney downwards. It was assumed to be produced by a calcified hydatid cyst of the liver.

Before further investigations could be carried out the patient died quite unexpectedly, seven days after admission to hospital. The mode of death was suggestive of acute cardiorenal failure. The temperature and pulse-rate had not varied from the normal during the period of observation.

Post-mortem examination.—The heart was slightly enlarged, with pale, lax, dilated musculature. There was no coronary or valvular disease, and the aorta was normal. Except for some old adhesions of the left pleura, the lungs were normal. There was no ascites, and no abnormality of the gastro-intestinal tract, spleen, or pancreas. The liver was adherent to the diaphragm. An ovoid smooth tumour, size 14 × 9 × 7 cm., sprang from the under surface of the right lobe, pushing the liver upwards, the kidney downwards, and the inferior vena cava to the left. It was adherent only to the liver and diaphragm, and was easily separable from the other adjacent viscera. It was completely enclosed in a thin, irregularly calcified shell. On section there was a central branching core of gelatinous fibrous tissue surrounded by a homogeneous, soft, friable, vascular substance, maroon in colour. At no point was continuity demonstrable between this tumour substance and the surrounding liver; it was everywhere separated from it by the capsule. The rest of the liver was quite normal, and did not show any of the macroscopic changes of cirrhosis or new growth. No other abnormality was found except for a few patches of cortical

¹ Med. Press and Circ., 1931, cxxxi., 207.

necrosis in the left kidney over which the surrounding capsule was adherent.

Microscopical sections stained with hæmatoxylin and eosin show the tumour to consist of a degenerated oedematous fibrous core and epithelial cells growing in strands and small masses. The cells are irregular in size and shape, but mainly polyhedral, and resemble the cells of the liver parenchyma. Most of them have a circular eccentric nucleus with a well-marked chromatin network and nucleolus. Some have two or more nuclei, and giant cells of four or five nuclei are common. The cytoplasm is pale, uniform, and basophil. Much extravasated blood

FIG. 2.—Section of the growth ($\times 300$). Multi-nucleated giant-cells are seen, and much extravasated blood in the intervening spaces.

fills the spaces between the tumour cells (Fig. 2). Sections taken from various parts of the liver do not show any of the changes of cirrhosis.

DISCUSSION

Classification of primary carcinoma of the liver.—The following classification is suggested by Ewing:

- (1) Hepatoma, arising from the cells of the liver parenchyma.
- (2) Cholangiona, arising from the intrahepatic bile-ducts.
- (3) Mixed type, containing elements of both.

Each of these types may occur as a solitary adenomatous or carcinomatous tumour, as a massive infiltrating growth, or as multiple nodules. Cirrhosis coexists in 85 per cent. of hepatomas and 50 per cent. of cholangionomas (Eggel). It is uncertain which of the two main types is commoner, but more cases of the hepatoma group have been reported.

Clinical features.—There is no characteristic clinical picture. Wasting, anemia, and pain in the epigastrium or right hypochondrium with ascites may indicate the presence of a malignant tumour. Jaundice is present in 61 per cent. of cases, and is commoner in cholangionomas than in hepatomas. The spleen is enlarged in a third of the cases. Fever and leucocytosis are found in 14 per cent., and are associated with rapidly growing necrotic growths.

Four well-defined clinical types can be distinguished:

- (1) No symptoms are referable to the growth, and the patient dies after a short illness, as in the case here described.
- (2) Carcinoma of the liver is found at autopsy on patients dying from other conditions.
- (3) A well-marked history of cirrhosis ends rapidly with hepatic tumour, wasting, jaundice, and ascites.
- (4) An obviously malignant enlargement of the liver develops in a previously healthy patient. These are

usually mistaken for the much commoner cases of extensive secondary deposits in the liver without an apparent primary growth.

Nature of primary liver growths.—The sequence of cirrhosis, regenerative nodular hyperplasia, multiple adenomata, and carcinoma is a well-recognised fact, and serves to explain the origin of those cases in which carcinoma is found in association with cirrhosis. In districts where parasitic diseases such as distomiasis and schistosomiasis are common causes of liver damage, primary carcinoma is relatively frequent. Thus L. W. Smith states that the ante-mortem diagnosis is readily made in the Philippine Islands, while Strong and Pitts point out that the disease is unusually prevalent amongst Chinese patients at the Vancouver General Hospital.

There occur cases, however, in which cirrhosis seems to be a secondary process resulting from the mechanical stimulus of the tumour itself, while it is absent in some 15 per cent. of liver-cell and 50 per cent. of bile-cell growths. For these a different mode of origin must exist. It is likely that many carcinomas not associated with cirrhosis result from the malignant transformation of a solitary adenoma, the process taking many years to evolve. Pepere goes so far as to state that all solitary adenomas of the liver are congenital, while congenital malignant adenomas have been recorded by Ribbert, Prescott, Karsner, Milne, and others. In the tumour here described, the presence of a complete calcified capsule is indicative of many years' duration, yet the microscopical appearance was one of active malignancy, and it is likely that the growth originated in a congenital adenoma which eventually underwent malignant transformation.

It is rare for primary liver carcinomas to metastasise, and extrahepatic metastases are found in only 20 per cent. of cases. The method of spread is by vascular embolism, the liver, lungs, and regional lymph glands being most commonly invaded. Distant metastases of hepatoma have the property of secreting bile and thus present an interesting analogy with metastases of thyroid carcinoma.

SUMMARY

A case is described of primary carcinoma of the liver presumably originating in a congenital adenoma. The clinical features and pathological nature of these rare growths are discussed.

I am indebted to Mr. Philip Hawe, of the David Lewis Northern Hospital, Liverpool, for permission to publish notes of this case.

QUEEN MARY'S HOSPITAL, FOR THE EAST END.—The Duchess of Marlborough presided at the festival dinner in aid of this hospital held at the Hotel Victoria on Nov. 23th. The institution serves a population of nearly 2,000,000 and requires an annual income of £50,000. A sum of £25,000 is required to clear off arrears and another £15,000 to build operating theatres, which are urgently needed. Subscriptions amounting to over £7000 were announced at the dinner.

MEDICAL SOCIETIES

TUBERCULOSIS ASSOCIATION

At a meeting of this association held at Manson House on Nov. 22nd, papers were read by Dr. E. L. MIDDLETON (H.M. Medical Inspector of Factories) and Dr. P. HEFFERNAN on

Industrialism and Tuberculosis

Dr. Middleton said that, after spending nearly fifteen years in matters relating to industrial hygiene, he had been impressed by the importance of the effect of certain occupations on the health of those taking part in them, and he wished particularly to emphasise the necessity for medical men to have some knowledge of the occupations in which their patients had been engaged. The occupational history might be quite as important as any other part of the past history of the patient. In certain scheduled industries, selection of individuals was carried out by statutory medical examinations of persons within two months of their employment. In these industries, which included occupations in which the workers were exposed to silica and asbestos dusts, the law provided for periodical medical examinations, at which the worker would be suspended if he was found to be suffering from tuberculosis or from pure silicosis to such a degree as to make it dangerous for him to continue work in that industry. There was a definite relationship between the occupational risk and the health of the individual. The two important factors in the spread of disease were, the opportunities for infection and the susceptibility of the individual to infection. Occupation might have a bearing on each of these factors, both in a general and in a special sense: in a general sense through proximity, the presence of infected dust, or defective work-room conditions which lowered the vitality and diminished the resistance of the workers; and in a special sense, among those whose occupation rendered them more liable to suffer from tuberculosis, as, for example, in a metal-grinding factory in which grindstones were used. Here not only would the chances of infection be greater than among the general population, but also the workers had been rendered specially susceptible to tuberculosis because they had inhaled siliceous dust and were, in fact, subjects of silicosis, whether in a diagnosable stage or not.

The real hazard to which workers in the silica group of occupations were exposed was silicosis and, strictly speaking, not tuberculosis. The association of the two conditions had been held to be so close that tuberculosis was taken as an index of the incidence of silicosis in certain industries. There were, however, all shades of opinion on this relationship. In a recent article, E. L. Collis and G. Udny Yule (*Jour. of Indust. Hyg.*, 1933, xv., 395) had presented the mortality experience of an occupational group exposed to silica dust, as compared with that of a group exposed to dust not containing silica, and with that of the standard population of England and Wales. This study threw into sharp contrast the unfavourable position of persons employed in six selected groups of occupations exposing them to silica dust compared with workers in five selected occupational groups who were exposed to non-siliceous dusts. The excess mortality in the former class, though not confined to diseases of the respiratory system, was particularly notable in the figures for respiratory tuberculosis.

Dr. Middleton then threw on the screen slides illustrating the various processes in certain industries. In the *pottery industry* the occurrence of silicosis was especially associated with two sub-groups: earthenware and china. The *sandstone industry*, which included the quarrying and dressing of sandstone, represented perhaps the most widespread of all the silicosis-producing industries. Dust was produced in all processes in which the stone was cut, and in some of these processes the concentration of the dust cloud reached high limits. In the *granite industry*, in which the processes corresponded with those in the sandstone industry, the incidence of silicosis was not so severe. In both these industries silicosis was most frequent among the masons. The reason for the less severe involvement of the lungs in granite workers as compared with sandstone workers might be related to the composition of the dust. In granite, the amount of free silica rarely exceeded one-third of its weight, the other constituents being silicates, in which silica was present in chemical combination. *Grinder's rot*, the name formerly given to silicosis occurring in metal-grinders on sandstone, was a type frequently associated with tuberculosis. Grindstones made of sandstone had, however, been largely replaced by grinding wheels of artificial abrasive, such as carborundum and alumina, which contained almost no silica. *Sand-blasting* was at present the most serious cause of silicosis. The occupation was confined to a comparatively small number of workers, but had a high rate of mortality, and the onset of the disease followed a shorter period of exposure than occurred in almost any other of the silicosis-producing industries. *Manufacture of scouring powders*. This was a small industry, and from the point of view of silicosis it was not now important owing to the measures which had been taken to control dust produced in the processes. *Coal-mining*. The occurrence of silicosis was now well recognised amongst coal-miners, especially in the South Wales coalfield and in Europe and America. In the 3½ years ended December, 1934, the Silicosis Medical Board issued 702 certificates on account of silicosis in coal-miners, and, of these, 602 were in the South Wales area.

SILICOSIS AND DUST RETENTION

Dr. HEFFERNAN said that the main problem in industrial tuberculosis was the silicosis problem. It appeared to him that most of the prevailing confusion, controversy, and difference of opinion regarding pneumoconiosis and its relation to tuberculosis could be traced to a confusion between two entirely different conditions—silicosis and dust retention. Silicosis was an active and dynamic process with a specific histopathology, produced by the inhalation of free silica, or possibly its chemical equivalent, in a very fine state of subdivision. It was usually said that the dust particles must be below 2 microns in diameter to affect healthy lungs; below that limit, the smaller the dust particles, down to submolecular dimensions, the more active and rapid the development of the condition. Dust retention, on the other hand, was a passive process occurring typically in diseased lungs. Healthy lungs were capable of dealing with all forms of dust except that of free silica, or possibly certain combinations of silica-like asbestos, which when powdered might be capable of acting chemically as free silica did. The fibrosis produced by silica dust was characteristically nodular, was situated mainly subpleurally in the little collars of lymphoid tissue surrounding the necks of the infundibuli, gross obstruction of the root lymphatics and hilum glands being slight or absent. The fibrosis associated with dust retention was not nodular, was situated mainly at the roots of the lungs, and tended to spread outwards. The hilum lymphatic glands were affected and were greatly enlarged and packed with dust, general

thickening of the mediastinal mass following. In typical simple silicosis there were few pulmonary symptoms, apart from advancing dyspnoea and some cyanosis. In dust retention, in addition to the symptoms of pulmonary fibrosis, there was the presence of symptoms of the antecedent pulmonary disease—emphysema, chronic bronchitis, bronchiectasis, pulmonary tuberculosis. Finally, silicosis definitely predisposed to the development of pulmonary tuberculosis late in life, which dust retention per se did not do.

Although, however, these two conditions were entirely different, yet the problem was complicated by the fact that all lungs subject to silica dust were not healthy, and the reaction to silica of an unhealthy lung could be very different from that of a healthy lung. The specific fibrosis now tended to be massive in the diseased areas while still remaining discrete and nodular in the healthy areas, and the phenomena of dust retention were added to those of silicosis. They had therefore at one end of the scale, simple silicosis, with its liability to tuberculosis; at the other end simple dust retention with no such liability; and in between, various intermediate conditions, determined mainly by the two variables—the condition of the lung previous to and during exposure, and the proportion of free silica in the dust, with the size of its particles and possibly its freshness. The prevention of simple silicosis in healthy workmen obviously lay in the elimination of the dust of free silica in the atmosphere in which they worked, and in this direction great progress had been made; while to prevent the employment in dusty industries, such as coal-mines, of men with lungs already diseased, a careful "hand-picking" of the men at entry would be necessary, with periodic medical re-examination and elimination of all persons suffering from any form of pulmonary affection.

These conclusions, said Dr. Heffernan, were based upon 17 years' service as tuberculosis officer in Derbyshire, with a fairly extensive study of the literature. There were over 40,000 coal-miners in Derbyshire, and over 2000 limestone workers. They had never had a single case of silicosis reported in a coal-miner or a limestone worker, and their tuberculosis death-rate was normal or below normal. On the other hand, they had a few hundred gritstone masons and stone-cutters. Twenty-five years ago the death-rate from pulmonary tuberculosis among these men was more than ten times that amongst the adult general population of Derbyshire; and for the decade ending 1921 it was still five times the adult pulmonary tuberculosis death-rate. He was convinced that the freedom of coal-miners from terminal pulmonary tuberculosis was not, as had been suggested, because coal dust neutralised or minimised the toxins of the tubercle bacillus. The real reason was that, save in the mines where the men had to drill seams of quartzose rock, they did not suffer from true silicosis at all.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

THE November meeting of this society was held at Sheffield.

Unilateral Menstrual Pain

Prof. MILES PHILLIPS said that this term, although somewhat clumsy, was the best he could devise for a certain clinical group of cases in which severe pelvi-abdominal pain occurred solely in association

with the menstrual periods, only and always on one and the same side. Two principal conditions were liable to cause such pain—namely, localised cornual adenomyoma, and hæmatometra in the rudimentary horn of a double uterus. Careful and understanding analysis of the patient's symptoms lead one to make a provisional diagnosis sufficiently correct to justify an exploratory operation. Prof. Phillips described in detail a number of cases in which the main symptom was fairly severe pain just at the onset of menstruation, in which, at laparotomy, typical adenomyomata were found in the uterus and excised with complete relief of the symptoms. Hæmatometra in the atretic horn of a double uterus was, he said, commonest on the right side, leading to a confusion with appendicitis and removal of this organ, with subsequent persistence of the symptoms which were alleviated only by removal of the rudimentary horn later.

Dr. J. W. BRIDE (Manchester) referred to a case of a calcified foetus with a rudimentary horn, in which the patient's main symptom was dysmenorrhœa.—Dr. K. V. BAILEY (Manchester) asked whether endometrioma of one ovary could possibly cause unilateral dysmenorrhœa.—Prof. LEYLAND ROBINSON (Liverpool) said he thought the characteristic thing about these cases was that there was no variation in the menstrual pain, except perhaps that it got progressively worse.—Prof. DOUGAL, Mr. STACEY, and Mr. GLYN DAVIES mentioned that they had also come across cases of dysmenorrhœa with causes similar to those Prof. Phillips had described.

Chorio-Angio-Fibroma

Dr. C. H. WALSH (Liverpool) described a case of chorio-angio-fibroma, and said that the solid tumours of the placenta were extremely rare. They were of interest pathologically, and clinically they might be associated with abnormal states of the pregnancy and difficulties in the labour.

The specimen was obtained from a patient after delivery of her second child. The tumour of the placenta could be felt in the early stages of the labour through the external os. The labour was normal and the puerperium uneventful. The placenta with its two tumours weighed 2½ lb. One tumour was the size of a grape-fruit and the other the size and shape of a cricket ball. They were embedded in placental tissue and there was a definite pseudo-capsule. The placental tissue was not infiltrating the tumours which could be shelled out easily. The cut surface was solid and looked like a soft fibroid. Microscopically they were found to consist of fibrous tissue with oval cells. In parts there were numerous blood-filled capillaries. The tumours appeared to be angio-fibromyomatous.

Advanced Ectopic Pregnancy

Three cases of advanced ectopic pregnancy were described.

(1) Mr. N. L. EDWARDS (Derby) described a case of a 5-para, aged 42, who passed per rectum portions of the foetus, which was subsequently found to be lying in an extra-uterine sac.

(2) Mr. GLYN DAVIES stated that his patient, who was 26, was a 2-gravida. Her last menstrual period had occurred 23 weeks before, and she had had several shows. Radiography suggested death of the foetus which was presenting by the breech. As the pregnancy was thought to be intra-uterine, an attempt was made to induce the patient but failed. Subsequent examination under anaesthesia led to the diagnosis of ectopic gestation. At operation it was found to be a right-sided ovarian pregnancy, advanced to about the thirtieth week.

(3) Prof. A. M. CLAYE (Leeds) said that his patient was a primigravida, aged 25, who was complaining of abdominal pain for the last three months. There had been some hæmorrhage on several occasions preceded by six months' amenorrhœa. The patient could feel fetal movements.

When seen in September, 1934, the case was diagnosed as one of missed abortion. Attempts were made to induce labour. Subsequent examination under anaesthesia, and radiograms, led to a diagnosis of ectopic gestation. At operation the amniotic sac was found amongst the intestines from which the macerated fetus was removed. The placental site was in the neighbourhood of the left Fallopian tube and the placenta and most of the sac were removed. Haemorrhage was not excessive. Convalescence was uninterrupted. The points of interest in this case were: (1) the diagnosis (which was not reached for a very long time), and (2) the treatment at operation.

The PRESIDENT said that in cases where the condition was not diagnosed until some time after viability he wondered whether the operation could be delayed in order to obtain a live child.—Dr. BRIDE said that in his experience the condition was difficult to diagnose. He thought it safer to leave the placenta in situ when operating on these cases.—Prof. PHILLIPS said that he had seen six cases of advanced ectopic pregnancy. On three occasions he had left the placenta behind and had no trouble subsequently.—Mr. J. ST. GEORGE WILSON (Liverpool) mentioned a case which he first saw half-way through the pregnancy. He opened the abdomen at term and found the fetus in the broad ligament. He was able to deliver the baby alive and left the placenta in the abdomen. Later he had occasion to reopen the abdomen and found no sign of the placenta.—Prof. D. DOUGAL (Manchester) referred to a case in which bougies were introduced and passed through the fundus of the uterus. An abdominal operation had to be performed and the sac containing the placenta, together with the uterus, was removed.

Dr. BRIDE showed a stone, weighing 4 oz., removed from the bladder by suprapubic cystotomy. Its presence was first noticed when a radiogram was taken during the last weeks of pregnancy. Caesarean section was carried out.

LIVERPOOL MEDICAL INSTITUTION

At a meeting of this institution on Nov. 14th, with Dr. C. O. STALLERASS, the president, in the chair, a lecture-demonstration on

Cineradiography

was given by Dr. RUSSELL REYNOLDS (London), who described his method of obtaining cinematographic records of X ray pictures by photographing the screen image. A 16 mm. cinematograph camera is used, and it is only necessary to take a short length of film of any one subject. The short film can then be formed into a band and run through the projector continuously so that the cases may be studied at leisure. Thus the expense of operating the apparatus is reduced to a minimum. Exposures of various parts of the human body have been made; and Dr. Reynolds stated that the joints, movements of the heart and thorax, the act of swallowing, and the passage of an opaque meal through the oesophagus, stomach, and duodenum had all been demonstrated satisfactorily. He thought that the method had many possibilities in diagnosis and for the study of physiological problems.

In the discussion which followed, Dr. R. E. ROBERTS spoke of the high quality of the radiograms obtained. Far from there being any graining or blurring, such as one would expect from photography of a screen image, many of the pictures were as clear as if they had been made under the most favourable conditions of direct radiography. In Dr. Roberts's opinion,

the method would find its greatest usefulness in examination of the thoracic contents. Much new information should be obtainable, for example, about the movements of the heart.

Malignant Effusions

At a pathological meeting on Nov. 21st, with the president in the chair, Dr. R. Y. DAWBARN read a paper entitled *Some Observations on Malignant Effusions*. The examination of peritoneal fluid or pleural fluid for cancer cells need not be abandoned, he said, as a hopeless task. It was certainly almost impossible to recognise these cells in stained dry films, because the endothelial cells were too confusing; but many good results might be obtained by the comparatively old method of cutting paraffin sections of the centrifuged deposit.

After centrifuging the fluid in a large tube (about 1 in. in diameter with a round bottom) the supernatant fluid is poured off and the deposit washed in saline. The centrifuging is repeated if necessary. The saline is then replaced by Zenker's fluid and the deposit carefully separated from the bottom of the tube, without breaking, by means of a platinum wire. The deposit is left in the fixative over-night, after which it is treated with iodine in 50 per cent. alcohol, dehydrated, and embedded in paraffin. Sections are cut and may be stained with Weigert's iron hæmatoxylin.

Tumour cells might be recognised by various criteria: (1) they might be found in clumps, reproducing gland acini or the solid alveoli of carcinoma; (2) mitotic figures were an important, though not infallible, sign of tumour cells; (3) they often had hyperchromatic nuclei and might be far larger than any endothelial cells; (4) karyorrhexis was common in tumour cells, but rare in endothelial cells; (5) vacuoles occurred both in endothelial cells and tumour cells, but in the latter they might be very large and irregular in shape. Dr. Dawbarn showed sections illustrating the above points, including one made from the ascitic fluid of a case of Hodgkin's disease, in which a mitotic figure could be seen, apparently in an endothelial cell—a finding which must, he said, be very unusual.

WOLVERHAMPTON AND DISTRICT CLINICAL CLUB

At the first meeting of the winter session, with Dr. S. C. DYKE in the chair, a discussion on Diseases of the Thyroid Gland was opened by Dr. J. H. SHELDON. The commonest exciting cause of exophthalmic goitre was, he thought, mental shock, the next in order being chronic septic infection—e.g., from the tonsils. The correct treatment of the disease was at present surgical, but there was some indication that pituitary disorder was at the back of exophthalmic goitre, and that ultimately the treatment might be medical by means of an antihormone. Ergotamine tartrate was of use in intractable cases.—Mr. R. MILNES WALKER believed that septic foci should be eradicated before operation, except in very acute cases. The chief indication for early surgical interference was rapid loss of weight. Preoperative treatment with iodine was essential, and Avertin was of great service in anaesthesia.—Dr. C. M. RIGBY, speaking of X ray treatment, said that the early cases were the most successful. Preliminary iodine medication, discontinued during treatment, was as essential as before operation.—Dr. W. R. SOMERSET mentioned cases which had improved after tonsillectomy.

REVIEWS AND NOTICES OF BOOKS

Hæmochromatosis

By J. H. SHELTON. M.D. Lond., F.R.C.P. Lond., Hon. Physician to the Royal Hospital, Wolverhampton, and the Guest Hospital, Dudley; late Hunterian Professor, Royal College of Surgeons of England. London: Humphrey Milford, Oxford University Press. 1935. Pp. 382. 25s.

THE monograph on hæmochromatosis by J. H. Sheldon will surely become recognised as the classical account of this mysterious disease. Dr. Sheldon says in his preface, and none will disagree, that without adequate case records it is impossible to construct a faithful description of any diseased state. He has collected 311 such records, which he accepts as genuine, from the literature, and has analysed them in order to present as complete a picture as possible of the clinical features and pathological appearances characteristic of hæmochromatosis. He discusses also the knowledge available concerning the metabolism and chemical findings, and the experimental work that has been done in an attempt to produce a similar picture in animals. Finally, he allows himself the pleasure, as he says, of "coming off the fence" in a discussion of the pathogenesis of hæmochromatosis. He concludes that it should be classed as an inborn error of metabolism affecting the inner metabolism of probably all the cells of the body (with the possible exception of nervous tissues), which shows itself by a disturbance of the metabolism of melanin and by the formation of iron containing pigment in nearly all the tissues. Neither of these pigments is peculiar to hæmochromatosis, and though the disturbance of metabolism is congenital in origin, he considers it does not produce of itself any disturbance of health, beyond initiating a process of cirrhosis in many organs and leading in time to accumulation of pigments, which ultimately give rise to the well-known triad of symptoms. In spite of the comparative rarity of hæmochromatosis, this scholarly study should interest workers in many fields, since the disturbance in iron metabolism appears to be accompanied by other profound changes in certain of the inorganic constituents of the body, notably copper, calcium, sulphur, sodium, and possibly magnesium.

The book is most carefully documented throughout, and completed with a bibliography of nearly 600 references. It can be recommended both to research workers and clinicians as a clear account of the present knowledge of a rare but key disease, an understanding of which should throw light on many aspects of the fundamental problems of cell metabolism.

A Textbook of Physiology

Fifth edition. By WILLIAM D. ZOETHOUT, Ph.D., Professor of Physiology in the Chicago College of Dental Surgery (Loyola University). London: Henry Kimpton. 1935. Pp. 694. 18s.

TEXT-books of physiology are usually dominated by the position of physiology in the medical curriculum, a previous knowledge of elementary biology, physics, and chemistry being taken for granted. Only in some of the larger "complete" text-books and the small popular works is the subject treated *ab initio*. The present volume furnishes an exception to this rule, for it is of medium size and yet quite general in its scope, and while it would be incorrect to say that no

previous knowledge is required to read it, it is evident that considerable trouble has been taken to explain clearly that part of the subject known as "general physiology," and to provide introductory chapters on general biology and histology. This naturally detracts from the scope of the sections on the several systems of the body, particularly as they often need a short introduction, but these are well balanced in relation to each other and to the rest of the book, and sufficient references are given to monographs and reviews to put the student in a position to enlarge his knowledge.

Nowadays a considerable and growing interest in physiology is being manifested by many groups of students who have other objects than the practice of medicine as their aim, and to them this book may be recommended as a clear and comprehensive exposition of the subject, sufficiently detailed for ordinary purposes. Practical applications to everyday life, as in the sphere of nutrition, are indicated, and there are useful glossaries of technical terms, prefixes, and suffixes for those who might find the text difficult. It should be emphasised however that the book is not a "popular" work, but is intended for serious study by those "having a limited length of time for the acquisition of a basic knowledge of the subject," and is suitable for examination work. The text is generously illustrated, and in the main the figures are well chosen, the only criticism being that there are photographs and drawings of apparatus with which the student should be brought into personal contact, and which might therefore be considered redundant. The spelling, and in many places the terminology, is American.

The main features of the book may be summarised by saying that it is straightforward, of reasonable and convenient size, and complete in itself, neither introductory nor auxiliary—of the biochemical or special sense—texts being essential to supplement it.

Recent Advances in Laryngology and Otology

By R. SCOTT STEVENSON, M.D., Ch.B., F.R.C.S. Edin., Surgeon, Metropolitan Ear, Nose, and Throat Hospital; late First Assistant, Ear, Nose, and Throat Department, University College Hospital. London: J. and A. Churchill Ltd. 1935. Pp. 346. 15s.

Mr. Scott Stevenson says he has spent over five years in the preparation of this book; the outcome of his toil is a well-presented summary of modern work in oto-laryngology. Little has been included which could be called unworthy of classification as a "recent advance," though a more berterial attitude would have been welcomed in places. At the end of each chapter is a paragraph of conclusions, but too often this is merely a summary of the preceding matter. The chapters on X ray and radium treatment of malignant growths are good. The broad general principles are well considered, and enough detail is given to illustrate the points. Those wanting to master the subject will find it necessary to study the original papers, as results are largely governed by attention to detail; it is therefore satisfactory that the references given are numerous and well chosen. In connexion with the radiological examination of the nasal accessory sinuses German workers have received less than their due recognition, but the work of the Americans is fully reported,

including Proetz's method. The author hardly lays sufficient stress on difficulties of interpretation; experienced workers find that X ray pictures must be considered in relation to operative and post-mortem findings if the fullest information is to be extracted from their study. The description of Ferris Smith's external ethmo-fronto-sphenoidal operation is too elaborate for a procedure whose rationale is far from established. On the other hand, the Proetz method of displacement treatment is too briefly dismissed. A warning in this chapter concerning unskilled nasal operation due to lack of training might have been amplified in general terms to cover the whole specialty. In this connexion some consideration of the organisation of research and teaching units in this country compared with those abroad would be valuable in a future edition.

Mr. Scott Stevenson has performed with some address the difficult task in reviewing the recent work on the physiology of hearing and the function of the labyrinth. The results reported in these fields are confusing, and it is a help to find the separate contributions of many research workers so ably sifted. The Wever and Bray phenomenon is clearly discussed, and the work in progress at Harvard and Johns Hopkins following upon this discovery is noted. McNally's experiments on utricular function are briefly described with his conclusion that the utricle acts in opposition to the contralateral vertical semicircular canals. The Ballance-Duel nerve-grafting method in the treatment of facial palsy has a useful chapter to itself.

Very few omissions of any importance can be detected. Some misprints will doubtless be corrected in future editions. The index is good and the book as a whole a most creditable production.

A Briefer General Psychology

By GARDNER MURPHY, Columbia University.
New York and London: Harper and Brothers.
1935. Pp. 572. 10s. 6d.

THIS book shows admirably the links between physiology and psychology. It is clearly written, and the subject is developed in the simplest possible way. Those who have studied physiology will find many experiments described with which they have already become familiar, and will be interested in their interpretation from a new angle. Indeed, one would recommend the book with less reservation to medical students than to other readers, for not only will it harmonise with their other preclinical studies, but they will be in a better position to read it critically. The author claims, quite fairly, that he has presented only such material as furnishes common ground for the beliefs held by the majority of psychologists, but some physiological theories are taken too readily and accepted as facts on which to base certain conclusions. Nevertheless, no unreasonable interpretations are made, experimental evidence is introduced wherever possible, and this is not bent to the support of any particular "school." The aim of presenting only general principles is well maintained, but the scope of the various specialised branches of the subject—child psychology, social psychology, &c.—is indicated.

An unusual amount of trouble has been taken to help the serious student. The subheading of each section is given in the table of contents, illustrations are numerous and have exceptionally full legends, while references to other works and a summary are provided at the end of each chapter. The only

feature unlikely to appeal to the English reader is the list of questions also appended to each chapter, an aid to learning usually found in less authoritative works and not in the tradition of university education in this country. The index is also a glossary, and is preceded by an extensive list of references to literature each relating to a statement in the text whose page, paragraph, and line is specified. The student is, therefore, not only encouraged to learn thoroughly, but also to investigate for himself. These features, together with the sane and interesting way in which the book is written, should carry it not only to the shelves of avowed students of psychology, but also to those of others who feel that an elementary knowledge of the subject is essential.

High Blood Pressure and its Common Sequelæ

By HUGH O. GUNWARDENE, M.B., B.S. Lond.,
D.M.R.E. Cantab., Clinical Assistant, National
Hospital for Diseases of the Heart, London,
1917-24. London: Baillière, Tindall and Cox.
1935. Pp. 172. 7s. 6d.

THIS is a good and clinically useful little book. The author rightly insists that it is the height of the diastolic rather than of the systolic pressure which is the true index of hypertension, the former being notoriously more stable than the latter. He regards a persistent diastolic pressure of 90 mm. Hg as the lower limit of abnormality and considers that if it rises to 115 it never returns to normal. He makes much of the hypertensive factor as a cause of heart disease and quotes the astonishing figures of Major and Fahr to the effect that there are 10 million persons with high blood pressure in America. Dr. Gunewardene states that when the diastolic pressure reaches 135 mm. Hg prognosis will have to be based on a general examination of the patient, but surely this is true of all cases of hypertension? The importance of differentiating renal from non-renal hypertension is emphasised and an excellent differential diagnosis table is supplied on p. 69. Like others, the author finds non-renal hypertension rare in those under 30 years old. In common with most pathologists and many clinicians, he disapproves of the term "malignant hypertension." Without going too deeply into aetiology, he believes that overfeeding and sedentary habits may be a causative factor in high blood pressure and makes out a good case for this hypothesis. Chapter V. contains an interesting piece of clinical observation on the influence of occupation and manner of living on the height of the blood pressure. In the author's experience, occupations involving more than ordinary physical exercise tend to produce blood pressures lower than normal. All would agree that prognosis is bad when retinal hæmorrhages and exudate are present, but the fact that solitary hæmorrhages which clear up may occur in cases of simple hypertension is not mentioned. Dr. Gunewardene has not seen strokes occur in patients with diastolic pressures of less than 115 mm. Hg. This is an observation deserving further inquiry. Chapter XV. contains a study of acute œdema of lungs which, apart from acute infections, is believed to be due often to persistent hypertension. In the chapter on prognosis he says that when cardiac failure or enlargement are present, strokes are less likely to occur—a statement difficult to prove. He believes that all cases of hypertension require treatment or, at least, medical supervision, and that when the blood pressure is raised attempts to reduce

it by natural means such as regulated exercise, dietetic restriction, and curtailment of business cares, should always be made. He thinks that the blood pressure can sometimes be lowered by the removal of septic foci and quotes O'Connor on prostatectomy as a means of lowering blood pressure raised as a result of renal damage in cases of prostatic enlargement. Dr. Gunewardene believes in the use of vasodilator drugs; when he condemns rigid systems of dieting he is, perhaps, on less controversial ground. On p. 73 the word "starving" is used when "fasting" is obviously intended. There is an adequate index but no bibliography.

A Textbook of Clinical Neurology

Third edition. By ISRAEL S. WECHSLER, M.D., Professor of Clinical Neurology, Columbia University, New York; Attending Neurologist, Neurological Institute and Montefiore Hospital. London: W. B. Saunders Co., Ltd. 1935. Pp. 826. 30s.

THE book has been thoroughly revised since the last edition and a number of minor and major clinical syndromes as well as new and old references have been added. It is perhaps impossible to attain to a completely satisfactory arrangement of the subject matter of a text-book of neurology, since nervous diseases may be considered from a nosological, pathological, anatomical, or physiological point of view. Dr. Wechsler adopts the anatomical arrangement, which has the merit of being traditional, though its drawbacks are exemplified in the treatment of amyotrophic lateral sclerosis and progressive muscular atrophy in separate sections in one part of the book, while pseudo-bulbar palsy and progressive bulbar palsy are treated in separate sections in another part. It is a pity, too, that subarachnoid hæmorrhage should be described in detail under the heading "Spontaneous meningeal hæmorrhage" in isolation from intracranial aneurysm which is its commonest cause. These, however, are minor defects in a book which gives a concise and up-to-date account of disorders of the nervous system. To deal adequately with the neuroses as an appendix to a book of organic nervous disease is perhaps, in the state of our knowledge, an impossible task. Dr. Wechsler draws largely upon Freud for his psychopathological theories, and Freudian perhaps more than any other psychological ideas suffer from compression and dogmatic statement. The clinical manifestations of the neuroses, however, are well described. A valuable new feature of this edition is an introduction to the history of neurology.

The book, which is well printed and illustrated, can be recommended especially to students.

Sex in Prison

By JOSEPH F. FISHMAN, formerly Inspector of Federal Prisons. Introductory Essay by ERNST TOLLER. London: John Lane, The Bodley Head Ltd. 1935. Pp. 256. 12s. 6d.

THE reader of this book is led to suppose from an introductory note about the author that he has an extensive first-hand experience of his subject; but the book itself conveys a different impression. Though Mr. Fishman writes with a delicacy which is perhaps intentionally absent from a short introduction supplied by Ernst Toller; though he has ideas about prison reform which, he declares, would appear advanced to American penologists, his account of the sex life of prisoners is superficial and repetitive.

Much of the information is second-hand, and there are too many references to the works of sociologists and psychiatrists who have had no direct contacts with prison life. The book is entirely based upon American material, and deals almost entirely with men. It would have been more effectively written by a prison doctor of experience whose daily work brought him into intimate personal contact with prisoners.

The Spleen and Resistance

By DAVID PERLA, M.D., Associate Pathologist and Bacteriologist, Montefiore Hospital; and JESSIE MARMORSTON, M.D., Associate in Pathology, Cornell University Medical College. London: Baillière, Tindall and Cox. 1935. Pp. 170. 9s.

THE exact functions of the spleen in health and disease are ill-defined. Perla and Marmorston have made a gallant attempt to analyse the evidence concerning the importance of this organ in the mechanism of defence of the body to infection. They first review the normal anatomy of the spleen and the pathological changes occurring in infections, and then discuss its function as an organ of macrophage tissue, its rôle in antibody formation, and the effect of splenectomy in animals on natural resistance. They show clearly that splenectomy in many species of mammals converts a latent infection into manifest disease. The importance of this conclusion should be appreciated by workers in many different fields. It becomes, for instance, questionable, in view of the facts now collected, whether the spleen plays the rôle in hæmoglobin formation previously attributed to it; for this hypothesis was based upon a study of iron metabolism in splenectomised animals in which the presence of latent infection had not been excluded.

Though the impossibility of drawing definite conclusions must have made the writing of this monograph depressing, the authors will, without doubt, earn the gratitude of other workers for their painstaking and critical review of all available evidence.

The Foundations of Human Nature

By J. M. DORSEY, M.D., Associated Professor of Psychiatry, University of Michigan Medical School. London: Longmans Green and Co., Ltd. 1935. Pp. 488. 12s. 6d.

ON p. 30 of this book the author, who is associate professor of psychiatry in the University of Michigan Medical School, remarks that "the average man" is "only vaguely aware of the rich meanings and potentialities pervading the deep stirrings within him." And as he reads further the average man may congratulate himself in feeling that he has something better to do than wonder whether (p. 32) he "thinks and acts in harmony with the spirit of developmental history." In such wise the book goes on. The editor warns us that it will not make light reading. It certainly does not. The remarkable thing is that 400 pages of sheer wordiness lead to such excellent and familiar common-sense conclusions as that the best place for a child is where he loves the grown-ups and they love him, and that to be religious is to act naturally. But do these simple truths need so much rigmarole?

"The Biology of the Individual," by J. Ramsey Hunt and others, of which a review appeared in our issue of Nov. 23rd (p. 1182), is published in this country by Messrs. Baillière, Tindall & Cox.

THE LANCET

LONDON: SATURDAY, DECEMBER 7, 1935

THE RENAISSANCE OF MEDICINE

"The aims of medical science . . . are to increase and perfect our knowledge (with a view to its control) of disease in man, and equally our knowledge of man in disease, by every legitimate means of science and art at our disposal."

THIS definition is taken from the inaugural lecture delivered on Nov. 26th by the new regius professor of physic at Cambridge, and already available, attractively produced, in book form.¹ Prof. RYLE is satisfied that the vast majority of honest workers, whether at the bedside or in the laboratory, subscribe to this ideal of medical science; excepting only those few who have made a trade of their art or who through some combination of mental peculiarity and faulty education indulge in cranks, or develop a fixed idea not in accord with ascertained facts. His further contention, that many who have the proper aim in view exhibit defective standards of accuracy and of judgment in interpreting evidence, is not likely to be disputed, though the proportion of the whole profession to which these criticisms are applied will vary with the prejudices of the commentator. While none regret the passing of the convention of infallibility at one time fashionable among physicians, some hold that the habit of mind that refuses to recognise failure and bases practice on the memory of successes that may well have been fortuitous has its uses, and can be disturbed only at the risk of still further diminishing efficiency by damaging self-esteem. That the "scientific" critic of the medical practitioner tends to take little account of the hourly need to comfort and cheer the patient makes it easy to ignore or even to ridicule his comments. But when such strictures receive corroboration from one who, like Prof. RYLE, is well aware of the dangers of discouragement at the present stage of medical practice, it is well to take notice. He wastes no abuse on those "whose judgment is continually crippled, rather than gradually amended, by the inherent difficulties of their subject and the exacting conditions of their lives" but seeks to ascertain to what primary errors their shortcomings are due. His verdict is, briefly: (1) faulty selection of men, or misdirection of their energies after qualification; (2) complicated and unwieldy systems of education and examination; (3) the spread of the cult of specialism. It is with the last error that he is here concerned, condemning, of course, only excessive, premature,

and misdirected specialism and the lack of a central controlling philosophy to hold the reins of the restive younger sciences. Mingled with countless examples of good and wise industry, his practice has brought all too frequently before him—

" . . . instances of operations unnecessarily undertaken or advised, of treatments injudiciously selected and forecasts unfairly given, not because of the inherent difficulties of medicine which tax us all, but simply because the nature and meaning of common symptoms have been insufficiently appreciated; because new machines and tests have been allowed to usurp the function of eye, or ear, or hand, or native wit; because the psychology of a patient has been misread or neglected in the previous estimates; or because he or she has never been viewed as a "whole" man or woman, and the disease never studied as a "whole" disease. All too commonly the puzzled practitioner has been persuaded into unwise diagnosis or action by a laboratory or radiological opinion unjustified because it has been given without reference to or knowledge of the general situation, which includes both organism and environment, part and whole."

What steps can be taken to restore a balanced outlook, and to promote healthy, well-directed, and correlated specialism rather than isolated pigeon-holed research by men whose initial education has lacked breadth and who are deprived by the divorce of ward from laboratory of the stimulus they most need? In seeking an answer to this main problem Prof. RYLE examines some of the recent achievements in medicine, notably those of BANTING, MINOT, LAIDLAW, and LEWIS. He finds that commonly the clinician has made himself his own experimentalist or that the collaboration between experimentalist and clinician has been so intimate that they may almost be said to have worked with one mind. In a modest reference to his own part in the investigation of spirochaetal jaundice by ADRIAN STOKES during the war he points out the close association between pathologist and clinician. "Stokes was in my ward and I was in his laboratory day by day. He saw my cases. I saw his guinea-pigs." The disease in man and the experimental animal were critically compared; observations were shared, the material and work were concentrated in one place, and results and proofs followed speedily. Such favourable opportunities for problem-sharing can hardly be provided in the hospitals of great cities as at present organised; nor has Prof. RYLE confidence that the appointment of whole-time research physicians necessarily brings in its train facilities for intimate collaboration with other scientific departments. It is thus the university with a flourishing medical faculty and a well-equipped hospital that he regards as the most hopeful soil for the culture of clinical science. Where there are already assembled anatomists, physiologists, pathologists, and biochemists, and the finest facilities for teaching and research, it is only reasonable that the circuit should in due course be completed by an active department of clinical medicine. The unit here visualised is not designed for the instruction of undergraduate students but for the provision of opportunity, guidance, and material for the training of small

¹ *The Aims and Methods of Medical Science*. By John A. Ryle, M.A., M.D., F.R.C.P., Regius Professor of Physic in the University of Cambridge; Consulting Physician to Guy's Hospital, London. Cambridge University Press, 1935. Pp. 44.

selected groups of young qualified men. No attempt is made in this inaugural lecture to enumerate the possible interests and functions of such a department, but it is indicated that the study of symptoms, their nature and their purpose, by more precise methods should be a main consideration; that intensive and continuous study of common diseases should generally be preferred to isolated research on rare ones; and that therapeutic trials might constitute a practical service. The more accurate portraiture of diseases, improvements in diagnostic and prognostic methods, and studies of innate predisposition would provide appropriate tasks, with a follow-up system as an essential element of the scheme. Incidentally the services of the department to the hospital could only be stimulating and salutary; there should be no artificial separation between its functions and those of the visiting and resident staff, whose members would in fact complete the unit.

Prof. RYLE's fine conception of clinical science, which he recapitulates, is already known to our readers.² It differs from that of Sir THOMAS LEWIS³ mainly in the relative importance attached to observational as opposed to experimental methods. We are reminded (as LEWIS indeed freely admits) that there are necessary and rather strict limits to the possibilities of experiment in sick persons; it is pertinent to refer back to the words "by every legitimate means" in the definition quoted above of the aims of medical science, for it is our pride in this country to interpret them in a most rigid sense. Moreover, as Prof. RYLE points out, the types of disease which at present lend themselves to clinical experiment are few in number; it is rarely possible to reproduce, to vary, or to measure symptoms at will. But apart from these limitations of the experimental method in the human subject, it is clearly Prof. RYLE's conviction that precise and intensive methods of observational study are not yet and will not soon be exhausted. This message commands attention. We cannot doubt that it will receive it; that he will be offered scope to develop his ideas at Cambridge as facilities become available, and that his school will do its share in making "the ward, with its associate out-patient clinic and laboratories, once more both the starting and the rallying point of many researches."

STREPTOCOCCI AND PUERPERAL INFECTION

HÆMOLYTIC streptococci are found much more often in carriers than in cases of acute infection; indeed, no other organism shows so high a disproportion between carriers and disease. This fact, and the immense variety of infections for which they are responsible, have been the chief reasons for suspecting that all cocci rightly to be described as *Streptococcus pyogenes* are not the same. Hence the evolution of an increasingly complex series of tests whereby it was hoped to classify pathogenic types, and to differentiate

from them others of less or no importance in human disease. Having qualified for serious consideration on morphological and ordinary cultural grounds, a streptococcus passes into a more select though still extremely wide category by being shown to form a soluble hæmolysin, and is then examined as to its capacity to lyse fibrin, to ferment a series of carbohydrates, to hydrolyse sodium hippurate, and to grow in the presence of bile. The wider a range of tests of this kind, the more impracticable does their routine performance become and the more confusing their results. Carried out in toto on a large series of strains, these tests have afforded useful indications; but individually their value is limited.

Serological study has met with even greater difficulties, and years of effort have gone to the definition by GRIFFITH¹ of no less than 27 types distinguishable by agglutination tests. Of the ultimate individuality of a streptococcus this method is and will probably remain the only criterion; by no other means is it possible certainly to identify the source of an infection and to trace the spread of an epidemic strain. But few workers are in a position to apply this method, and its large-scale application involves immense labour. What is needed for many purposes is some cruder test, easy of application which will clearly distinguish strains highly pathogenic for man from those which are not. This requirement is met by the precipitin test of LANCEFIELD,² which relegates hæmolytic streptococci into a small number of groups (now unfortunately showing signs of considerable extension) among which strains causing serious infections in man fall always into Group A. Results obtained by this method correspond with those of the elaborate series of biochemical tests formerly in use, and seem competent to replace those tests altogether. An opportunity is thus afforded to restudy the distribution of hæmolytic streptococci in carrier sites with much more significant results. Some useful spadework in this direction is reported in a series of papers from Queen Charlotte's Hospital, where the exclusive significance of Group A in relation to serious puerperal infections has previously been verified. A large number of strains from throat carriers has been classified by Dr. HARE,³ who finds that of streptococci from this source about a third belong to Group A; or if only those strains are included which have been shown to form soluble hæmolysin, two-thirds. Dr. HARE and Dr. MAXTED⁴ have also investigated the possibility that dangerous streptococci may be present in the faeces, a doubtful question of the utmost practical importance in seeking to explain the origin of puerperal sepsis. They found no Group A strains in the faeces of 100 normal parturient women, but recovered them from the faeces of 20 per cent. of cases of scarlet fever. It is therefore apparently possible for streptococci in the throat to reach the anus alive, although uncertain in what numbers or under what

conditions. It seems desirable that the faeces of a series of throat carriers should be repeatedly examined in order to get further light on this possibility. According to COLEBROOK, MAXTED, and JOHNS,⁵ no Group A strains were found on the perineal or peri-anal skin of 160 women—another piece of evidence suggesting that the bowel is an unlikely source of infection, although here again the bacteriological state of the throat was not actually known. In these studies, of course, the delicacy of the cultural technique is all-important; improved technique, if such is possible, might reveal the presence of small numbers of streptococci more frequently. In this paper it is reported, on the other hand, that Group A strains were found on the skin of the hands in 7 out of 181 normal persons (3·8 per cent.); their presence in this situation is attributed (reasonably, but without actual evidence) to contamination from the upper air-passages, and since the genital tract may thus hypothetically be infected from the throat by a route other than the alimentary canal, it is suggested that measures should be taken to disinfect the mother's hands during labour. This is perhaps an example of those more extreme precautions which do not find favour generally, and indeed may defeat their object by arousing ridicule, if only among less serious students of this difficult problem.

While bacteriologists pile up large volumes of data bearing on the aetiology of puerperal sepsis, obstetricians are still by no means of one mind on this matter, and there are many who still disregard aerial infection and deny the throat the all-important place given it in these papers as a reservoir of infection. We publish on p. 1287 an article by Dr. PHYLLIS CONGDON which offers further evidence that the source of puerperal infections is sometimes the throat of someone attendant on the patient. Her results differ from those of previous workers in the frequency with which a strain of streptococcus identical with that in the uterus was found in the throat of the patient herself; it should be pointed out that this does not necessarily mean auto-infection, since both throat and uterus may have been infected from elsewhere. Do findings such as these constitute a sufficient case for a bacteriological overhaul of all attendants, and prospective attendants, on women in labour, and the exclusion of those found to be carrying Group A streptococci? This proceeding would certainly have some very inconvenient results.

THE EXAMINER AT BAY

DURING the last century examinations of innumerable species, created by private and public bodies, have sprung up here, there, and everywhere, and have grown so luxuriantly that they overshadow not only our education but the social system of our country. Examinations form a barrier between elementary and secondary education, between secondary education and the universities; they confront the aspirant to pro-

fessional and many business careers. How far do they let through the right people? This is a question that troubles both teacher and parent, examiner as well as examinee. The latter is apt to feel that the system is one which does not do justice to his abilities; that Mr. Smith, for instance, can win approval by means of his retentive memory, whereas he, Mr. Jones, lacking that faculty, is unable to demonstrate his innate superiority in mental power. But another question, of at least equal importance, to which less attention has been paid, is this: does the fate of Smith or Jones depend to any appreciable extent upon the inevitable variability between the opinions of different examiners, or upon the variability of the same examiner at one time and another? If an examiner considers Jones worthy of first-class honours in 1935, would he place him in precisely the same category if presented with exactly the same answers in 1936? If one examiner is of opinion that Smith must be ploughed, will that opinion be endorsed by others equally competent? In fact, how far does the element of chance enter into the results of our public examinations? Into this question exhaustive inquiries are now being made. As the outcome of an International Conference on Examinations held at Eastbourne in 1931, committees were set up in England, France, Germany, Scotland, and Switzerland, their investigations being financed by grants from the Carnegie Corporation through the International Institute, Teachers College, Columbia University, New York. The English committee, which comprised distinguished professors of education and psychology, was presided over by Sir MICHAEL SADLER, and Dr. E. C. RHODES, reader in statistics at the London School of Economics, was engaged to act as their statistician. Their main work is being recorded in a volume entitled "The Marks of Examiners," now in course of printing, but the principal results of the investigations are shown in summary form in a pamphlet issued this week.¹ The position revealed, as shown by what follows, is, to say the least of it, very disquieting.

The methods of inquiry adopted appear eminently satisfactory. The scripts investigated were all actual scripts which had been written by candidates in the course of an ordinary examination—e.g., for School Certificate, a college scholarship at one of the older universities (English essay), and an honours degree (mathematics and history). The examiners by whom these papers were marked were all persons with experience of the kind of examination investigated, and they were able to mark the papers under less pressure in respect of time than ordinarily prevails at an examination, so that the marks may be regarded as expressing their deliberate opinion. Furthermore they were all paid, so that the conditions were as near reality as possible. As examples of the results reached the following may be quoted. When fourteen experienced examiners re-marked independently fifteen School Certificate history

⁵ Colebrook, L., Maxted, W. R., and Johns, A. M.: *Ibid.*, p. 321.

scripts, which had all received the same "middling" mark by the School Certificate authority concerned, they allotted no less than 43 different marks varying from 21 to 70 (out of a maximum of 96). But worse was to follow. The same papers were re-marked by the same examiners (excluding one) 12-19 months later. It is stated that they gave assurance that they had kept no record of their previous work, and, as the authors caustically add, "this was indeed obvious from the results." For on each occasion the examiners gave a verdict of Failure, Pass or Credit, and in 92 cases out of the total 210 the individual examiners gave a different verdict on the second occasion from the verdict awarded on the first! In 9 cases candidates were moved two classes up or down, while one examiner changed his verdict on 8 candidates out of 15. It seems likely that such extreme variability might be reduced by the construction of a board of examiners with an agreed and detailed marking scheme, and this plan was tested with various School Certificate papers as basis. For example, with French, two 2-hour papers were marked by two boards of examiners, the first board (A) having adopted 5 general directions and 640 detailed directions for Paper I. and 290 detailed directions for Paper II. The scheme of Board B included 700 detailed items for Paper I. and 300 for Paper II. In spite of these complex schemes the returns of the individual examiners showed that the number of Failures varied from 6 to 15, of Passes from 7 to 16, of Credits from 21 to 30, and of Distinctions from 1 to 9. Agreement was reached between the six examiners of Board A on the awards to only 27 candidates out of 50, and between the examiners of Board B in regard to only 30 out of 50. Similar results, though somewhat less discrepant, were reached with chemistry papers. With English papers seven examiners were employed. There was only 1 candidate out of the 48 to whom all seven examiners awarded the same class. One examiner ploughed 19 candidates, while two ploughed none; one gave 12 special credits and three gave none. On one paper a candidate was ploughed by six examiners and awarded a credit by the seventh. Even with a university mathematical honours paper the range of marking is considerable. With six examiners marking the same scripts the range of marks awarded, out of a maximum of 300, ranged for particular candidates from 81 to 145 and from 118 to 175—i.e., from a certain plough to a probable pass, while other candidate vary in the honours that they would have been awarded.

A particularly interesting experiment involved a viva-voce examination, of the type used in Civil Service examinations to test "alertness, intelligence, and general outlook." For this purpose two boards of examiners were set up, consisting of persons of experience, used to judging candidates by interview. Applications were invited from university students, aged 21-23, certified by the university authorities to be suitable as candidates for the junior grade of the administrative class, Home Civil Service (this is the technical name for the appointments of the highest

grade in the Home Civil Service, open to competition). To ensure an adequate stimulus a prize of £100 was offered on the results of the viva-voce examination. Sixteen candidates were thus individually examined by each of the two boards for 15-30 minutes each. After the interview each examiner recorded the mark (out of a maximum of 300) that he or she would personally award, and that having been written down the board agreed upon a mark representing the view of the whole board. The results of this very careful experiment show not only wide differences of opinion between the individual examiners but between the boards. The candidate placed first by Board X was placed thirteenth by Board Y, and the candidate placed first by Board Y was placed eleventh by Board X. The extreme differences between the two boards' estimates of the candidates' merits point, the authors are driven to conclude, to the unreliability of the interview test. Sir PHILIP HARTOG, who was present as an "impartial and silent observer" at the proceedings of the two boards, formed the opinion that while they were equally skilful in cross-examining in such a way as to reveal the weaknesses of candidates, it was largely a matter of chance whether they struck on a topic about which a candidate felt so strongly that he was able to display his individuality. The lucky recipient of the £100 (and the results of the test suggest we must stress the word *lucky*) was placed second by one board and fourth by the other.

To what conclusions does this important piece of work lead us? It is clear that the part played by chance in the verdicts given at different examinations on which careers depend must often at the present moment be a great one. No doubt the consideration of borderline cases by examination authorities does materially diminish the chances of a candidate being wrongly rejected, but it appears from this report that some candidates may be placed in error below the borderline, and thus their case is never reviewed, while others may win certificates of efficiency when they should by rights have been rejected. The employment of boards instead of individual examiners diminishes the element of chance but does not remove it. Then should examinations be abolished? The committee definitely think not. They believe that as a test of efficiency the system is necessary, but that only by careful and systematic experiments can methods of examination be devised "not liable to the distressing uncertainties of the present system. No doubt investigations like those recorded by our committee, and administrative experiments in allowing teachers, in conjunction with Government or university inspectors, to 'brand their own herrings,' would involve expenditure, but such expenditure and experiments would be justified in the public interest." The present report must give everyone engaged in the conduct of examinations furiously to think, and in the interests both of the examined and the examining it is to be hoped that the further experimental work the committee plead for will be developed.

ANNOTATIONS

A FOOD POLICY

Is not the time ripe for the initiation of a comprehensive national food policy? was the question asked by Sir Gowland Hopkins in his presidential address to the anniversary meeting, last Saturday, of the Royal Society. That underfeeding and ill-feeding exist he was sure, although he admitted the difficulty of measuring their extent, and after a diligent study of available evidence he was left with the impression that the situation called for further and immediate action. It seems that the Expert Commission on Nutrition, appointed by the League of Nations, which held its first meeting in London last week¹ under the chairmanship of Prof. Edward Mellanby, drew up a list, in order of priority, of the problems for future study at various scientific institutes, with a view to practical progress. This is the first time that nutrition has been dealt with at an international conference by European and American authorities, and the members of the conference will remain in touch with each other through the Health Organisation of the League of Nations. The League of Nations Council has appointed a joint committee for the study of the problem of nutrition, which is to present a general report to the Assembly in 1936, and the report of this week¹ will be transmitted to this joint committee, whose first meeting will take place at the end of this week. The experts who have drawn up the present report will be represented by their chairman, Prof. Edward Mellanby, and Prof. E. V. McCollum; or, if either of these is prevented from attending, by Sir John Orr or Prof. Mary S. Rose.

SMALL-POX AND ALASTRIM

THE relationship of alastrim to variola major still remains puzzling despite a very considerable body of work on the matter. The subject is not one of merely academic interest; it constitutes a major problem in public health. Although there are certain clinical differences between the two diseases, the identity of the two viruses seemed established by laboratory workers by means of animal inoculations, allergic tests, and serological investigations. The question of differentiation is, however, one of great complexity, as it concerns the antigenic structures of the two viruses. This relationship is linked with that of vaccinia. Additional data from the morphological standpoint have been provided by the studies of Dr. C. Magarinos Torres, of Rio de Janeiro, which have appeared from time to time during the last few years in the *Comptes Rendus* of the Paris Société de Biologie. These data formed the main subject of his Lloyd Roberts lecture delivered before the Royal Society of Medicine last week and briefly reported in our columns (p. 1236). Differences are stated to exist in the histological appearances of variola and alastrim, and, in especial, of the inclusion bodies within tissue cells produced by these diseases. Unfortunately the nature of such bodies, whether of the typical Guarnieri type or not, cannot be regarded as established. The commonly accepted view is that they are the products of tissue-cell reaction to the influence of infection by the virus. In the opinion, however, of E. W. Goodpasture and his co-workers,² studying the lesions on the chorio-allantoic membranes of chick embryos produced

by vaccinia of neurotesticular origin, there was evidence that the Guarnieri bodies represent, in part at least, colonies or masses of elementary (Paschen) bodies. It is prudent therefore to suspend judgment on the significance of Dr. Torres's observations. The pathological findings in alastrim are valuable and the lecture should stimulate research into the histology of this disease, and particularly research into the nature of the inclusion bodies associated with the tissue changes in all three linked viruses.

BLINDNESS IN THE U.S.A.

It is not easy to make a statistical survey of the causes of blindness in any country, and Mr. Harry Best shows us in his book¹ that the difficulties in America are exceptional. The survey, to be of practical service, must include those with considerably more vision than bare perception of light, and it is by no means easy to draw the line between the blind and the partially blind. Moreover, in America, each State has its own regulations concerning blindness, and naturally these differ. The attempt to compile elaborate and detailed statistics applicable to the United States as a whole would therefore appear to be futile. The proportions of blindness due to different causes can only be stated roughly, but taking the main categories they appear to be approximately the same in America as in England. For example, blindness from ophthalmia neonatorum is diminishing owing to greater care in prophylaxis. The incidence of trachoma is now small except among the Indians. At early ages congenital cases form a considerable proportion of the blind; in middle life accidents loom large, and in later life the main causes of new cases are cataract and glaucoma. In this connexion it would be interesting if it were possible to trace the effect of improved operative treatment on the statistics of blindness, but as far as we know this has not been attempted.

Taking the United States as a whole, about half of the total blind population are supported either by their own private means or by their families, relatives, and friends. The total amount of relief from almsgiving or organised charity is not assessed. A few of the blind are cared for in special homes, and the most frequent form of public relief is maintenance in almshouses, where about 6 per cent. of the total number of blind are provided for. In some States pensions for the blind exist under the direction of the several counties with more or less of State supervision.

The problem is still in the experimental stage, being in the hands, not of the Federal Government, but in those of the various States. On the whole public economic assistance to the blind in the United States appears to be less systematised than in England where progress in this matter has been steady since the passing of the Blind Persons Act in 1920. Schools for the blind were opened about a hundred years ago in Boston, New York, and Philadelphia, and other States gradually followed. Their origin was due to private initiative, but it was not long before Government grants were obtained. Since 1920 State schools for the blind exist in most States, and it is estimated that three-quarters of the blind population between the ages of 5 and 24 are

¹ *Blindness and the Blind in the United States*. By Harry Best. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1935. Pp. 714. 2ss.

educated in these. In the large cities a few ordinary day schools have special classes for the blind but, on the whole, owing to the absence of any compulsion, in many States the education received is, according to Mr. Best, not very satisfactory. Until comparatively recently various systems of raised type were employed, but in 1916 a satisfactory system of Braille was adopted by the American Association of Instructors for the Blind and is now general. Besides oral instruction and the acquirement of Braille reading, physical training is especially important. Musical instruction always occupies a prominent place in the work of the schools, and a number of piano tuners are turned out. Industrial training includes sewing, knitting, chair-caning, brush- and rug-making, basketry, carpentry, and cooking. An interesting section deals with the blind workshop movement, and there are others dealing with indemnities paid for loss of sight through suits at law, through insurance, and through Workmen's Compensation laws.

BIOPSY OF STERNAL MARROW

It is said that Türk, when questioned about the pathology of a certain "blood" disease, haughtily replied: "Sir, I am a peripheral hæmatologist." To-day few people are rash enough to make a diagnosis in obscure cases without some knowledge of the character of the hæmopoietic tissue; and recent observations show that such knowledge may well be gained during life by the method of sternal marrow puncture. Dameshek¹ and also Young and Osgood² have lately reviewed large series of cases studied in this way. Dameshek obtained his marrow by means of a special small trephine enabling him to prepare both smears and sections, while Young and Osgood removed through a lumbar puncture needle enough marrow to make smears. The results of the two methods seem to agree closely. Many conditions presenting anemia as an outstanding symptom fail to provide signs, either clinical or hæmatological, that allow of an exact diagnosis. This is particularly true of aleukæmic myelosis. Thus, if a large spleen is found in patients with anemia and leucopenia, splenic anemia is usually diagnosed. If the anemia is megalocytic, pernicious anemia is accepted as a diagnosis; if petechiæ and hæmorrhages are present, thrombopenic purpura is considered; and if there is a conspicuous leucopenia with few neutrophils, agranulocytosis is suggested. In such cases of obscure anemia associated with leucopenia and thrombocytopenia, bone-marrow biopsy frequently shows that the marrow may be extremely cellular, though the peripheral blood itself is almost devoid of white cells. "Agranulocytosis," which fails to respond to pentose nucleotide, is often, probably, aleukæmic leukæmia; many cases of "pernicious anemia" which do not improve on liver fall into the same group; while Dameshek found that the great majority of a series of cases diagnosed as Banti's disease should on biopsy examination be grouped as aleukæmic leukæmia. Apart from its value as a diagnostic aid, the examination of marrow smears should give us information useful on a more academic plane. For example, Osgood and Young were able to demonstrate numerous stippled red cells in a case of lead-poisoning, whereas Aub and his associates had previously claimed that stippling is not seen in marrow cells, and is therefore, at least in lead-

poisoning, a sign of degeneration. It is clear that biopsy studies of sternal marrow, if undertaken by observers with considerable experience of the appearance of normal marrow, will be a valuable addition to the more usual technique of "peripheral hæmatology."

RENAL, CORTICAL NECROSIS IN PREGNANCY

Diffuse and almost complete symmetrical necrosis of the renal cortex is fortunately rare among the complications of pregnancy. Few pathologists have seen more than two or three examples, and its pathogenesis is still obscure. Dr. S. De Navasquez's histological study¹ of a series of 15 cases—3 from Guy's Hospital and the remaining 12 collected from other sources—has given him an opportunity of detecting and bringing into prominence what appears to be the essential histological lesion. His analysis shows no evidence of a pre-existing nephritis. The changes, which closely resemble those of anæmic infarction, must be referred to a vascular mechanism; and here it is of importance that De Navasquez discards the theory of local thrombosis both from the structure of the vessel contents—which, he says, are no more than conglutinated red and white corpuscles without fibrin or platelet deposition—and from the study of two early cases in which these so-called thrombi were absent. On the other hand, he finds that a variable degree of necrosis of the intralobular arteries and their branches can be detected and regards this as the primary change in these kidneys. Comparison shows that it is distinct from the necrosis that inevitably takes place in the walls of vessels included in areas of true renal infarction. It is of interest that De Navasquez finds identical histological changes in the specimens from a case of dioxane poisoning supplied by Dr. H. Barber. This is perhaps the only agent of known chemical composition that has as yet been shown to produce bilateral diffuse cortical necrosis of the kidneys; it is certainly not known how such necrosis is produced in pregnancy. De Navasquez states, however, that it has been caused experimentally in rabbits by means of bacterial toxins and that we may expect a future communication upon the results of this work.

URINARY INFECTIONS OF THE NEW-BORN

In the first week of life it is not uncommon to find a baby feverish and passing very little urine. The condition will often respond quickly to extra fluid by mouth or (if there is already anuria) intravenously. How many of these cases represent a primary disorder of the urinary apparatus and how many the so-called "dehydration fever" it is hard to say. Dr. W. S. Craig² does not mention the latter possibility; but his general study of urinary infection in the new-born is one which deserves attention. First he determined normal standards by examining 200 specimens of ordinary urine from healthy non-febrile infants between the ages of twelve hours and fourteen days. In 163 of these no cellular or other solid elements could be discovered; in the remaining 37 epithelial cells were the commonest finding, and in 10 there were polymorphonuclear leucocytes, never in greater number than one in 10-15 high-power fields. Of 43 catheter specimens examined bacteriologically, 7 gave isolated discrete colonies of *Bacillus coli* on culture, and 3 gave sparse growths of other organisms. In contrast to these normal findings Craig gives the results of examination of the urine

¹ Dameshek, W.: Amer. Jour. Med. Sci., November, 1935, p. 617.

² Young, R. H., and Osgood, E. E.: Arch. Internal Med., 1935, lv., 186.

¹ Jour. Path. and Bact., November, 1935, p. 385.

² Arch. Dis. Childhood, October, 1935, p. 377.

of 61 infants considered on clinical grounds to have some disorder of the urinary tract. Numerous pus cells were present in 48 cases (5-140 per field) and organisms were sometimes found in those without pus cells; the urine contained casts in 14 cases and there were 7 with a mixed infection. That briefly summarises the pathological findings. Clinically the chief features—roughly in order of frequency—were fever, anuria, or a big decrease in urinary output, thirst, restlessness and irritability, changes in colour to a dusky-grey, sweating, vomiting, oedema, collapse, and terminal convulsions—the last occurring in 10 per cent. of cases. Of the 61 children, 9 died never having left hospital, but recovery was apparently complete in all the others. More males were affected than females—40 as against 21—which is in contrast with the findings in later life. Without offering any final solution of the problem Craig thinks that the symptoms at any rate are closely related to the excretory activity of the kidneys, and that the paucity and high concentration of the urine ordinarily passed in the early days of life may make infection easier. Treatment is directed towards promoting free diuresis. Provided there was no collapse and the general condition of the child remained good, feeding was allowed to proceed normally. Extra fluids in the form of water or weak tea were given between feeds; in the presence of collapse or high fever they were given at hourly or half-hourly intervals, and milk was temporarily excluded. Alkalis were administered as sodium or potassium citrate with an initial dose of 16-20 grains in twenty-four hours. This was usually enough to make the urine alkaline, but larger doses were sometimes needed; subsequently the dose was adjusted to maintain alkalinity. The bowel function was treated by an initial dose of castor oil (30 minims) and bowel lavage if the motions were fetid; and local warmth was applied to the lumbar region. Among the babies whose career was followed after discharge many were found to pass *B. coli* and pus for several weeks after all symptoms had disappeared.

STANDARDISATION AND ESTIMATION OF VITAMIN A

THE success of the International Conference on Vitamin Standardisation, held in London last year, was largely secured by careful preparation in this and other countries. This preparation involved much experimental work of the sort in which parallel tests are made in several laboratories with the same material. Such investigations have to be coördinated, and this was done in Great Britain by a subcommittee for each vitamin, appointed by the Accessory Food Factors Committee, which is itself appointed jointly by the Medical Research Council and the Lister Institute. Corporate studies of this kind are very difficult to publish. The contribution of a single worker or laboratory is often quite inadequate when described by itself, or at any rate loses much weight by standing alone. On the other hand, if all the contributions are collected and published together, the attempt to harmonise them may be almost hopeless. In the latest special report of the Medical Research Council¹ such an attempt has been made for the experimental work done by British workers in connexion with the international standard for vitamin A. Studies from different laboratories are collected, and it has proved possible to weld them

into a reasonably coherent form. They included a search for a suitable solvent for the crystalline carotene, acting as the international standard. This solvent had to be one in which the carotene remained stable and from which it was well utilised by the experimental animals. Coconut oil with added hydroquinone was selected. Then it was necessary to ascertain the biological value of pure β -carotene, which was recommended as international standard to replace the impure mixture of carotenes which was provisionally adopted as standard by the first conference in 1931. This was a very important value which could be ascertained only by a biological test. The error in such biological estimations is great and there was corresponding advantage in having a value based on the results from several laboratories. In some substances, such as cod-liver oil, there is no carotene, the only source of vitamin-A potency being the vitamin itself. A spectroscopic method of estimating vitamin A in such material had come into use and the report includes joint studies on the reliability of this test and on the factor which should be used for converting the results of the spectroscopic test into international units of vitamin-A potency, as determined by the biological test. A figure for this factor was fixed, and adopted by the conference—perhaps rather prematurely. The report also contains studies on cod-liver oil as a subsidiary international standard for vitamin A, in addition to β -carotene. This section includes some interesting comparative figures in which biological tests for vitamin A were made on the same material not only in this country but also in American and several European countries, and good agreement was achieved. Finally it reproduces in full the report of the International Conference on Vitamin Standardisation, which is not very easily accessible otherwise. It is gratifying that the recommendations arising from the corporate studies reported in this book were embodied in the decisions of the conference.

HEDGEHOGS AND THE COMMON COLD

THE search continues for an experimental animal susceptible to the common cold. Human volunteers and chimpanzees, while definitely susceptible, cannot be used to solve most of the major problems of the disease. Interest attaches, therefore, to a preliminary communication made by Mr. J. T. Edwards, D.Sc., to the meeting of the section of comparative medicine of the Royal Society of Medicine held at the Lister Institute on Nov. 27th. Observations on foot-and-mouth disease formed the starting-point of his studies; the virus of this disease will infect hedgehogs by the intranasal route and causes in them a high mortality. As the virus is passed in series, the rôle of secondary invaders, such as *pasteurella*, *salmonella*, and particularly *Bacillus bronchisepticus*, becomes more prominent. The virus, in fact, activates the normal nasal flora of the hedgehog and this may lead to the animal's death from bronchopneumonia or septicæmia. "It was possible," argues Edwards, "that if material derived from cases of common cold contained a filtrable virus, this virus might in a similar way be found to prepare a way for certain subpathogenic bacteria on the nasal mucosa of the hedgehog to obtain a foothold, multiply, and set up catarrhal lesions." Filtered and unfiltered secretions from three cases of acute coryza in man were inoculated into hedgehogs under ether anaesthesia, and Edwards reports that a number of animals showed an increase in their nasal discharge after inoculation, and that in some of them catarrhal

¹ Reports on Biological Standards. IV. The Standardisation and Estimation of Vitamin A. Edited by E. M. Hume and H. Chick. Med. Research Council, Spec. Rep. Ser. No. 202. London: H.M. Stationery Office. 1935. Pp. 61. 1s.

lesions were found histologically in the mucosa covering their turbinates. *B. bronchisepticus* was the organism most commonly recovered from affected hedgehogs. Broth and "heated cold filtrate" did not produce comparable effects. Passage in hedgehogs was apparently successful for three serial transfers.

At the same meeting Dr. C. H. Stuart-Harris said that in consultation with Dr. Edwards he had been carrying out similar experiments at the National Institute for Medical Research at Hampstead. He was able to confirm the fact that hedgehogs inoculated intranasally with common-cold secretions develop an increased nasal discharge. He hesitated, however, to conclude at this stage that the effect was a specific one, for three reasons. First, normal hedgehogs show great variation in the amount of their nasal secretions; secondly, he had suggestive evidence that inoculation of *B. bronchisepticus* alone could increase the amount of secretion; and, thirdly, he had been unable to correlate the amount of discharge with the histological findings.

This line of approach to the common cold is an interesting one, but the interpretation of the results must be much more difficult than in most work on viruses, for variation in the nasal flora of hedgehogs is a factor very difficult to control. The results must therefore be regarded with great caution, indicating at most that further work along these lines is desirable. It may be added that as Edwards has failed to infect ferrets and mice, the virus, if virus there is, is probably distinct from that of influenza.

FEVER HOSPITALS, PAST AND FUTURE

IN his presidential address to the fever group of the Society of Medical Officers of Health on Nov. 29th, Dr. E. H. R. Harries made good his claim that the modern fever hospital would, in relation to its special purposes, bear comparison with institutions more widely known, even if the attempt to reduce the incidence of endemic infectious disease by the isolation of a minority of infected individuals had failed. The great decline in the enteric group was admittedly due entirely to sanitation; there had been no appreciable reduction in the incidence of scarlet fever, diphtheria, measles, or whooping-cough, and the fall in the mortality of the common specific infections began before the provision of fever hospitals became general. The reduction in mortality of diphtheria Dr. Harries attributed primarily to the introduction of antitoxin, combined with sound nursing; it had now probably reached its limit. Some may not agree with him that the decline in fatality commenced steeply 40 years ago—for during the last decade of the nineteenth century diphtheria mortality was higher than in the preceding two or subsequent three decades—but none will dispute that without skilled nursing, which ordinarily can only be obtained in hospital, antitoxin may be of little avail. Dr. Harries here lends his weight to the belief, now becoming general, that overcrowding in wards is not economical; on the contrary, it results in a high incidence of cross-infections and in a lengthened average stay. The bed spacing which is now the rule would even thirty years ago have seemed fantastically extravagant or divinely fortuitous. All experienced hospital administrators are at one in regarding the ward management of several of the common fevers as essentially the control of infection and reinfection of the upper respiratory tract. To this end not only is adequate bed-spacing in the open ward essential, but also the segregation

of patients who constitute potential foci of gross infection. To the pioneers of a generation ago we owe the introduction of aseptic nursing, the cubicle, the chamber, the barrier, and the bed-isolation ward.

Dr. Harries had much to say for the status of the fever hospital as a training and teaching institution. The provision of specialist services, he feels, is not only necessary in the interests of the patient but wholly desirable from the point of view of the institution and the staff. The instruction in fevers included in the medical curriculum is at present quite inadequate; the work of the fever hospital requires the closest integration with that of the children's hospital and the general hospital. The time has arrived for team-work rather than individual effort. Opportunities for clinical study of many of the fevers are strictly limited in this country. Those who have had any extended clinical experience of for instance typhus and relapsing fever (and he might have added small-pox) are now few and the clinical aspect of the enteric group of infections has changed for the better. But there is still much to be learned in the wards of the fever hospital, and opportunities are not lacking for original investigation—something more than, in his caustic phrase, papers that parade the apparatus and protocols of a scientific paper. Dr. Harries would have every assistant medical officer attempt some piece of clinical investigation; and this he can do only by knowing the literature of his special subject and, where the subject lends itself to statistical control, by seeking the advice of those who can foresee possible fallacies. In the proper care of the ear during the acute specific infections Dr. Harries finds the chief prophylactic measure against deafness and deaf-mutism; it would be difficult to assess the value of otologists in fever hospitals either in terms of hearing saved or of stay diminished. The solution of the larger problem of preventing the running ear would ultimately be brought about not by the otologist alone but by his collaboration with medical administrator and clinical officer. In measles the day was not far distant when every case before discharge would be X rayed to detect signs of grave pulmonary sequelae.

COLLAPSE THERAPY IN PLEUROPNEUMONIA

THE suggestion that therapeutic pneumothorax may be of benefit in pneumonia is not new, for Friedemann treated seven cases by this method in 1921 and was able to report that each had made an uneventful recovery. Experimental support for the method was, however, not forthcoming till Lieberman and Leopold demonstrated its value in the treatment of eighteen dogs suffering from unilateral pneumonia, and compared the result with the fate of a similar number of untreated animals. Before 1934 some fifty cases, with only three deaths, had been reported of the use of the same method in human beings. Already in 1932 Dr. J. J. Coghlan related in our own columns¹ a series of cases of lobar pneumonia treated at St. Olave's Hospital, Rotherhithe, by artificial pneumothorax. The induction gave rise to something very like a normal crisis, but he found that control of the pneumonic process itself was temporary. In our present issue Dr. W. E. Robertson publishes the results obtained in a series of forty-seven cases treated at the Philadelphia General Hospital; the patients included twenty negroes and the death-rate was 43 per cent. The result would not be impressive

¹ THE LANCET, 1932, I., 13, and 1934, I., 1127.

apart from Dr. Robertson's explanation that this hospital serves the needs of the poorest, among whom ignorance, neglect, and economic stress are perennial. More favourable results are reported by Blake, Howard, and Hull² who claim four successes in four cases treated within 24 hours of the onset of the disease, and six successes out of nine cases in which treatment was begun between 24 hours and 48 hours after onset. In the three cases apparently uninfluenced by the treatment pleural adhesions were present. It should be remembered, however, that the patient who receives pneumothorax treatment at an early stage is one who has been promptly admitted to hospital. A patient who travels to hospital after the second day of his illness makes a hazardous journey and his chances have often been prejudiced by inadequate nursing before arrival. Those who have employed collapse therapy in pneumonia are agreed that its use in early stages, when pleural pain may amount to agony, brings immediate relief to the patient. A similar relief is experienced when a pleural effusion separates the parietal and visceral pleura in tuberculous inflammations. Even if the treatment effected no more than this much would have been gained. Acute pain and shallow hurried respirations at the onset of pneumonia must lower resistance and prejudice the sufferer's chance of recovery. The immediate relief of pain and respiratory distress may bring the much needed sleep and enable the physician to dispense with hypnotics. T. Klein and V. L. Tuck, also from experience at the Philadelphia General Hospital, claim³ that alleviation of pain is invariably followed by a diminution of cyanosis and a slowing of respiratory and pulse-rates. And in our present issue Dr. Cedric Shaw gives striking examples of the relief afforded to pleuritic pain by even a shallow pneumothorax.

When pneumothorax treatment has been adopted the method generally employed has been to inject sufficient air to produce a modest degree of collapse and to maintain this only for a short period, e.g., 300-500 c.cm. at induction followed by a refill some 24 hours later. It has now been suggested² that a complete collapse of the diseased lung, or at any rate a complete selective collapse, is necessary to get full benefit from the treatment. This requires X ray control and is only applicable if bedside radiography is available. To obtain adequate collapse without frequent refills and without causing dyspnoea a large initial amount is given, the air being introduced very slowly. In this way as much as 2000 c.cm. of air have been given at induction. As the air flow should not exceed 12 c.cm. or so per minute a period of between two and three hours may be required to raise the intrapleural pressure to atmospheric level. The first refill will be required within eight hours, the time selected for the refill and the number of subsequent refills depending on the pressure level at the end of the first treatment, on the volume of air already introduced, and on the clinical response. For work of this kind a free pleura is, of course, essential and it is difficult to think that the treatment is without risk. There is however reason to believe that as a palliative measure artificial pneumothorax is of definite value in the treatment of pneumonia with pleurisy. That it has curative value is open to question; the successes hitherto claimed may be of the kind commonly noted when a new remedy is introduced. Whether the period of sickness can thus be shortened and the chances of death diminished will only be determined after statistically significant

results have been reported and compared with properly selected controls. Meanwhile in preparing a scheme for the treatment of pneumonia the prudent doctor might well add artificial pneumothorax to the list of permitted remedies, with the proviso that it should only be adopted if pleural pain and respiratory distress aggravate incipient disease.

On Thursday, Dec. 12th, Dr. Cecil Wall will give the Thomas Vicary lecture to the Royal College of Surgeons of England. He will speak on the Surgeons' Company, 1745-1800.

On Nov. 26th the gold medal of the Birmingham Civic Society was presented to Sir Gilbert Barling in recognition of his services to the intellectual and aesthetic life of the city. Sir Gilbert was for twenty years pro-chancellor of the university and has been for ten years chairman of the society.

THE MEDICAL DIRECTORY for 1936 reaches us on Nov. 29th, 1935, and is as convenient and accurate as usual—perhaps a little more accurate, for during the year the Editor of the Directory notified through our columns those members of the medical profession who had not communicated to him their present address, and we were happy to collaborate inasmuch as the accuracy of the Directory is a matter of public importance. The blemishes are likely therefore this year to be more difficult than ever to find. Fortunately the Directory was warned of the general election in time to delete the list of medical Members of Parliament which would otherwise have been somewhat out of date. The numerical summary of the medical profession shows the total names in the 1936 Directory—namely, 58,094—to be an increase of 966 over last year, the increment being far the largest for nine years past. Of this increment, London is responsible for 222, the Provinces for 533, Wales for 32, Scotland for 62, Abroad for 127, and the Services for 3; while Ireland has decreased its entry by 13. We congratulate the Directory on its team-work.

A FUND FOR DENTAL AID

THE IVORY CROSS National Dental Aid Fund was established in November, 1914, by the late Miss Fletcher to provide dental aid for soldiers and sailors. To fit them for active service, and for recruits with dental defects which prevented their acceptance. It was not until November, 1915, that the War Office provided for Imperial Service men; nor did the Admiralty undertake the treatment of sailors or recruits for the Navy until January, 1916. Since the war the charity has been actively engaged in the provision of dental treatment for members of the civil population who are unable to meet the cost of such services. The work has grown to such an extent that it was thought desirable to reorganise the administration on a wider basis, and this has now been done. The council includes representatives of many other interested charities and a committee representative of the dental profession is being formed for advisory purposes. Grants in aid of dental treatment are made on the recommendation of a case committee after examination of the claims received from numerous applicants. Although the Ivory Cross is run as far as possible on a contributory basis, it is necessary to make grants to many who are unable to contribute anything, and the strain on the funds is consequently heavy. It is rightly stated that the work which the charity could carry out, had it adequate funds, is enormous. The address is 67, Wadbeck-street, London, W.1, and all communications, including applications for assistance, should be addressed to the secretary.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXX.

PROGNOSIS OF PITUITARY TUMOURS

I*

THREE varieties of tumour are found in the anterior lobe of the pituitary gland: chromophobe adenoma, acidophil adenoma, and basophil adenoma.¹ The basophil adenoma has recently been considered by Cushing as the cause of certain endocrinal symptoms, but the information so far accumulated is not sufficient to justify prognosis. In acidophil² and chromophobe adenomas, on the other hand, the course of the illness can be predicted within certain limits. Both types of tumour produce disturbances of bodily appearance and of the other endocrine glands of the body, and, as they enlarge, both tend to project upwards and press upon the optic chiasm.

Acidophil adenoma is the type of tumour that gives rise to acromegaly. This condition is recognised at a glance by the characteristic changes of external appearance. The diagnosis is easy and the symptoms manifold, and it is not surprising therefore that in acromegaly the prognosis has to cover a wide field. In *chromophobe adenoma*, on the other hand, the question of prognosis arises in a different way. The changes in external appearance produced by this tumour are far from obvious and do not distress or incommode the patient; the diagnosis is practically never made until the onset of visual symptoms and recognition of the fact that these symptoms are due to involvement of the optic chiasm. In these cases, and they are much more common than cases of acromegaly, prognosis will largely centre upon what is likely to happen to the patients' eyesight.

Methods of Treatment

Before considering to what extent these maladies can yield to treatment, it is advisable to survey the therapeutic methods so far available. Because of certain difficulties and dangers surgical attack upon a pituitary adenoma is usually limited to partial removal of the tumour, with the object of relieving pressure upon the optic chiasm. Of the other methods, irradiation by the modern high voltage X ray plant in the hands of experts has proved very useful in some cases of acromegaly, and so, to a lesser extent, has the implantation of radium or radon into the sella turcica by open operation. There is so far no evidence that irradiation is of much value in chromophobe adenoma. These are the only methods of radical treatment at our disposal. Dietetic treatment is of importance in certain phases of pituitary disease, and insulin is helpful in many cases of acromegalic diabetes, but other varieties of hormone treatment, of which many have been tried, have not yet proved successful.

Acromegaly

Acromegaly is compatible with a long and useful life. This is well illustrated by the case of Dr. Leonard Mark, who practised medicine in London with considerable distinction notwithstanding that

he was for many years afflicted with a severe degree of acromegaly, described in his book (*"Acromegaly: a Personal Experience,"* London, 1912).

What are the prospects of one who, from coarsening of his features, increased prominence of his mandible and enlargement of his extremities, is recognisable to all beholders as a sufferer from acromegaly? There is nothing so far known that can bring back his normal appearance and it is well, therefore, that he is usually not disturbed by the disfigurement, so gradual is its progress. If the disease begins before the epiphyses are united the patient will grow to gigantic proportions, and the younger he is the more intense the change. But the changes of acromegaly and acromegalic gigantism do not progress indefinitely; usually they cease after a few years, though the lower jaw may slowly project a little more, with increasing disturbance of the bite. Acromegalic patients seem particularly subject to dental caries and need constant attention to their teeth and to their bite. X ray treatment is probably of considerable value in limiting these disturbances and in diminishing the thickening of the subcutaneous tissues that is characteristic of the disease.

There are many patients with pituitary adenoma in whom slight alterations of an acromegalic type can only be found on close scrutiny, and these changes do not progress. They are cases of fugitive acromegaly² (Bailey and Cushing, *Amer. Jour. Path.*, 1928, iv., 545) and the adenomas that produce them are usually composed not solely of acidophil cells but of a mixture of acidophil and chromophobe cells. In these cases a cheerful forecast about the change of features can be given if the question arises.

Sexual Dysfunction

Both in acromegalic and in chromophobe adenoma sexual functions tend to be greatly depressed or absolutely lost. Evidence is accumulating to show that this is due to pressure of the tumour upon the basophil cells of the anterior lobe, and W. R. Henderson (*Endocrinology*, 1931, xv., 111) has shown that it is least likely to occur when the sella is small, the tumour being either entirely suprasellar, or, if intrasellar, quite small.

Of females of the child-bearing period, over 70 per cent. sooner or later cease to menstruate, while others have scanty and irregular periods. Menstrual activity is affected less frequently in acidophil than in chromophobe adenoma. In Henderson's series 16 out of 66 acromegalic women of the child-bearing period continued to menstruate regularly for some time after their acromegaly had become obvious; in a few of them one or even two normal pregnancies occurred. In chromophobe adenoma amenorrhœa is almost invariably the first recognisable symptom of the disease and subsequent child-bearing is the greatest rarity.

After operation, or less commonly after intensive X ray treatment to the pituitary gland, the normal menses will sometimes return and normal pregnancies have occurred. In one of my cases a healthy child was born, although the mother had never menstruated after her tumour was removed eighteen months before the confinement (D. M. Stern, *Proc.*

* The prognosis of visual loss will be dealt with in a second article.

¹ No attempt is made here to consider epidermoid tumours (tumours of Rathke's pouch) or other tumours arising near the pituitary gland.

² O. Hirsch (Wiener klin. Woch., 1931, xlv., 932) has called this *benign acromegaly* to distinguish it from outspoken malignant acromegaly.

Roy. Soc. Med., 1934, xxvii. (Sect. Obst. and Gyn.), 79-80). In males sexual disturbance occurs perhaps less frequently than in females, but in practically all subjects with a large tumour there is partial or complete loss of potency and of sexual desire. Sexual function often improves after operation, but it is not possible at present to predict those cases in which improvement will occur.

Disturbance of Carbohydrate Metabolism

Patients with pituitary adenomas are subject to disturbance of carbohydrate metabolism. In chromophobe adenoma sugar tolerance is usually raised and the patient becomes fat. The obesity is rarely of such a degree as to require dieting, but when it is dietetic treatment is usually effective. With few exceptions acromegalics have a lowered sugar tolerance and diabetes occurs sooner or later in 25 per cent. of them. I have also seen it in a case of suprasellar cystic chromophobe adenoma. (Diabetes is also very common in association with basophil adenoma.) It may come on years after the onset of acromegaly, even after the visual symptoms of the disease have been successfully dealt with by operation, and it is never safe to predict that an acromegalic will not develop diabetes. In this connexion it may be said, however, that it is more likely to occur in patients with a family history of diabetes. Its onset appears to bear no relation to the size of the tumour, and it is of variable intensity. As a rule it responds fairly well to dieting and insulin, and is more easily controlled in this way after partial removal of the tumour than before. A few cases have been reported in which diabetes temporarily disappeared after removal of the tumour. All acromegalics should have expert guidance about their diet.

Headache and Other Subjective Discomforts

In acromegaly severe headache behind the eyes is likely to occur as the malady advances. The walls of the bony sella take part in the generalised bony thickening that is a characteristic of the disease and doubtless offer great resistance to increase in bulk of the tumour they enclose. It is not surprising that lachrymation, sometimes intense, usually accompanies the headache, probably produced by expansion of the tumour laterally and by partial obstruction of the cavernous sinuses. Sudden cessation of headaches suggests that the tumour has broken through the diaphragma sellæ and is extending upwards. Pain in the face, often unilateral and perhaps even simulating trigeminal neuralgia, may also occur. These symptoms can be partially relieved by irradiation of the pituitary region, and also by transphenoidal decompression of the sella. It may be that this operation should sometimes be undertaken for the relief of headache alone.

Acromegalics suffer also from discomfort in their hands and feet. Enlargement of the tongue may make speech difficult and may offer partial obstruction to breathing during sleep. Nasal catarrh also is common in advanced cases and most acromegalics suffer at some time or other from periods of great bodily weakness. These symptoms are not necessarily incapacitating and they are often improved by operation. Usually the discomforts lessen as the years pass.

Patients with chromophobe adenoma do not suffer from intense headache, doubtless for the reason that in them the bony sella is not thickened and expands or gives way as the tumour increases in size. But

they often have, as do acromegalics, periods of drowsiness when they feel an intense desire to give way to sleep in the day-time

HUGH CAIRNS, M.B. Adelaide, F.R.C.S. Eng.,
Surgeon to the Neurosurgical Department,
London Hospital.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. K. A. I. Mackenzie to *Victory* for R.N.B.; S. G. Rainsford to *President* for R.N. College, Greenwich; and A. G. Bee to *Drake* for R.N.B.

Surg. Lt.-Comdrs. L. J. Corbett to *Galatea*; and J. G. Holmes to *Pembroke* for R.N.B.

Surg. Lts. G. D. Wedd to *St. Vincent* and to *Amphion* on commg. for trials; and S. J. Wheeler to *Tamar* for R.N. Hospl., Hong-Kong.

ARMY MEDICAL SERVICES

The King has approved the following appointments:—

Major-Gen. T. S. Coates, O.B.E., late R.A.M.C., Col. J. Heatly-Spencer, O.B.E., late R.A.M.C., and Lieut.-Col. R. N. Chopra, C.I.E., I.M.S., to be Honorary Physicians to the King, in succession to Major-Gen. R. B. Ainsworth, C.B., D.S.O., O.B.E., and Major-Gen. P. H. Henderson, C.B., D.S.O., late R.A.M.C., and Major-Gen. Sir Robert McCarrison, C.I.E., I.M.S., who have retired.

Major-Gen. O. Ievers, D.S.O., late R.A.M.C., Col. E. W. C. Bradfield, C.I.E., O.B.E., Honorary Surgeon to the Viceroy of India, and Lieut.-Col. A. A. C. McNeill, I.M.S., to be Honorary Surgeons to the King, in succession to Major-Gen. J. F. Martin, C.B., C.M.G., C.B.E., late R.A.M.C., and Major-Gen. H. R. Nutt, late I.M.S., and Col. H. E. Stanger-Leathes, late I.M.S., who have retired.

Lieut.-Col. R. N. Chopra and Lieut.-Col. A. A. C. McNeill are promoted to the rank of Brevet Colonel on their appointment as Honorary Physician to the King and Honorary Surgeon to the King, respectively.

ROYAL ARMY MEDICAL CORPS

Short Service Commissions: Lts. (on prob.) restd. to the estab.: A. M. Pugh, J. H. Taylor, and G. C. Dansey-Browning.

A. R. O. Denton to be Lt. (on prob.).

Lt. (on prob.) G. G. Robertson resigns his commn.

REGULAR ARMY RESERVE OF OFFICERS

Lt.-Cols. C. T. Edmunds, D.S.O., and J. A. Anderson, and Majs. G. H. Stack and E. G. Antonisz, having attained the age limit of liability to recall, cease to belong to the Res. of Off.

ROYAL AIR FORCE

Wing Comdrs. P. T. Rutherford, O.B.E., to No. 1 Flying Training School, Leuchars, for duty as Medical Officer; and T. J. Thomas to No. 6 Flying Training School, Netheravon, for duty as Medical Officer.

INDIAN MEDICAL SERVICE

Majs. to be Lt.-Cols.: R. A. Logan and F. M. Kirwan. Maj.-Gen. T. G. F. Paterson, C.B., D.S.O., K.H.P., retires.

Indian Medical Department.—Capts. (Sen. Asst. Surgs.) to be Majs. (Sen. Asst. Surgs.): L. P. Gernon and R. H. Hughes.

DEATHS IN THE SERVICES

The death occurred at Cheltenham on Nov. 27th of Lieut.-Colonel WILLIAM KEITH HATCH, I.M.S., retired, who was born in 1854. He qualified M.B., C.M. Aberd., and M.R.C.S. Eng. in 1876, becoming a Fellow in 1887. After residence at a provincial hospital he went to India in November, 1877, as "Surgeon, Bombay Army." He became surgeon to the Jamsetji Jijibhoy Hospital and first professor of anatomy, then professor of surgery at the Grant Medical College. In 1897, when principal of the college, he reached the rank of Lieut.-Colonel, retiring six years later. Colonel Hatch held the Afghanistan medal 1880, which was issued in that campaign instead of the Indian medal.

SPECIAL ARTICLES

THE PHENOMENON OF TWORT-
d'HÉRELLE AND ITS SIGNIFICANCE

BY DR. E. WOLLMAN

ASSISTANT DIRECTOR, DEPARTMENT OF IMMUNOLOGY, PASTEUR
INSTITUTE, PARIS

It is just 20 years since Twort wrote the first description¹ of transmissible bacterial lysis. His work, however, published in the middle of the war passed unnoticed, and it was left for d'Hérelle² to draw the attention of inquirers to a remarkable phenomenon which has never ceased to enthrall them. Later work has determined the conditions, the processes, and to a certain extent the mechanism, of transmissible autolysis—a widespread phenomenon in the bacterial world. In spite of this its significance remains obscure and agreement is far from reached on the nature of the factors in play.

Singular it is that Twort had from the start foreseen the principal hypotheses which have since been put forward. We need not dwell on the views that it might be a new and lower form of life or that it was an invisible phase of the germ itself. Although revived by certain workers these views have not been accepted. It was otherwise with two explanations submitted by Twort, known as the parasitic and the diastasic theories, which have, with varying fortunes, prevailed in the history of transmissible lysis. Let us consider the arguments for each of these theories and see where they agree with the known facts.

1. The substances obtained from vaccinia pulp (for the staphylococcus, Twort) or from the intestinal contents (for the dysenteric group, d'Hérelle) impress on sensitive bacteria important modifications ending in conditions favourable to complete lysis.

2. The phenomenon is capable of being reproduced indefinitely—i.e., the active principles are regenerated during lysis.

3. The regeneration of the active principle, as well as the lysis, only occurs with living germs.

4. As shown by surface action and the results of dilution (d'Hérelle) the active principles have a discontinuous structure now known to be corpuscular.

5. These principles manifest a true autonomy in regard to the bacteria at the cost of which they develop (Bruynoghe, Wollman). This autonomy holds not only for the antigenic function of the active principles (Bordet and Ciuca) but also for their other characteristics.

THE PARASITIC THEORY

The persistence of certain characteristics, in the course of passage through different kinds of bacteria—e.g., antigenic control and sensibility to trypsin, Wollman and Mme. E. Wollman—suggests the existence of a power of assimilation. This, taken into account with the variability of other characteristics (virulence), leads to the conclusion that the active principles are living substances (d'Hérelle). The facts set out above appear to agree with the theory of a virus. The separate entity of the active principles, their autonomy, and their multiplication in the course of lysis are explained in this theory in the most natural way. This is d'Hérelle's particular theory which he has developed quite logically. The title of his first paper, on an Invisible Organism Antagonistic to the Dysentery Bacillus, is in itself a confession of faith. Since then d'Hérelle has continued to gather facts in support of his theory and many bacteriologists

have given their allegiance to it. To d'Hérelle the active agent is an ultra-virus parasitic on bacteria, the *Bacteriophagum intestinale* or *Protophagus bacteriophagus*. Lysis is the result of the action on bacteria of ferments secreted by the bacteriophage.

For some time this parasitic theory seemed to furnish a satisfactory explanation of the known facts. There were, indeed, a few difficulties, but these appeared to be on points of secondary importance. Thus the fact that the bacteriophages only multiplied in the presence of living bacteria was, in accordance with all that was known about filtrable viruses, but it was remarkable that their multiplication was dependent on that of the bacteria themselves (Bordet, Wollman.) Similarly how was it that bacteria, obligatory parasites, were found in media where sensitive bacteria failed to appear? Spontaneous bacteriophagy furnished a more serious difficulty. From the start Twort had noticed the apparently spontaneous appearance of transmissible lysis in pure cultures, and this fact encouraged him to discard the theory of a virus. d'Hérelle began by contesting the identity of Twort's phenomenon with bacteriophagy; the spontaneous cases of bacteriophagy, properly so-called, the supporters of the virus theory led by d'Hérelle explained by assuming the presence, either latent or occult, of pre-existing bacteriophages. Now the identity of the phenomena of Twort and d'Hérelle is well established, thanks chiefly due to the work of Gratia. On the other hand, it seems difficult to explain the numerous cases of spontaneous bacteriophagy, described by various workers, by a pre-existing contamination.

But the most serious difficulty confronting the parasitic theory is the existence of spontaneously lysogenic cultures. For those who maintain the theory of a virus it is a question of cultures being contaminated, but becoming resistant and living in symbiosis with the bacteriophage. Though not beyond the bounds of possibility such an explanation becomes extremely artificial when applied to all known cases of spontaneously lysogenic cultures. For instance F. M. Burnet, to whom we owe the most complete study of this question, has shown that all cultures of *B. paratyphosus* C, examined from whatever source (India, S. America, or Europe), were lysogenic and the bacteriophages from all these cultures were identical.

J. Bordet, studying a spontaneously lysogenic culture of *B. coli*, proved that there was neither lysis of sensitive germs nor regeneration of the active principle in decalcified medium. Now although the active principle was invariably absent during repeated passages on such a medium it reappeared when the lysogenic culture was transferred to ordinary media. It seems extremely difficult, if not impossible, to reconcile such facts with the theory of a virus. The same is true of observations I have recently made with a spontaneously lysogenic culture of *B. megatherium*.

The study of this spore-forming bacillus has a particular interest. Den Dooren de Jong³ has shown that cultures from spores which had been heated to 95°–100° C. remained lysogenic. The temperature necessary to destroy the bacteriophage produced by *B. megatherium* being 75° C. it would appear that the formation of bacteriophages de novo in cultures from heated spores and at the same time their endogenous origin was at last definitely established.

But this is not so. For Adant and Cowles have shown that spores of *B. subtilis*, "contaminated" with the corresponding bacteriophage, could be raised to a high temperature (100° C.) without the bacteriophage being destroyed. Similar results were obtained through the action of very high pressures.⁴ Neither the action of heat nor of pressure enables us to differentiate between cultures spontaneously lysogenic and those "contaminated" with bacteriophage.

Fortunately an observation of another order made on a lysogenic culture of *B. megatherium* can be brought in to refute the theory of symbiosis with an extrinsic bacteriophage. Whereas cultures on broth of Den Dooren's *megatherium* contain free bacteriophage (titre 10^{-3} – 10^{-4}), cultures on gelose do not. Lysis of such a culture by means of a drop of egg white (lysozyme of Fleming) is sufficient to cause the appearance of the bacteriophage; the active principle confined in the bacterial cells grown on gelose has been freed by the action of the lysozyme. It is an interesting fact, established by a number of titrations, that each bacterial element sets free only one bacteriophage corpuscle.⁵ Such numerical relationship between bacteria and bacteriophages would be difficult to explain by the theory of symbiosis. These findings, as well as others which cannot be enlarged on here, raise such difficulties for the parasitic theory that most bacteriologists have abandoned it. For instance, in an article devoted to bacteriophages published in July, 1933, Hoder⁶ came to the conclusion that "So many facts tell against the view held by d'Hérelle and his school that, without giving preference to any of the numerous theories formulated, it can be said with tolerable certainty that the bacteriophage is not a living being *sui generis*."

THE DIASTATIC THEORY

But if the active principles of transmissible lysis are not invisible living beings or viruses, what are they? The most striking manifestation of the phenomenon being the lysis of the bacteria attacked, Twort had conceived the idea of a particular ferment which was reformed in the course of its action. In spite of the difficulty of understanding such a process the diastatic theory has gained a favourable reception. Revived under various guises by numerous authors (Kabeshima, Gildemeister, Otto, Doerr, and to a certain extent by Bordet and his collaborators) it was at one time accepted by almost every bacteriologist; agreement was wellnigh universal that bacteriophages were soluble substances, lytic ferments, lysins, or autolysins.

Without stressing all the facts which militate against the identification of bacteriophages with lysins or autolysins—they are the same facts which have led to them being regarded as viruses—let it suffice to point out that these "lytic principles" are in fact devoid of any direct lytic action. Lysis properly so-called, as I have demonstrated,⁷ is the work of bacterial autolysins. On the other hand, research on the dimensions of the active elements in transmissible lysis carried out for several years at the institute for the Study of Colloids in Frankfurt, as well as at the Medical Research Institute in London, have assigned to these dimensions values on a very different scale from those of molecules of known ferments. From these researches it appears that the dimensions of the active corpuscles are constant for a given bacteriophage and vary for different bacteriophages, the extreme limits being, according to the method used (filtration or centrifugalisation) 8–12m μ and 75m μ (Elford and his fellow workers), or 20m μ

and 90m μ (Bechhold and Schlesinger).⁸ Summarising the results obtained in his laboratory Bechhold writes:—

"The dimensions of these corpuscles have been determined by an unexceptionable method and their form has been recognised; the elements themselves have been seen with the ultra-microscope and obtained in a pure state in quantities sufficient to be weighed."

All the fabric of ideas opposed to the parasitic theory, under the name of diastatic theories, is thus found to be baseless. And yet it might seem extraordinary to set up the parasitic theory as the solution of the problem of bacteriophage when we have just seen that Hoder and the majority of bacteriologists have definite grounds for rejecting it. In reality the quantitative data on dimensions of bacteriophages, as Bechhold has shown, permit us to discard the diastatic theory (taking the common acceptance of the word diastase), without authorising us at the same time to conclude that bacteriophage is a virus. Neither the corpuscular form of the active principles nor their dimensions prove anything in this respect. Only proof of their exogenous origin would be crucial and that proof is entirely lacking. Spontaneous bacteriophagy and especially lysogenic cultures make exogenous origin at least highly improbable.

THEORY OF HEREDITARY FACTORS

We are thus led to reject the parasitic and diastatic theories, for they are irreconcilable with the interpretation of the facts; on the one hand the corpuscular elements behaving in every way like living things, on the other the bacterial endogenous origin of these elements. Now these facts, impossible to reconcile with the classical theories, seem to find a simple explanation in the theory of hereditary factors which I have repeatedly enunciated.⁹ According to this theory the active principles of bacteriophages are particularly stable elements of cellular origin and act as a material basis for certain hereditary characters—hereditary factors in the Mendelian sense. This theory not only accounts for the facts which turn the scale now towards the virus theory, now towards the diastatic theory, but permits us to grasp facts which remain unexplained in either of these theories. The regeneration of bacteriophages is a function of the multiplication of the bacteria themselves, why there is a simple numerical relation between active corpuscles and lysogenic bacteria, why bacteriophages do not work on dead or quiescent germs. The terms bacteriophage and bacteriophagy, justified by the parasitic theory and by usage, then lose their significance and should be replaced respectively by lysogenic factors (Wollman) and transmissible autolysis (Bordet) or perhaps hereditary contagious autolysis (Wollman). I have shown that other processes of an infectious nature may have an analogous explanation, notably filtrable tumours and certain diseases of plants called mosaics.

Whatever may be the further extensions of this conception I have endeavoured here to show the new avenues which have been opened up by the study of the phenomenon of Twort-d'Hérelle. When the terms "infectious" and "microbial" became by degrees synonymous, the researches arising from the discoveries of Twort and of d'Hérelle have revealed the existence of infectious processes of non-microbial nature. In these processes certain characters (having a pathological form in the examples under discussion but not necessarily always pathological) are linked to a stable material basis and

in consequence can exist in an extracellular medium. Owing to this peculiarity these characters can be transmitted not only from mother-cell to daughter-cell (ordinary heredity) but also, through an external medium, from affected cell to normal cell (para-heredity).

The idea of a material basis for characters, which under the name of the theory of genes has proved so fertile in the study of normal and pathological heredity in the higher organisms, thus seems capable of extension to certain processes of an infectious nature which up to the present were usually attributed to genuine viruses.

A MODIFIED PLAN FOR A GENERAL HOSPITAL

CHANGES SUGGESTED AT THE NEW WESTMINSTER HOSPITAL

By E. ROCK CARLING, F.R.C.S. Eng.

SURGEON TO THE HOSPITAL

THE lay-out of a hospital in this country usually involves a horizontal division between visiting and resident patients. Although, generally speaking, each resident case has been an ambulatory, and will be so again on discharge, there is a gulf fixed between "in" and "out" which is symbolised by a separate entrance and emphasised by a change of doctor-in-charge. One consequence of this is that the "junior" staff, who may retain that status for twenty years, have care of patients only so long as they are fit to attend for treatment, and, with but minor exceptions—for the beds allotted to them in the smaller hospitals are usually comparatively few—lose sight of those patients as soon as their condition necessitates entrance to a ward.

No doubt the burden of out-patient work tells hardly upon senior men whose reputations have brought them big practice and many calls on their time for public duties. No doubt too the "clinic" exclusively in the wards is a convenient milieu for teaching and research, but it seems illogical from the point of view of service to the patient-community that there should be a break in the personnel. There seems, in fact, little reason nowadays for the continuance of this system other than the structural plan of hospital buildings. If the division of the hospital be made vertical rather than horizontal, complete effectiveness of the "firms" that have grown up as the unit of service in the hospital would be a natural and reasonable result. This, at any rate, is the idea behind the plan now under consideration for the new Westminster Hospital.

ADVANTAGES TO THE STAFF

There was a time when the distinction between the out-patient physician or surgeon and his senior

was a very definite one. There was a time when the relations between members of a staff were those of jealousy and distance, and when harmonious coöperation was often impossible. Such a state of affairs is now certainly rare, and the rule is that men work generously together, and if the work of a firm is concentrated there will at least be every opportunity for delegation, for sharing, and for mutual assistance, that must redound to the advantage of the patients.

On a surgical floor there will be two full units and certain accessory beds. Each firm will have an out-patient consulting-room and a theatre, but the latter will be paired so that a firm will be able, on its duty days, to make use of the consulting-room and theatre of his collateral unit, unless urgent work by the other firm interfere. The out-patient rooms, though on the same floor and adjacent to the wards, will be reached by a separate part of an encircling corridor.

The patients from the first moment of their arrival will be allotted to a firm or unit and will continue under the care of the senior or junior honorary medical officer, the same sister, registrar, and house officer to the last day of their attendance; and, again, if they have other need of the hospital, always finding someone who knows them and their past history ready to remember and welcome them. The same sister who has had charge of them in the ward will have charge of them as an out-patient on discharge and follow-up. The same sister who has charge of the male patients of a firm will have charge of the female. The permanent personnel of each firm will cover all its patients. The physicians, who make less use than the surgeons of their out-patient consulting-rooms on days other than those of the official visits, do not desire a separate out-patient department for each firm, and theirs will be common to the whole general medical department but will be in such proximity to their wards that the nursing may be directed by the sister of each firm at the appropriate time.

The specialists, at any rate the ophthalmic, otorhinological, dental, and dermatological, regard their clinics as essentially ambulatory, with beds attached rather than as wards in charge of a senior fed from an out-patient department in charge of his junior.

At the present time the actual attendances—apart from unofficial visits which nowadays are many—of the senior and his junior are at least seven a week between them, and if these be appropriately spaced, since availability of rooms and theatres is unrestricted, a fuller and more complete service to the patients will result without adding to the work of the honorary staff.

ADVANTAGES TO THE PATIENT

One consequence of this fuller or less intermittent service by the honorary staff will be to facilitate a solution of the problem of out-patient waiting. There will, of course, be a "front-surgery" on the ground floor, and adjacent to this what might be called a casualty clearing station in charge of whole-time officers of the status of registrars. Besides being at hand to superintend and advise the house officers in the "surgery," their job will be to sort newcomers for their appropriate units, and to select the "teaching" cases of the day, and with an out-patient clientele such as that found at Westminster it will be possible to arrange appointment-times for a great many cases. To work such appointment-bookings smoothly there will be an almoner on each floor, in whose care all the patients of two units will find themselves. The limitation of her

work to those units will, it is believed, also permit closer relations with the general practitioners by simplifying inquiry and communication.

The continuity of nursing service that will follow upon bringing the out-patient department into close contact with the ward should benefit the patient substantially, and there are, moreover, advantages in having a nurse's training supervised in both departments by one sister. It is unlikely that the scheme will necessitate any increase of nursing staff.

It might seem at first sight that to have separate out-patient departments must involve increased capital expenditure and more expensive upkeep; but the more the details of structure are studied the less serious does this point become. The waiting space though scattered is no larger. The rooms of those specialists who require increasingly complicated apparatus are, in any case, unsuitable for use by other departments, even when unoccupied by those specialists. The out-patient rooms of the gynaecologist and obstetricians, now that there are ante- and post-natal clinics, children's welfare, and other special clinics in addition to the regular out-patient days, are pretty continuously occupied. The rooms of the surgical firms will certainly be frequently, if not always, in use, for there are many patients who attend after discharge for periodic injections, or for plasters, for dressings, and so on.

The lift service will be an additional expense, but it seems likely that economies will be effected in other directions, and if the service rendered be more efficient, the saving of time itself will be saving of money.

THE PROBLEM OF CANCER

RETROSPECT AND PROSPECT

At the beginning of October Dr. W. E. Gye succeeded Dr. J. A. Murray, F.R.S., as director of the Imperial Cancer Research Fund. His contribution to the thirty-third annual report, presented last Wednesday, is a survey of the changes in outlook on cancer since 1902 when the Fund was established. This survey is of more than ordinary interest to the general medical reader, and we make no apology for reproducing much of it in Dr. Gye's words.*

"A DISEASE OF CIVILISED MAN"

In 1902, he says, extreme confusion and pessimism on the subject prevailed in the medical profession. There was a firm belief, amounting to a dogma, that cancer was a disease limited to man and that it occurred only in civilised communities, where it was increasing at a terrifying rate. Cancer families, cancer houses, and cancer villages were believed to exist. The causative influence of geological formation, of soil, of climate, of diet, of dwelling near trees or near rivers, was discussed. Many clinicians believed cancer to be an infectious and even a contagious disease. "Cancer germs" were isolated, or demonstrated in malignant cells by special staining methods. The destruction of bedclothes and other materials which had come in contact with cancer patients was often demanded.

The morbid anatomists, however, who had done fundamental work in classifying the numerous and different types of malignant new growths and who found it difficult to reconcile the morphological appearances of a cancerous growth with those of

known processes of infection, regarded cancer as a cellular disease and propounded a number of hypotheses to explain its origin, of which only one—the Cohnheim theory of embryonic rests—has survived as a possible explanation for certain rare malignant conditions. The question whether the growth of a malignant tumour is brought about by transforming the surrounding normal tissues into cancerous tissues or whether solely by multiplication of cells already malignant was a matter for discussion and controversy. Even the fact that cancer can be cured by operation at an early stage was by no means generally accepted.

An argument advanced to support the dictum that cancer is a disease of civilisation was the alleged freedom from the disease of lower animals. It is true that veterinary surgeons had described its occurrence in dogs and horses, but the evidence was either ignored or was met by the assertion that the features of the disease did not correspond with those in man, or, alternatively, that contact with man was responsible. It is difficult now to recreate in imagination the atmosphere of uncertainty which led to such an attitude. But it must be remembered that thirty years ago bacteriology had progressed far in its triumphant career, and that many diseases had been found to be transmissible to animals by inoculating into them morbid material from human patients. Attempts had frequently been made to transmit cancer from man to various species of animals, but always without success; and it was therefore concluded by analogy that animals are resistant to cancer. Hanau's observation that a rat tumour can be transmitted to other rats by inoculating pieces of the living tissue was ignored, and Morau's confirmation of it was no more favourably received. Even Jensen's subsequent demonstration that inoculated cancer arises from the actual cells which have been introduced and not through infection of the cells of the new host might have been unrecognised if it had not opportunely coincided with the establishment of the Imperial Cancer Research Fund, which under Dr. E. F. Bashford's direction was undertaking a systematic study of the incidence of cancer in human beings and animals. This study soon showed that the disease could be found throughout the vertebrate kingdom, wherever it was looked for properly. The fact that in all vertebrates animal cells can undergo the malignant transformation and that the resultant malignant cells possess everywhere the same fundamental properties is the foundation on which the experimental investigation of cancer, as it exists to-day, is built. Of the diseases which can be produced experimentally few, if any, simulate the normal human disease so closely as cancer.

This investigation emphasised the essential unity of the phenomenon of malignancy. It indicated that the process which takes place when a normal cell becomes malignant is essentially the same in whatever species or whatever organ it occurs. From another point of view, however, it was possible, and indeed necessary, to regard cancer as a multiplicity of diseases. Cancer is a disease which may appear in almost any organ or tissue. While in animals there were found to be certain sites of predilection in which cancer occurred with exceptional frequency and which were different in the various species, even in closely related species, of animals, in man cancer is found more evenly distributed over the various organs or tissues. In man this organ incidence shows considerable variation in the two sexes and also in different peoples and races. Here, therefore,

* The complete report is obtainable from the offices of the Fund, 8, Queen-square, London, W.C.1.

the further question arises: "Why does cancer arise in this or that particular organ?"

The investigation of aetiological problems of cancer in man is based mainly on statistical data. The opinion, formerly prevailing, that its incidence was rapidly increasing was based on the crude figures representing the total mortality of cancer. Following an argument previously developed by King and Newsholme, Bashford analysed the cancer mortality statistics with reference to the different organs, considering separately the accessible sites in which diagnosis was easy and the inaccessible sites in which diagnosis was difficult. He also induced the Registrar-General to publish the figures in a table classified according to Sex, Age, and Parts Affected, and it proved possible to show that the recorded increase in cancer mortality fell largely though not entirely on inaccessible sites where it is diagnosed with increasing ease. These statistical inquiries demonstrated that cancer is *not* increasing at an alarming rate in civilised communities, or appearing (as was asserted) at earlier ages. Similarly it was shown in other investigations that the disease is found among savages as well as among civilised peoples, and in animals both wild and domesticated, carnivorous and herbivorous.

THE NATURE OF MALIGNANT CHANGE

Side by side with the general and comparative study of the disease a close examination of the phenomenon of transplantation was made by Bashford and Murray. It was found, as Jensen had already shown, that when a fragment of cancer tissue is grafted the tumour which forms is derived from the living malignant cells inoculated; there is clear evidence, at least with carcinomas, that the normal tissues of the host are not "infected"—i.e., made malignant by the inoculum. Also, it was confirmed that transplantation is successful only within the species from which the tumour is derived. A mouse tumour will not grow in a rabbit, for example, or vice versa. The failure to transmit human cancers to the lower animals now became comprehensible. It was shown, further, that the propagation of a mouse cancer in mice can be carried on indefinitely; the malignant cells live and multiply in an unlimited number of generations of normal mice.

Clear deductions may be drawn from this experience, which are important in several respects, theoretical and practical. It follows in the first place that the *primum movens* of the disease is in the cancer cell itself; among other points it is clear that successive generations of normal mice are unable to affect the malignant qualities of the transplanted cells. The practical importance of these observations lies in the fact that most "cancer cures" are based on an assumption that tumours arise and grow because of some constitutional defect in the body of the patient. It has been assumed, for example, that cancers progress because some glandular structure—such as the pituitary or the parathyroid—is discharging inadequately a function which it is supposed to possess, of controlling "growth." There is almost always a confusion in the terms employed in the statement of the theory, but the practice is uniform—the preparation of extracts of the normal gland taken from a large animal and the injection of the extracts into patients in the hope of bringing about a cure. Such treatment is unsound in theory and valueless in practice.

The demonstration by experiment of the local origin of tumours, and the proof that the disease is confined to the affected cells and is not spread by

contact and infection within the body, confirmed the conclusions reached by the morbid anatomists during the later decades of the nineteenth century and justified the operative practices of the best surgeons, who aimed at the complete removal of a tumour as early as possible. These results of experimental cancer research consolidated what had hitherto been a tentative, unstable theory; it gave a true theory of the nature of cancer which had a direct effect on surgical procedures.

But if practical medicine derived much benefit from the early results of experimental study, their effect on the theoretical conception of intracellular change was not perhaps so happy. The absence of all microscopical evidence of infection in cancers; the proof that tumours grow out of their own resources, the malignant cell using the body foodstuffs to grow and divide and form the tumour; the fact that tumours of mice could not be propagated by any means except the grafting of living cells; the species specificity of tumours—all these facts, and many others less definite, led investigators to an unshakable conclusion that the explanation of malignancy lies in some alteration in the cell itself, in virtue of which the malignant proliferation is an automatic process, independent of the presence of a continuously acting provocative agent. It is in this sense that tumours are sometimes said to be "causeless." In Ewing's words "the secret of malignancy seems still to remain enshrouded in the obscurities of intracellular life, where it will probably long remain." Nevertheless when all the facts which have been accumulated are taken into consideration we have no need to believe that the theoretical problems of cancer are insoluble.

It is an encouragement that since the Great War interest in cancer research has widened. It is no longer confined to the microscopic study of the cancerised cell and of its relationships to normal cells in the body. The attack has been extended to the very onset of the disease. In 1902 Bashford drew up a "draft scheme for inquiry into the nature, cause, prevention, and treatment of cancer" (published in 1908 as an appendix to the Fund's third scientific report) in which the possibility of producing cancer experimentally is discussed in connexion with "sweeps" cancer" and "petroleum cancer." He suggested that "a systematic study of the effects of persistent irritation of different epithelial surfaces in different species of animals might be found to have important bearings." To the Japanese investigators Yamagiwa and Itchikawa belongs the honour of demonstrating, in 1915, that cancer can be produced in this way by painting an animal with tar. This has proved the starting-point of innumerable investigations which have culminated in the preparation by Prof. Kiennaway and his collaborators of pure chemical substances with carcinogenic properties. Some of these substances are related chemically to the sterols which are normal constituents of the body. The importance of these investigations is too evident to need any comment.

THE PROBLEM TO-DAY

It is now quite clear that two aspects of the cancer problem must be sharply defined: first that which deals with the conversion of a normal cell into a malignant cell (by tar, pure chemical compounds, parasitic worms, radiant heat, X rays, &c.); and, secondly, that which deals with the properties of the malignant cell itself, seeking an explanation of its power to proliferate indefinitely.

In 1911 Peyton Rous of the Rockefeller Institute, New York, described a spindle-celled sarcoma of the domestic fowl which could be propagated not only with grafts of living cells but also by means of cell-free filtrates, and since then a score or more of filtrable avian tumours of diverse structure have been described. Each has the same remarkable property of filtrability, and the agents possess the same extreme specificity shown by the filtrates of the tumour first described by Rous. There now exists, therefore, a group of tumours caused by intracellular agents which have properties indistinguishable from the viruses.

The first reaction of pathologists to these filtrable tumours was a denial of their neoplastic nature, or, alternatively, an assertion that if they are neoplastic then these tumours are a disease of birds sui generis imitating cancers of mammals, but not of the same essential nature. But Rous and his collaborators demonstrated conclusively that if these tumours are not true new growths then the task of describing the characters of new growths must be begun again; for these growths of fowls exhibit all the properties which are accepted by competent students as characteristic of true tumours. Briefly, it may be said that apart from the property of non-cellular transmission there is no clinical, morphological, or biological difference between avian and mammalian tumours. Even this criterion of filtrability cannot be claimed as absolute. There are malignant fowl tumours, such as the spindle-celled sarcoma first described by Rous, which though as a rule easily filtrable, may pass into a state in which they do not yield active filtrates. The tumours occasionally lose growth energy and become comparatively benign; when in this state it is frequently impossible to transmit the growths by any means except by grafts of living tissue. Moreover, the recent discovery of a filtrable papilloma of the cotton-tail rabbit by Dr. R. E. Shope has broken the apparently absolute difference in respect of filtrability between tumours of mammals and tumours of birds. One of the pressing tasks of cancer research is the study of tumours of a greater variety of species of animals.

The two aspects of the problem, to which reference has been made, have lately been drawn together by experiments carried out by Prof. McIntosh at the Middlesex Hospital. Tumours were started in fowls by injecting tar subcutaneously, and the tumours thus obtained were transplanted into normal fowls. It was found for three of such tumours that it was possible, once the difficulties of propagation had been overcome, to transmit the growths by means of cell-free filtrates. If these experiments can be confirmed, the part played by tar in cancer causation is different in kind from the part played by the agent which passes through a filter candle and which can be obtained again and again from each successive generation of tumour.

Dr. Gye concludes: "This account of the systematic investigation of cancer which began in an atmosphere of ignorance and pessimism thirty odd years ago, and which has since developed into an independent discipline of medical research that is being carried on vigorously in every civilised country, is necessarily brief and incomplete. . . . But it can be said without fear of contradiction that the knowledge of the disease gained in this short time is more extensive than that of most other chronic diseases and has profoundly influenced its diagnosis and treatment. Cancer has ceased to be an unaccountable mystery, and we need no longer fear that its solution surpasses the wit of man."

MEDICINE AND THE LAW

Unregistered Practitioner Fined for Treatment of Venereal Disease

For good and sufficient reasons Parliament in 1917 prohibited the treatment of venereal disease by any person other than a registered practitioner. For infringing this statutory restriction Mr. Robert Vivian Storer was fined £100 with 20 guineas costs at Marlborough-street police-court last week. The summonses alleged that he, not being a duly qualified medical practitioner, did treat two patients for reward, that he prescribed a remedy, and by advertisement offered to treat patients for venereal disease. Mr. Lawson Walton, appearing for the Director of Public Prosecutions, explained that in May last, Mr. Storer, who had practised for many years and held the degrees of M.R.C.S. Eng. and L.R.C.P. Lond., was found guilty after inquiry by the General Medical Council of infamous conduct in having advertised a clinic at his registered address; his name had then been erased from the Medical Register. In the following July an advertisement appeared in a daily paper of the Cavendish Institute of Medical Research, 9a, Cavendish-square; it was described as a diagnostic clinic for venereal and allied infections, including determination of cure and tests of latency. Two men, who answered the advertisement, gave evidence for the prosecution last week. One called by appointment and saw Mr. Storer in a room fitted up as a dispensary. He was examined and was told he was suffering from the disease and could be cured in three months; the fee would be 100 guineas. The patient said this was more than he could afford; Mr. Storer replied that the only alternative was to go to a public clinic for nothing where the treatment would take 12 months and be very unsatisfactory. Asked about a reduced fee, Mr. Storer said he did not make a practice of reducing fees; he was full up with work, and he produced his appointment book to prove the fact. Finally he agreed to accept 40 guineas—25 guineas down and 30s. a week during treatment; but he said the treatment would be less satisfactory and would take longer. Finding the patient undecided, he offered him a treatment on the spot for 3 guineas. The patient had not the money, and was told he must send a cheque immediately. Thinking the whole matter very unprofessional, the patient left the house. In the case of the second witness, Mr. Storer was said to have expressed surprise, after showing the result of the test, that another doctor had passed the patient as free. Mr. Storer offered to cure him for 100 guineas; when the patient was shocked at the amount of the fee, he agreed to accept 25 guineas in advance and 25 for each month of treatment; his consultation fee, he said, was 5 guineas, and this, with the 25 guineas payment in advance, was paid by the patient by cheque. The patient took several treatments but afterwards got other advice and went no more to the clinic. The defence set up by Mr. Storer as regards this second patient was that the man never suffered from venereal disease, and therefore he himself could not be charged with having treated him for it. The magistrate observed that the question whether the patient did in fact suffer from the disease or not did not in his opinion arise.

Mr. Storer, giving evidence on his own behalf, said he founded the Cavendish Institute of Medical Research. He was still a qualified man and a physician and surgeon. He came from Australia at the

age of 21 to qualify as a doctor. He also took a 2½ years' post-graduate course in Vienna and London in the study of venereal disease. He then went back and practised as a specialist in Australia. He had attended medical congresses and had been associated with research as to venereal disease; he had published a book called "Sex and Disease" which had been favourably received by almost every medical journal; his research work had cost him £20,000. He had discovered that other symptoms followed the disease itself. In January, 1934, he came to London and published advertisements of the Cavendish Institute in the medical papers as a free diagnostic clinic. In December, 1934, he called at the office of the General Medical Council with a contemplated partner to ascertain if these advertisements would form any ground of complaint professionally. He never received any ruling from the G.M.C. and, having withdrawn the advertisements for two months, he afterwards reinserted them. In May last he was summoned before the G.M.C. and, thinking he was at last to receive the ruling for which he had asked, he made no defence. His name was struck off the Register; he then amended his advertisements, realising that, as regards venereal disease, his services could only be available as a diagnostician. He said that, since he had been struck off the Register, he had not treated a case of venereal disease, and indeed had sent many such cases to the doctors and staffs of public clinics in London.

Mr. Eustace Fulton argued on the defendant's behalf that diagnosis and treatment were not the same thing. The magistrate thought that, for the purpose of the statute, diagnosis was undoubtedly part of treatment. He held that the case was proved, and he accepted the evidence of the two patients in preference to that of Mr. Storer. It had been said that the defendant was a man of great skill and distinction; in the magistrate's view this statement could have no bearing on the case; it was no answer for the defendant to say "although I am technically disqualified because of advertising, I am a very fine doctor in this particular branch of doctoring." The defence intimated that there would be an appeal on the point of law—presumably as to diagnosis forming no part of treatment. On the facts accepted by the magistrate, however, treatment under Section 1 of the Act and the advertisement under Section 2 of an offer of treatment would seem to have been proved. If a man can be struck off the Register for professional misconduct and can then defy the 1917 Act by resuming practice in the treatment of venereal disease for 100-guinea fees, it is not surprising that the court should think fit to impose a substantial fine.

A Vegetarian's Diet

In the county court at Weston-super-Mare a vegetarian successfully disputed a claim from a lodging-house keeper. He had booked his rooms for a fortnight, stipulating that he and his family were vegetarians and must have vegetarian diet. He vacated the rooms after a week because the plaintiff had not given him reasonable service. The house had been overcrowded, other lodgers sleeping in the breakfast-room and in the bathroom; and the diet had been unsatisfactory, the salad being drowned in vinegar, and the potatoes hard and inedible. The judge held that, in respect both of the overcrowding and of the diet, the plaintiff had failed to give reasonable service. The defendant had therefore been justified in refusing to stay for the second week.

The keeper of a lodging-house may not be obliged to cater for everyone who insists on a special diet; if he undertakes to supply a vegetarian diet, he must reasonably keep his word.

FATS IN THE BLOOD

Mr. C. P. Stewart, Ph.D., in a paper read to the Edinburgh Pathological Club last week, summarised investigations he has been making into the fat content of blood. Estimation of the various constituents of normal human blood (including glycerol by a newly devised method) indicates that as much as 20 per cent. of the total fatty acid found may be present in the form of simple glycerides. In the blood of diabetics the simple glycerides are generally increased, and this increase is the main factor in the very high total fat content often encountered. In pernicious anaemia the quantity of lipid phosphorus of the whole blood is generally reduced; but Mr. Stewart believes this reduction to be without significance, for he has found that the blood plasma and the corpuscles both contain a normal concentration of lipid phosphorus. The apparent anomaly is explained simply by the lack of red cells in this condition, for the concentration of lipid phosphorus is twice as great in the cells as in the plasma.

EDINBURGH ROYAL INFIRMARY

Difficulties facing the Royal Infirmary were referred to at a meeting of the league of subscribers in Edinburgh last week. The sum of £150,000 is still required to complete the extension scheme, and the infirmary's adoption of the management of the new maternity hospital will add greatly to the annual expenditure. Members of the league of subscribers contribute a small sum weekly, but are not entitled to any special consideration in view of this, and some of them have had to be transferred to municipal hospitals for treatment because of the length of the waiting-list of the Royal Infirmary. In view of their regular contributions resentment was expressed that these people should have to pay for treatment at the municipal hospitals, and further have to submit to a means test in order that the amount they should pay might be determined. This was one of the arguments used in a plea for closer coöperation between the voluntary and the municipal hospitals.

IRELAND

(FROM OUR OWN CORRESPONDENT)

FUNDS FOR MEDICAL RESEARCH

For the past two or three years a joint committee, set up on the initiative of the Royal Academy of Medicine in Ireland, and consisting of representatives of the several licensing bodies and of the Associated Hospitals Committee which promotes the sweepstakes and of the Academy itself, has been working at the formulation of a scheme for medical research in the hope of inducing the Minister for Local Government and Public Health to provide adequate funds from the monies at his disposal from the hospital sweepstakes. It was proposed to establish a research council consisting of representatives of the licensing bodies, the Academy, and the hospitals, and the Government, and the Minister

THE LANCET]

was asked to provide funds to the amount of £10,000 or £12,000 a year, the distribution to be in the hands of the council. The Hospitals Commission, the body appointed to advise the Minister as to the distribution of the sweepstakes funds, recommended the proposal to the Minister some thirteen months ago, and the long delay in the Minister's department has given rise to comment. It is now officially announced, however, that the Minister has approved of the formation of a council of nine, comprising one representative from each of the following, with an independent chairman: the senate of the National University of Ireland; Trinity College, Dublin; University College, Dublin; the Royal College, Cork; University College, Galway; the Royal College of Physicians in Ireland; the Royal Academy of Medicine in Ireland. To enable the project to be initiated, the Minister is willing to allocate a sum of a maximum amount of £10,000 for the first year's working. It is understood that the council will meet to take steps to become incorporated, and will consider and formulate proposals for the prosecution of medical research. The Minister has the appointment of a chairman under consideration.

It is not as yet clear how far the proposals approved by the Minister differ from the scheme put forward by the joint committee and recommended by the Hospitals Commission. Some changes which may cause disquietude have been made in the constitution of the council, the body approved by the Minister being smaller and less representative than that recommended to him. More important, however, than the constitution of the council will be its powers, with regard to which the official statement is vague. If its powers are to be limited to "considering and formulating proposals for the prosecution of medical research" and decisions are to rest with some other authority, much disappointment will be felt. It was an essential part of the joint committee's scheme that decisions as to the research to be carried out and the distribution of such funds as the Minister might provide should be in the hands of the Research Council.

BUDAPEST

(FROM OUR OWN CORRESPONDENT)

TERCENTENARY OF BUDAPEST UNIVERSITY

The University of Budapest was founded in 1635 by Peter Pázmány, Roman Catholic archbishop of Esztergom, and delegates from 130 universities from all parts of the world attended the anniversary of its foundation recently celebrated here with great magnificence. At the time of the Turkish invasion the older universities at Pecs, Pozony, Bratislava, and Buda were destroyed, and in his inaugural address Géza Kornis, rector magnificus, paid tribute to the love of culture which had led Hungary to found this university at one of the most troublous times of her history. He also emphasised the important part Hungary had played in preserving Western civilisation from the invaders; "Hungary stopped the influx of Tartars and Turks," he said; "and if the Magyars had not fought this battle, to-day the Koran would be taught at Oxford." He also spoke of the famous men who had worked at the University and in the medical faculty mentioned particularly János Balas and Ignaz Semmelweis. An exhibition was held in the library which illustrated the development of the University in

photographs, and included many interesting documents relating to its foundation. Among official records the original matriculation books from 1635 were on view.

A prominent feature of the ceremonies was the constitution of the Society of Doctors Sub-Auspiciis Regis. The membership of this society is limited to the very small number of graduates who have passed every examination in their university career with distinction. To such graduates from 1895 onwards Francis-Joseph, as King of Hungary, presented a valuable gold ring. After the end of the late war no awards were made, but in 1923 Nicholas Horthy, as Regent, gave leave for their continuation, granting an iron ring with the inscription "sub-auspiciis gubernatoris." During the 40 years since the award was started it has been given to 147 candidates, and the aims of the new society are to unite its members in reverence and love of their alma mater, to contribute to its maintenance and development, and to assist the university students. Dr. Tibor Verebélyi, professor of operative clinical surgery, received the ring in 1900 and his son of the same name gains it this year; while Prof. Nékám, president of the recent international congress of dermatology, has two sons who have received the honour, in 1928 and 1934.

In connexion with the celebrations the foundation-stone of the University tuberculosis clinic was laid by Bálint Homan, minister of culture. Other stones were laid by the dean and the rector of the University.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 23RD, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2860; diphtheria, 1434; enteric fever, 27; acute pneumonia (primary or influenzal), 845; puerperal fever, 36; puerperal pyrexia, 124; cerebro-spinal fever, 13; acute poliomyelitis, 10; acute polio-encephalitis, 2; encephalitis lethargica, 65; 10; dysentery, 29; ophthalmia neonatorum, 65. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Nov. 29th was 3305, which included: Scarlet fever, 1198; diphtheria, 1262; measles, 85; whooping-cough, 240; puerperal fever, 19 mothers (plus 10 babies); encephalitis lethargica, 281; poliomyelitis, 8. At St. Margaret's Hospital there were 14 babies (plus 3 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 28 (0) from measles, 6 (0) from scarlet fever, 9 (2) from whooping-cough, 32 (6) from diphtheria, 48 (16) from diarrhoea and enteritis under two years, and 53 (12) from influenza. The figures in parentheses are those for London itself.

Manchester reported 12 deaths from measles, Liverpool 4, Bolton and St. Helens each 2, no other great town more than 1. Deaths from diphtheria were reported from 20 great towns: 4 from Sheffield, 3 each from Birmingham and West Bromwich. The mortality from influenza is scattered over 21 great towns, Manchester, Newcastle-on-Tyne, and Sheffield each reporting 3, no other great town more than 2. There were 4 deaths from whooping-cough at Liverpool.

The number of stillbirths notified during the week was 269 (corresponding to a rate of 44 per 1000 total births), including 36 in London.

VOLUNTARY HOSPITALS OF YORKSHIRE.—The Yorkshire Voluntary Hospitals' committee in their thirteenth annual report record that grants to hospitals amounting to £2611 and £7445 in other contributions have been paid direct to hospitals.

OBITUARY

ERNEST WILLIAM WHITE, C.B.E., M.B. Lond.

EMERITUS PROFESSOR OF PSYCHOLOGICAL MEDICINE,
KING'S COLLEGE, LONDON

THE veteran specialist in mental disease, Prof. E. W. White, died at Betley House, Shrewsbury, on Nov. 28th, at the age of 84. He had outlived most of such contemporaries as worked in his special field.

Ernest William White was the son of Richard White of Norwich, and was educated at the Bury Grammar School, the first of the grammar schools founded by Edward VI., and ranking seventy years ago as a prominent public school. He received his

ERNEST WHITE

[Photograph by Elliot & Fry]

medical training at King's College Hospital and the Norfolk and Norwich Hospital and at King's was a highly distinguished student, winning several scholarships and medals, among others the Warneford clinical scholarship. He qualified in 1872 as M.R.C.S. Eng., and proceeded to the London degree, where at the first M.B. examination he secured the gold medal in anatomy as well as taking honours in all the other subjects.

After house appointments and a prosectorship of anatomy at the Royal College of Surgeons of England, he commenced his successful career in psychiatric medicine with an appointment as assistant medical officer to the Kent County Asylum, Chartham. This post he held for nine years, when he became resident physician-superintendent at the City of London Asylum at Dartford, and held this appointment for eight years. During this time he successfully completed his M.B. course, obtaining the M.B. Lond. in 1883, graduating in the first division, and in the following year obtained the diploma of M.R.C.P. Lond. In 1890, in succession to Prof. Edgar Sheppard, he became professor of psychological medicine at King's College, a post which he held for 20 years, when he was elected emeritus professor.

Prof. White had been an enthusiastic volunteer and acting surgeon in connexion with the Royal West Kent Regiment. Shortly after the outbreak of the European war he was appointed consultant in mental diseases to the Western Command, and later consultant to the War Office with the rank of lieutenant-colonel. He was appointed O.B.E. in 1919, and in 1920 obtained the C.B.E. (mil.).

Prof. White, who had been president of the Royal Medico-Psychological Association, made many practical contributions to the literature of his subject. To the King's College Hospital Reports he contributed papers on psychological medicine in relation to the general practitioner, and on puerperal insanity. In the *Journal of Mental Science* he published papers on epilepsy connected with insanity, on the remodeling of old asylums, and on the care and treatment of persons of unsound mind in private houses and

nursing-homes. Papers from his pen appeared in *The Lancet* on the association of insanity with myxœdema and on lunacy law reform, while in the *British Medical Journal* he summarised his war experiences with the Western Command in a paper on shell-shock and neurasthenia.

After his retirement from the City of London Mental Hospital he became a part proprietor of "Fenstanton," Christchurch-road, Streatham, in association with the late Dr. Henry Rayner and Dr. Outterson Wood, and continued his interest to the present time in this licensed home for 30 female mental patients. Latterly he lived at Shrewsbury and only occasionally visited London. But those of his contemporaries who remain and many of his old students remember him as a sound exponent of his subject.

ROBERT HERBERT MILLS-ROBERTS, C.M.G.,
F.R.C.S. Edin.

Robert Herbert Mills-Roberts, who died in a nursing-home at Bournemouth on Nov. 27th, was the son of Robert Roberts, J.P. of Plas Meinl, Festiniog, and was born in 1862. He received his medical education at St. Thomas's Hospital. He took the double English qualification in 1887, and in 1893 obtained the diploma of F.R.C.S. Edin. He held numerous residential appointments, being house officer at the Stroud General Hospital, the Birmingham General Hospital, the Leicester Infirmary, and the Royal United Hospital, Bath, and then went into practice in Wales as surgeon to the Dinorwic Hospital and quarries, Llanberis, a post which he held until the outbreak of the European war. When he joined up in 1914 the life of a military surgeon was not new to him as he had served with the Welsh Hospital in the South African war, when he was mentioned in dispatches and received a medal with clasps and the C.M.G. In the European war he did important service. Going out with the British Expeditionary Force he served throughout the whole period of hostilities, being at first second in command of the 6th Royal Welsh Fusiliers, and later officer commanding 131st Field Ambulance and the 41st Stationary Hospital with the rank of lieutenant-colonel. At the conclusion of hostilities he was appointed deputy commissioner, medical service, North Wales and Shropshire (Ministry of Pensions).

Colonel Mills-Roberts was widely known in the district where he resided, as his father had done before him, while in athletic circles half a century ago he was famous as a goalkeeper under Association rules. He was then a Welsh international player, and in 1888 kept goal for the Preston North End Club, when the club won the championship without having a goal scored against them.

REBUILDING OF QUEEN CHARLOTTE'S.—The Duke of York on Nov. 26th presided at a dinner held at the Grocers' Hall in aid of a fund for the rebuilding of Queen Charlotte's Maternity Hospital, London, which, when completed, will be the largest maternity hospital in the Empire. Building is to be started early next year and it is hoped to provide 230 beds with both public and private wards at a cost of £300,000. The first section, comprising 75 beds, will cost £80,000, and already a large proportion of this has been given or promised. The scheme includes a home for nurses and a hostel for students.

PANEL AND CONTRACT PRACTICE

The New Act

IN about a month's time approved societies will be busy issuing some 18 million health insurance contribution cards, for the first half-year of 1936, to their members. The Minister of Health has arranged for a special leaflet to be issued with each contribution card explaining the provisions made in the 1935 Act for continuing the insurance of persons who fall out of employment. In future, so long as an insured person remains entitled to sickness and disablement benefits, no reduction will be made in the rates of those benefits because he has been unemployed, provided that proof of unemployment is given to his approved society in good time, ordinarily by means of a franked contribution card. A person who had been continuously insured for ten years at the commencement of his "free insurance period" (which lasts from eighteen months to two years from cessation of employment) will have his insurance extended from year to year provided he continues to prove his genuine unemployment—again by means of franks. During these "extended insurance periods" he will remain a member of his society and will continue to be insured so far as pensions are concerned. He will lose his sickness and disablement benefits, but will retain medical, maternity, and any additional treatment benefits provided by his society. Many insured persons who had lost their title to medical benefit by reason of prolonged unemployment, under the 1932 Act, will be restored to benefit, but surely the super-optimist is the insurance practitioner who, assuming that every person who had ceased to be insured during the past three years would be reinstated in benefit, rang up his insurance committee to ask whether the limit of 2500 would be suspended so as to allow all his old patients to be restored to his list.

Certificates and Their Uses

There is an increasing tendency on the part of employers to inform their staffs that they may submit for inspection forms Med. 40 when absent from work owing to illness. The Manchester medical (and panel) committee recently took up the impropriety of a letter addressed by a local firm to their employees who are absent from work for some days owing to illness, requesting the employee to allow the firm to see the form Med. 40 obtained from the doctor. The panel committee requested the insurance committee to direct the firm's attention to the fact that insurance practitioners are required to issue medical certificates to their patients free of charge only for the purposes of National Health Insurance. The insurance committee decided to receive the panel committee's letter.

The "House Doctor"

The London panel committee have also been having a little trouble with a firm of employers. An insurance doctor had on his list a number, about one hundred, of the employees of a firm who resided in a hostel. The doctor sold his practice to another practitioner who learnt that the firm were exhibiting a notice in the hostel to the effect that in consequence of the resignation of Dr. A. it had been decided to transfer to Dr. C. (not the successor to Dr. A.'s practice), and accordingly it would be necessary for all medical cards to be handed in to the steward's office duly completed in part B. The successor

endeavoured to persuade the firm to withdraw the notice, but the directors could not see their way to do so, whereupon the assistance of the local medical and panel committee was invoked. The committee got in touch with Dr. C. who stated that he had never visited the hostel and was unaware of the exhibition of the notice; he wrote to the firm asking that the notice should be removed and this was done. A representative of the firm stated that there was no compulsion upon any of their employees to transfer to Dr. C. and that they would be informed that they could choose any insurance doctor in the district. Later Dr. B. wrote to say that one of the two employees who had signed a statement that they wished to stay on his list had been dismissed, and that others whom he had asked to sign a similar statement had declined for fear of dismissal. Both Dr. B., the successor, and Dr. C., the "house doctor," appeared before the committee. Dr. B. brought no witnesses as he said the insured persons feared their appearance might jeopardise their positions with the firm.

Dr. C. stated that just after he had seen the secretary to the firm, and had agreed to act as medical adviser to the inmates of the hostel, he left London for his holiday. He had had no previous experience of insurance work and was quite unaware that his acceptance of the insured persons was detrimental to Dr. B. He was also unaware that a notice had been posted in the hostel until Dr. B.'s letter acquainted him of the fact. He called as witness the secretary of the firm, who confirmed everything that the doctor had said. The secretary explained that the sole desire of the firm was to see that their employees were on the list of an insurance doctor. He now realised that the exhibition of the offending notice was contrary to the National Health Insurance Acts, but he was not aware of this fact at the time the notice was exhibited. He added that no employee had been dismissed because she had signed a statement, but that one had been dismissed because she was unsatisfactory. The committee came to the conclusion that the canvassing which took place on Dr. C.'s behalf was entirely without his knowledge and consent, and they directed that this decision should be conveyed to all the parties concerned. The clerk of the insurance committee was however asked to communicate with the firm pointing out that the notice was an interference with the right of free choice of doctor conferred on every insured person by the National Insurance Acts and suggesting that a further notice should be exhibited in the hostel informing the employees that they are entitled to apply for admission to the list of any insurance practitioner without fear of penalty.

This was done and the firm readily concurred in the suggestion. But the incident illustrates the difficulty which sometimes occurs of convincing employers that although they pay a considerable proportion of the value of stamps affixed to contribution cards they have no right to interfere with any of the benefits conferred upon the insured person.

Incapacity after Confinement

Sickness or disablement benefit is in no circumstances payable to a married woman in respect of incapacity occurring during the four weeks following confinement. Unmarried women, on the other hand, although ordinarily disentitled to sickness or disablement benefit during those four weeks can be paid sickness or disablement benefit if it can be shown that the incapacity is not connected directly or indirectly

with the confinement. Section 13 (7) of the 1924 Act is the relative enactment on the subject. An insured person recently complained to the Scottish Department of Health that her insurance practitioner had refused to issue a certificate of incapacity for work to her. The reply of the doctor showed *inter alia* that three weeks after the confinement of the insured person, which took place in an institution, she requested him to give her a certificate of incapacity but that, having regard to the provisions which are set out above, he had refused to certify. Furthermore, any disability which the patient was suffering was due to her confinement three weeks previously and this confirmed him in his refusal to issue the certificate of incapacity. The patient's father later informed the doctor that the approved society were ready and willing to pay the benefit if he would issue the necessary certificates, whereupon he asked that this request might be put into writing. Needless to say, no such written request was forthcoming, but the patient's father returned to the doctor and stated that he would refer the matter to the Department of Health, in which course the doctor acquiesced. The insured person then went to the employment exchange and "signed on." A copy of the letter

from the doctor was transmitted to the Department of Health, who replied that in the circumstances stated a certificate of incapacity on a date within four weeks after the date of the insured person's confinement was not required for National Health Insurance purposes and that the doctor was accordingly in order in refusing to issue such a certificate. The clerk of the insurance committee is now to write and request the observations of the approved society of which the insured person is a member. It is, perhaps, desirable that insurance practitioners should again be warned of the undesirability of paying too much attention to messages alleged to have emanated from approved societies or their representatives.

This occurred at Glasgow. The London panel committee has also taken note of the fact that although the certification of pregnancy has been eased of late the approved societies seem to have done nothing to curb the activities of their agents who continue to encourage pregnant women to apply for sickness benefit for a number of weeks before and after confinement. This action adds to the doctor's difficulty as the patient believes what she prefers to believe, especially when the agent's tale is in conformity with her own desires.

PUBLIC HEALTH

The River Tees : a Survey of Pollution

THE Water Pollution Research Board has just issued a second report¹ on the River Tees which was selected some time ago for close investigation as a typical polluted, but not too heavily polluted, river. The object of both these reports has been to find the effect of different sources of pollution and to determine to what extent the various discharges should be purified if serious pollution is to be avoided.

The present report concerns the tidal reaches of the Tees, which extend from High Worsall to the sea, a distance of about 25 miles, and include the water flowing past Stockton, where the industrial and urban features become marked, Middlesbrough and near Billingham. The salmon and trout fishery, once important, is declining, and it is evident that this is due mainly to sewage and industrial pollution. The nature of this and its effects on the chemical character of the water and on the varied flora and fauna have been investigated by a group of chemists and biologists, who have been able to compare their findings with those on unpolluted streams—the Tay and the Tamar—somewhat similarly situated with regard to the sea, that is, possessing like the Tees fairly well-defined fresh-water, brackish and marine regions. The Tees is a river in which fresh and salt water do not mix intimately; definite stratification occurs, the lighter fresh water floating over the salt water coming from or ebbing to the sea. It is remarkable that not only in the Tees but in the two other rivers the zone of greatest variation in salinity is also that of most restricted flora and fauna. Since, in the Tees, this zone is also that of maximum pollution the comparison is valuable as the sparsity of life might have been entirely attributed to pollution, whereas it is evidently in part due to the relatively few species which have been able to accommodate their mode of living to rapid changes of concentration of ions and consequent

variation of osmotic pressure in the medium in which they live. That pollution also has some share in causing the relative *paucity* of life in the Tees is shown by the very few *minnows* and shrimps in the region in question.

The kinds of pollution reaching the Tees are very varied. The untreated sewage of 280,000 people is an important factor, but effluents from coke oven by-product works contribute approximately two tons of tar acids and a ton of cyanide daily. The effect of these rather active poisons on living things already debilitated by whatever specific toxic effect (if any) sewage may possess, and by its demands on dissolved oxygen (at times reducing the saturation of this gas in the water to 5 per cent. of that found in pure water in equilibrium with air) is obviously likely to be great. It appears that cyanides are more virulent than tar acids, although the experiments made for the Ministry of Fisheries several years ago showed tar acids to be very deadly to the trout at Alresford, Hants.

In the Tees, as we believe is the case in most polluted rivers, the variation of dissolved oxygen is seasonal. In summer, when the high temperature of the water increases the rate of biochemical action, the demand of organic polluting matters for oxygen approaches closely the rate of absorption of oxygen from the air, supplemented though this is by photosynthetic processes; the decreased fresh-water flow also leads to a more lengthy sojourn of polluting matters in the restricted waters of the river. In winter, slow rates of demand and high fresh-water flow allow a higher oxygen content.

This brilliant research, which is a fine example of what can be done by a group of allied workers in different fields, has not been confined to an investigation of conditions in the river, but has been supplemented by experimental work in the laboratory on the action of the relevant effluents and their constituents on various organisms and on the means of purification of effluents. These and other inquiries have thrown light on the problem of polluted rivers in general and the means of restoring them to some-

GENERAL MEDICAL COUNCIL

WINTER SESSION, NOV. 26TH-DEC. 3RD, 1935

Penal Cases Referred by the Dental Board

The Case of Aaron Leslie Barnett, registered as of 5, Robert-street, Londonderry, "Dentist 1921," the erasure of whose name from the Dental Register was recommended after investigation of the following charge :—

That being a registered dentist you have canvassed for the purpose of obtaining patients and in particular in or about the month of March, 1934, canvassed Mrs. Ruby Hutton and subsequently extracted her teeth and supplied her with a denture.

Mr. Barnett attended and was represented by Mr. Ifor Lloyd, counsel, instructed by Mr. Meyer Cohen, solicitor. Mr. Lloyd addressed the Council, pointing out that the only evidence before the Board had been an illiterate woman from Londonderry and a "free sample" post card ordering $\frac{1}{4}$ lb. of Ty-phoo tea to be sent to her on Mr. Barnett's recommendation. After deliberation in camera the President announced that the Registrar had been directed to erase Mr. Barnett's name from the Dental Register.

The Case of William Ainslie Duncan, registered as of 5, Myrtle-street, Glasgow, "Dentist 1921," who had appeared before the Dental Board on the charge :—

That being a registered dentist : (1) You have permitted an unregistered person—namely, Daniel MacLachlan, to practise dentistry in your name, and in particular in connexion with the dental treatment of Wilhelmina Davidson and Robert Kelly, and that you have thereby enabled the said Daniel MacLachlan to practise as if he were registered. (2) You have assisted, counselled, and encouraged an unregistered person—namely, Daniel MacLachlan, to practise dentistry for your own benefit.

The Dental Board had found the charges proved and recommended the erasure of Mr. Duncan's name.

Mr. Duncan was not present, nor was he represented. After deliberation in camera the President announced that the Registrar had been directed to erase his name.

Penal Cases Adjourned from Previous Sessions

The Council then proceeded to the consideration, adjourned from May 28th, 1935, of the *Case of Aldo Castellani*, registered as of 23, Harley-street, London, W.1, Hon. K.C.M.G., M.D. Univ. Florence, 1899; M. 1906, F. 1922, R.C.P. Lond., who had been summoned to appear before the Council on a charge of infamous conduct in a professional respect. Sir Aldo appeared and was accompanied by Mr. T. Carthew, counsel instructed by Messrs. Le Brasseur and Oakley, solicitors for the London and Counties Medical Protection Society. Mr. G. O. Slade, counsel instructed by Messrs. Pennington and Son, appeared for the complainant and applied to the Council for a hearing in camera. Mr. Carthew opposed this application as his client wished the charges to be heard in public

to avoid misunderstanding. The Council decided to hear the case in camera, and after the hearing the President announced that the charges had not been found proved.

New Penal Cases

A CHARGE OF PROFESSIONAL MISCONDUCT

The Case of Dorothy Miller, registered as of Hollyburn P.O., West Vancouver, B.C., Canada. M.B., Ch.B. 1916, U.Glasg., who had been summoned to appear before the Council on the following charge :—

That being a registered medical practitioner you abused your position by committing adultery with Roy Keating Clay, who and whose wife were patients of yours, of which adultery you were found guilty by the decree of the Supreme Court of British Columbia in Divorce and Matrimonial Causes dated June 14th, 1934. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The complainant was Mrs. Alice Keating Clay.

Complainant and respondent did not appear, but the latter was represented by Mr. W. G. Fordham, Council, instructed by Messrs. Johnson, Jecks, and Colclough.

Mr. Winterbottom put in the documents of complainant's case and a transcript of the divorce case. Mrs. Clay had declared, he said, that during their residence in West Vancouver Dr. Miller had attended them professionally from March, 1929, and they had called her in without previous acquaintance. Accounts had been rendered and paid by both husband and wife. Mr. Clay had been attended continuously for paratyphoid in 1929. In 1930 Dr. Miller had taken Mr. Clay in her own car to hospital for a diagnostic test; for this he had paid by cheque. Copies of prescriptions were exhibited. Dr. Miller's reply was that prescriptions were generally dictated by telephone in West Vancouver and she had often telephoned the drug store on behalf of friends and patients. She did not consider that this constituted professional relationship. Friends and patients often telephoned repeat orders of prescriptions. Mr. Winterbottom suggested that one or two of the prescriptions were not such as a layman could telephone. In 1930 Mr. and Mrs. Clay had gone to China for a trip and before their departure Dr. Miller had refused to accept payment on the ground of friendship. They had therefore brought back presents for the doctor from China, and had subsequently given her gifts.

Mr. Winterbottom read five statutory declarations from friends of the Clays, confirming that Dr. Miller had been regarded as the family doctor, and that the first introduction had been a professional one. One writer declared that the Clays had been a model couple until the doctor had come between them. The divorce case had been heard on June 4th, 1934. Mr. Clay had there said that trouble between him and his wife had started about two years before. Mr. Clay had declared that his wife refused to divorce him for any offence other than those with Dr. Miller.

Mr. Fordham then addressed the Council and submitted that when a case of this kind depended solely on affidavit, the charges ought to be very thoroughly proved. It was unfortunate that the evidence of Mrs. Clay and two of her witnesses had been sworn before a notary who was a partner in the firm of solicitors employed by her. He read two statutory declarations, from a Mr. and Mrs. Glover, wherein it was stated that Mrs. Clay and her lawyer had brought much pressure to bear on them to sign affidavits of which they did not approve. Mrs. Glover had no knowledge of any treatment of Mr. Clay

(Continued from previous page)

thing like a normal condition. It is hardly too much to hope that in time to come these workers will be reporting on a restored Tees, again full of fish, whilst still supporting flourishing industries. This is the *raison d'être* of the Water Pollution Research Board.

by Dr. Miller or of any improper conduct. Mrs. Clay and her lawyer separately had told Mrs. Glover she was their only witness and she must come, and the latter had offered to pay for them what they owed to Dr. Miller if Mrs. Glover would go and "sign the papers we want." The lawyer had become very angry and had said: "We are going to get Dr. Miller out of the profession, even if she is a good doctor, but to do that we must have Mrs. Glover's affidavit." Mrs. Glover had been working in the Clays' house from 1929-1931. Mr. Fordham argued that at the time of the alleged offence the relationship of doctor and patient had long ceased to exist. The parties had been on terms of social intimacy. The first charge of misconduct was 1934. The only professional accounts paid had been on behalf of the wife, not the husband, and all treatment had ceased in 1932. Mr. Clay had called in another doctor in 1929 and 1931. If relation of doctor and patient were ever to cease, Mr. Fordham argued, there could be no more potent test than the consultation of another doctor. Mrs. Clay had not contemplated divorce proceedings (which had in fact been taken) but had preferred to report the matter to the Council. Dr. Miller claimed that she was continually meeting these people and they were continually asking her what to use for various minor ailments; the prescriptions put in evidence were the result of telephone messages, written out by the chemist for his records. The only presents given to respondent were given in 1930 and could not therefore refer to the alleged professional attendances in 1931 and 1932. It was admitted that the parties met for the first time on a professional basis, but this had ceased at the end of 1929 and had never been resumed. It was common ground that it had ceased in 1932. The adultery in 1934 had no sort of relevance to the opportunities of the doctor during professional attendance in 1929. With a woman doctor the circumstances were in the very nature of things different from the abuse by a man of privileged access to the bedside of a woman patient. No opportunity had been abused here and no trust broken.

Mr. Winterbottom, replying, pointed out that six prescriptions had been given within 21 days, but agreed that there was no evidence of remuneration after the first two payments of 9 dollars.

After deliberation in camera the President announced that the Council had not seen fit to direct the erasure of Dr. Miller's name.

CHARGES OF DRUNKENNESS

The Case of Florence Joseph O'Driscoll, registered as of West House, Ramsey, I.O.M., M.B., B.Ch. 1928, N.U.Irel., who had been summoned to appear before the Council on the following charge:—

That you were convicted: (1) On August 3rd, 1931, at the Clerkenwell Police-court, of being drunk, and were fined 10s. and 11s. costs, or seven days' imprisonment; (2) On August 16th, 1933, at the Liverpool City Police-court, of being drunk and incapable, and were fined 10s. or ten days' imprisonment; (3) On July 30th, 1935, at the Liverpool City Police-court, of being drunk and disorderly, and were fined 40s. or one month's imprisonment.

Mr. O'Driscoll appeared, but was not accompanied by any legal representative. Mr. F. P. Winterbottom, solicitor to the Council, put in the charges and police reports and read correspondence about the case. Respondent had pleaded loss of sleep and promised complete abstinence after the second conviction. In the third conviction respondent had been arrested in company with a woman who had previous convictions for indecent conduct and prostitution.

Mr. O'Driscoll addressed the Council, pointing out that at the material times he had not been engaged in medical work. The woman had accosted him and, before anything else could happen, the policeman had arrived. He expressed his deep regret and promised to abstain in future.

After deliberation in camera the President announced that the Council had decided to postpone judgment for twelve months subject to the usual provisos as to testimonials and good conduct in the meanwhile.

The Case of John McCarren, registered as of Brookvale, Cavan, L., L.M. 1926, R.C.P. Irel.; L., L.M. 1926, R.C.S. Irel., who had been summoned to appear before the Council on the following charge:—

That you were convicted at the Liverpool City Police-court: (1) On April 2nd, 1930, of being drunk and disorderly, and were fined 20s. or 11 days' imprisonment; (2) On Jan. 13th, 1932 (in the name of John Patrick McCarren), of being drunk and disorderly, and were fined 15s. or six days' imprisonment; (3) On April 30th, 1935 (in the name of John Gerard McCarren), of being drunk and incapable, and were fined 10s. or six days' imprisonment; (4) On May 2nd, 1935 (in the name of John Gerard McCarren), of being drunk and incapable, and were fined 20s. or 11 days' imprisonment.

Mr. McCarren did not appear, nor was he represented. Mr. Winterbottom laid the facts and correspondence before the Council. Respondent had written that he had not practised medicine, except for a few days, during the previous year and that he had no intention of practising, except in case of war, in the near future. He sent testimonials from the Cavan Board of Health.

After deliberation the President announced that the Council had postponed judgment until November, 1936, subject to the usual provisos; it would be desirable in his own interest that Mr. McCarren should then attend.

The Case, adjourned from Nov. 28th, 1934, of *George Francis Maher*, registered as of Ballymore House, Goold's Cross, Co. Tipperary, L.R.C.P. Edin. 1925; L.R.C.S. Edin. 1925; L.R.F.P.S. Glasg. 1925, who had been summoned to appear before the Council on a charge of having been convicted twice of driving a motor-car under the influence of drink. Judgment had been postponed.¹

Mr. Maher attended, and Mr. Winterbottom read three testimonials to his conduct. After deliberation the President announced that the Council had decided not to erase Mr. Maher's name from the Register.

The Case of Robert Louis Portway, registered as of c/o Westminster Bank, 34, Borough High-street, London, S.E.1, M.R.C.S. Eng. 1916; L.R.C.P. Lond. 1916; D.P.H., R.C.P.S. Eng. 1921, who had been summoned to appear before the Council on the following charge:—

That you were convicted: (1) On June 11th, 1930, at Bow-street Police-court, of exceeding the speed limit in a motor-car, and were fined 15s.; (2) At the County of London Sessions commencing on Oct. 20th, 1931, of driving a motor-car whilst under the influence of drink, and were fined £50 and £25 costs and disqualified for holding a driving licence for five years; (3) On May 28th, 1935, at the Marlborough-street Police-court, of being drunk and disorderly, and were fined 20s. and 10s. 6d. costs.

Mr. Portway appeared, accompanied by Mr. Oswald Hempson, solicitor. Mr. Winterbottom put in the convictions and read correspondence. Mr. Hempson objected to the introduction of police

¹ THE LANCET, 1934, II., 1254.

reports. The Legal Assessor said that it was the practice of the Council to accept such reports rather than bring police officers to give evidence, but if Mr. Hempson maintained his objection he would have to rule the statements of police officers out of order. Mr. Hempson did not press his objection, but said that if they were read he would have to call his client to refute them.

Mr. Portway, giving evidence, explained that at 1 o'clock on the night of May 28th he was returning from a dance and was accosted by two prostitutes. He had crossed to the point duty policeman to complain and by the time the policeman looked round the women had gone away and the policeman had taken him straight to the station. He admitted having taken some drink and having lost his temper. He had been very worried on that day by a quarrel with his only surviving relative, but since then he had been very moderate in drinking and was determined to go straight in future. In answer to the President, he said he was not now in practice. Mr. Hempson briefly addressed the Council and put in testimonials to Mr. Portway's character.

After deliberation in camera the President announced that the Council took a grave view of such offences, but had decided to postpone judgment for twelve months.

RESTORATIONS

The President announced that the Council had decided to restore to the Medical Register the names of James Lionel Bocarro, Philip Henry, and Harry Rubinstein.

INFRINGEMENT OF D.D.A. REGULATIONS

The Case, adjourned from May 29th, 1935, of *Valentine Robert Hirsch*, formerly registered as of 70, Westbourne-terrace, W.2, and now registered as of 17, St. Stephen's-square, W.2, M.R.C.S. Eng. 1916; L.R.C.P. Lond 1916, who had been summoned to appear before the Council on the following charge:—

That you were on Oct. 31st, 1934, convicted at the Marylebone Police-court of the following misdemeanours, viz: (1) That being a person authorised to prescribe for dangerous drugs, you did fail to comply with the Regulations (date of offence, July 18th, 1934), and were fined £5 and 3 guineas costs; (2) That being a person authorised to prescribe for dangerous drugs, you did fail to comply with the Regulations (date of offence, August 24th, 1934), and were fined £5; (3) That being a person authorised to prescribe for dangerous drugs, you did fail to comply with the Regulations (date of offence, Sept. 17th, 1934), and were fined £5.

At the conclusion of the hearing on May 29th, 1935, when Mr. Hirsch was not present and was not represented, the President announced that the Council had decided to adjourn the consideration of the case until the November Session.

Mr. Hirsch now attended, accompanied by Dr. R. J. Hearn, Counsel.

Mr. Winterbottom outlined the case against respondent and Dr. Hearn addressed the Council, saying that respondent had really thought he was doing a service to the patient who was matron of a nursing-home. He had acted foolishly and unthinkingly.

Mr. Bone inquired which regulation had been infringed, and this was ascertained. He also asked if any application had been made to the Home Office for restoration of the licence, and Dr. Hearn replied that Mr. Hirsch was awaiting the result of this case.

After deliberation in camera the President said that the convictions proved that respondent had

not appreciated his responsibilities under the Act; nevertheless, the Council had not decided to direct the Registrar to remove his name, trusting that these convictions would be a lesson to him.

ALLEGED MISCONDUCT

The Case of Frank Beauchamp Martin, registered in the Colonial List as of c/o Westminster Bank, Haymarket, London, S.W.1, M.B., B.S. 1908, U.Melb.; F.R.C.S. Eng. 1919, who had been summoned to appear before the Council on the charge that being a registered medical practitioner he had abused his position by improper relations with a patient on various occasions between January, 1933, and January, 1935, during which period she was under his care, and that in relation to the facts so alleged he had been guilty of infamous conduct in a professional respect.

The respondent appeared, accompanied by Mr. O. Hempson, for the Medical Defence Union, and complainant was represented by Mr. W. A. L. Raeburn, counsel, instructed by Messrs. Julius White and Bywaters. The case, on the application of complainant's counsel, was heard in camera. After a hearing of two whole days, the President announced late on Monday night that the Council had not found the charges proved to its satisfaction.

Registration of Foreign Dentists

THE DENTAL EDUCATION AND EXAMINATION COMMITTEE had before it an unusually large number of applications for registration by foreign dentists. Sections 9 and 10 of the Dentists Act, 1878, enable the Council to authorise the registration in the Dentists Register as foreign dentists (without further examination in the United Kingdom) of persons who are not British subjects, or who have practised for more than ten years outside the United Kingdom, provided they have obtained some recognised certificate granted in a foreign country entitling its holder to practise dentistry or dental surgery and furnishing sufficient guarantees of the possession of the requisite knowledge and skill for its efficient practice. Should the foreign degree or qualification not appear in the list (on page lxxviii of the Dentists Register) the Council requires from the applicant such information as may enable the Council to determine whether the degree or qualification has been granted after a course of study and examination substantially equivalent to those required of candidates in this country. Having satisfied the committee in these particulars the following applicants are to gain access to the foreign list of the Dentists Register.

Adler, Max Martin, D.M.D.	Cohn, Erich, D.M.D.	U.Koenigsberg, 1922.

(Continued at foot of next page)

As your article states, such fully equipped teachers are available; but are their services being used by the teaching hospitals? Until they are, the student cannot be given an adequate background of training to prepare him to meet the problems which will confront him in any branch of clinical medicine or surgery which he will follow later. The public will continue to be inadequately served, and the charlatan will continue to flourish.

I am, Sir, yours faithfully,

Brook-street, W., Dec. 3rd.

RALPH A. NOBLE.

To the Editor of THE LANCET

SIR,—Your leading article of Nov. 23rd suggests that there is considerable disagreement about the teaching of medical psychology. The controversy which rages in various sections of the lay press shows that the general public feels a certain amount of dissatisfaction with the diagnosis and treatment of mental illness. It would seem to me that these two things are related. We do not know enough about medical psychology, psychopathology, and psychotherapy—particularly in relation to the psychoses. There is an urgent need for research. The research which is performed in mental hospitals is mainly done from an organic point of view and the work is carried out by an enthusiastic junior—the senior is awaiting the coming of a clinical nirvana in the shape of a superintendentship. On the other hand, the psychotherapist who works outside a mental hospital must, by the nature of his work, pass long hours in his consulting-room and has little time to correlate his findings. It is a pity that we have no proper organisation to encourage research in psychological medicine, and that there is no honour or prize, not necessarily of monetary value, given for the best research of the year. As it is, the research worker is never able to feel that his work is appreciated.

To me Dr. Ross is sugaring his pill so much that it is all sugar. Why should only that psychology which is acceptable "to all intelligent persons" be taught? Would any other branch of medicine accept such a restriction? Are there no other "warring schools" in any other branch of medicine? It would be more reasonable to teach impartially the different doctrines and let the student select what he feels is of value in exactly the same way as he does in any other branch of medicine. In any case the schools war on philosophical grounds and these are of less interest to the clinician than technical psychotherapy. A great deal of harm has been done to psychology by not emphasising to the student that the function of analytical psychotherapy is really to release emotion and that the sole aim in exploring the unconscious is to do this. If students were taught how to diagnose properly, then, when they became practitioners, they could sort out and treat the anxiety states and other minor surgery of the mind while passing on to the specialist the prepsychotics, severe hysterics, obsessionals, &c., for more severe operations.

It is better for the practitioner to learn to treat those cases which yield easily to treatment and not to attempt the more difficult ones. Every student should leave hospital with the knowledge how to do a simple analysis. If he uses this knowledge he will acquire a wisdom which will enable him to pick what he needs from the various schools of psychological thought.

I am, Sir, yours faithfully,

Harley-street, W., Nov. 29th.

CLIFFORD ALLEN.

THE MEDICAL REGISTER

To the Editor of THE LANCET

SIR,—I am directed by the President of the Council to say that he would be glad if you could publish this intimation that any orders for the office edition of the Medical Register, 1936, published by the Council at the special price of 10s. a copy, post free, must be received, with a remittance, at the office of the Council not later than Dec. 31st, 1935.

The office edition differs from the ordinary edition of the Register to the extent that it does not contain reprints of the Medical and Dentists Acts and other preliminary matter, and is printed on more inexpensive paper and bound in boards. It includes, however, the same entries relating to registered medical practitioners as are included in the ordinary edition, and is therefore equally serviceable to public authorities and others who find it necessary to ascertain whether particular persons are registered medical practitioners or not.

I am to take the opportunity of stating that the Council also prepare monthly lists of names added to, and removed from, the Register, and that particulars of the terms and conditions upon which copies of these lists may be made available can be obtained on application to the office of the Council.

I am, Sir, yours faithfully,

MICHAEL HESELTINE,

Registrar, General Medical Council.

44, Hallam-street, Portland-place, London, W., Dec. 2nd.

CAUSES AND TREATMENT OF OBESITY

DR. H. W. HALES writes:—May I make some corrections of your summary of my remarks at last week's meeting of the Section of Medicine of the Royal Society of Medicine? You stated that I viewed obesity as a symptom of oxidation deficiency produced by tissue and intestinal poisons; I actually said "by the combined action of food toxins and intestinal poisons." Again, you said: "There were certain toxic principles in food, especially meat, of which *avenin* was an important example." *Avenin* should read *arginine*. As is well known, arginine is an amino-acid which, according to Edlbacher and Mertz, is present in a very high concentration in cancerous tissue. It has been shown that inoculated cancerous growths in animals are speeded up by the injection of arginine, but are retarded by thyroxine. (Cf. Gilroy's articles in *Biochemical Journal*, 1930-31.) This suggests a reason for the value of thyroid and potassium permanganate in many chronic conditions, especially those involving the liver or ductless glands. Cancer seems to be progressing rapidly in meat-eating countries, and so the question of arginine appears to be of increasing importance. (I am indebted to Mr. C. B. Voge, Ph.D., for my information on this subject.) You have quoted me as saying that "Hunger was analogous to the withdrawal symptoms felt by drug addicts." The context showed that hunger referred to the particular craving for food experienced at the beginning of a fast, and it should be differentiated from the irresistible hunger which arises at the successful completion of such treatment. Lastly, I said "colonic detoxication by lavage with potassium permanganate as originally described by Nott." I do not find that other solutions are of much value.

HOSPITAL EXTENSIONS AT STROUD.—The county public assistance committee, on Nov. 19th, approved a scheme to spend £28,000 in remodelling and extending the Stroud Public Assistance Institution. A hospital block with 109 beds, a laundry, a dining-room, and alterations in the nurses' quarters are included in the plans.

MEDICAL NEWS

University of Cambridge

On Nov. 30th the following degrees were conferred:—

M.D.—E. H. Willoughby Lyle and T. K. S. Lyle.
M.B., B.Chir.—C. L. Collins, J. S. Cookson, B. T. Thorne, and A. H. M. Siddons.
M.B.—F. H. Finlaison and H. B. Tipler.

The following have been appointed members of the committee for medical radiology and electrology for 1936: Dr. T. S. Hele, Dr. G. S. Graham-Smith, Dr. G. H. Orton, Dr. E. P. Cumberbatch, Prof. Sidney Russ, and Dr. Russell Reynolds.

Society of Apothecaries of London

At recent examinations the following candidates were successful:—

MASTERY OF MIDWIFERY
 Marion Bow, M. W. Ginsberg, Hilda Linford, H. T. Tate, and Elizabeth S. Walker.

Queen Alexandra's Hospital for Officers

Lord Melchett presided at the sixteenth annual reunion dinner of this hospital held at the Hotel Splendid on Nov. 29th, when nearly fifty of the former patients and members of the nursing staff were present. In proposing the health of the former patients, Lord Melchett sounded a note of hope and confidence, and in his reply, General T. A. Bigge expressed the appreciation of the officers for the devoted work of Mr. and Mrs. Herbert Paterson, the matron, nurses, and voluntary workers of the hospital.

Royal Free Hospital

On Nov. 28th the annual dinner of this hospital was held at the Savoy Hotel under the chairmanship of Dr. H. Haldin-Davis, who has lately resigned his position of dermatologist to the hospital and been elected to the consulting staff. In proposing the toast of the school and hospital he told the guests of some of the honours received during the past year. The Duke of York had consented to become president of the hospital; Dr. Chodak Gregory had been elected a Fellow of the Royal College of Physicians of London, being the second woman to be admitted to the fellowship; while Sir Alan Anderson had been elected M.P. for the City of London, and as a result had had to resign from the treasurership of the hospital though he was remaining on the council. Dr. Haldin-Davis referred to the generous provision which Lord Riddell, their late president, had made for the hospital in his will. Dr. D. C. Hare in an amusing speech proposed the health of the guests, who included Dr. Letitia Fairfield, Commander Stephen King-Hall, Sir Walter Moberly, Dr. Bentley Purchase, and Mr. and Mrs. F. W. Pethwick-Lawrence. Dr. Fairfield in reply spoke of the unique part which the voluntary hospitals played in the lives of the poor of London. If a rivalry existed between the L.C.C. as a hospital authority and the voluntary hospitals, it was a friendly and coöperative rivalry. Commander King-Hall who also replied related some incidents of the unorthodox but effective practice of medicine by amateurs in the Navy before admitting frankly his dissatisfaction with the tangible results of orthodox medicine. We live, he said, in a framework of time and space, but while we now voyage to the stratosphere in balloons and to the depths in submarines, our expectation of life had been only increased by a beggarly 15 years and the service for providing "spare parts" to our bodies was still inadequate. When time for eating and sleeping was deducted from our years of full activity he reckoned that we had but some 4261 working days at our disposal. Considering the enormous sums of money spent on research in other directions he felt that a grant of 20 million pounds to medical research would be proper; it would have great psychological value. Miss M. Rowland Jones proposed the health of the chairman. In dermatology, she said, it was easy to prescribe expensive lotions when what was needed was more soap and water and less food. But Dr. Haldin-Davis, like Elisha, did not hesitate to tell his patients to wash and be clean. The chairman in reply paid a tribute to Miss Widdows who had for many years acted with him as co-secretary for the dinner.

Voluntary Euthanasia

The inaugural public meeting of the Voluntary Euthanasia Legalisation Society will be held on Tuesday, Dec. 10th, at 8 p.m., in the Great Hall of the B.M.A. House, Tavistock-square. The chair will be taken by Lord Moynehan, president of the society, and the speakers include Mr. C. J. Bond, F.R.C.S., chairman of the executive committee, Dr. C. Killick Millard, hon. secretary, the Earl of Listowel, Lieut.-Colonel Sir Arnold Wilson, M.P., Miss Eleanor Rathbone, M.P., the Rev. Harold Anson, Master of the Temple, and the Rev. F. W. Norwood, D.D. The resolution to be presented at this meeting runs as follows: "That, in the interests of humanity, it is desirable that voluntary euthanasia should be legalised, subject to adequate safeguards, for persons who are suffering from incurable, fatal, and painful disease." Admission to the meeting is free and questions will be invited.

Pinsent-Darwin Studentship in Mental Pathology

Official notice is given that an election to the above studentship will be made in January, 1936. The studentship is of the annual value of not less than £225, and is tenable for three years. The student must engage in original research into any problem having a bearing on mental defects, diseases, or disorders, but may carry on educational or other work concurrently. Applications for appointment to the studentship should be sent before Jan. 1st to the secretary, Pinsent-Darwin Studentship, Psychological Laboratory, Cambridge. Applicants should state their age and qualifications and the general nature of the research that they wish to undertake. No testimonials are required, but applicants should give the names of not more than three referees.

Royal Surgical Aid Society

The 73rd annual meeting of this society will be held at the Mansion House, London, at 4 p.m. on Monday next, Dec. 9th, under the presidency of the Lord Mayor. The speakers will include Prof. G. Grey Turner, F.R.C.S., and Sir William Beveridge.

The Post-Certificate School

On Friday, Dec. 13th, a reunion will be held for friends and students of this school (77, Southampton-street, Camberwell, London, S.E.) to meet Dr. John Fairbairn. At 4 p.m. tea will be given at St. John's Home, Watson-street, Deptford, and at 5 p.m. Dr. Fairbairn will give an address at the school in Camberwell, his subject being Post Certificate Work.

Joint Tuberculosis Council

At the November meeting of the council it was decided to invite the Association of Thoracic Surgeons to appoint a representative. The chief business was the consideration of a report presented by Dr. J. B. McDougall on behalf of the Employment Committee dealing broadly with care and after-care schemes in this country and abroad. The circulation of this report was left to the British Legion Press. On behalf of the Institutions Committee Dr. F. J. C. Blackmore presented a note on tuberculosis institutions and chest hospitals. It was resolved that "This Council is of the opinion that the benefits of major surgery for both tuberculous and non-tuberculous conditions should be available to every patient in need of such treatment, and considers that steps should be taken by local authorities to provide facilities at tuberculosis institutions if adequate arrangements have not been, or cannot be, made at other institutions." A committee was appointed to consider and report to the next meeting on the standardisation of blood sedimentation tests. Dr. W. Brand gave an account of post-graduate courses held during the year. The course at the City of London Hospital had 22 participants, the study tour in Denmark (June 1st to 15th) 10 members. Dr. Peter Edwards had given six short intensive courses, and from Nov. 4th to 9th a course was held at the Brompton Hospital. A letter had been received from the College of Nursing asking for advice about precautions to prevent tuberculous infection among nurses. Dr. Esther Carling, Dr. Jane Walker, and Dr. James Watt were asked to report on this.

Royal Society of Medicine

The house and library of the society will be closed from Monday, Dec. 23rd, to Saturday, the 28th, inclusive.

Leeds School of Medicine

At the annual dinner of past and present students of this school, with Mr. E. R. Flint in the chair, Mr. C. H. Robinson, proposing The Staff, warned them that the students had no intention of specialising in each of the lecturers' special subjects. Responding, Mr. B. L. Jeaffreson spoke of the danger of surgery overshadowing medicine in the practice of the Infirmary; medicine pure and simple was just as important as surgery, if not more so. Dr. Stanley Sykes, proposing Past and Present Students, said that there were two stages in the life of the general practitioner. In the first, people said: "He seems a very nice doctor, but he is too young and inexperienced." In the second they said: "He is a very experienced doctor, but he is too old and out-of-date in his methods." There was no intermediate stage. In his response Mr. D. W. Currie defined medicine as "the art of amusing the patient while nature effects the cure."

Spahlinger Vaccine

A joint committee of the Medical Research Council and the Agricultural Research Council on Tuberculosis has issued in the form of a green paper (H.M. Stationery Office, 2d.) its observations on the experiment with Spahlinger vaccine in Northern Ireland (see THE LANCET, Oct. 19th, p. 892). The joint committee concludes that a case has been made out for further investigation, and that a thorough test should be made in this country, if Mr. Spahlinger is found willing to supply vaccine in sufficient quantity for the inoculation of a suitable series of animals. The committee urges however that, until the vaccine has been shown by further and extended experiments to be effective against natural as well as experimental methods of infection, its practical application should be deferred, and it deprecates the enforced general use of the vaccine until a thorough investigation has been made. The observations are signed by Dr. J. A. Arkwright, F.R.S. (chairman), Sir Merrik Burrell, Prof. J. B. Buxton, F.R.C.V.S., Prof. S. L. Cummins, M.D., Capt. S. R. Douglas, F.R.S., Mr. G. W. Dunkin, M.R.C.V.S. (joint secretary), Dr. A. Stanley Griffith, and Dr. N. F. Smith (joint secretary).

PARLIAMENT

NOTES ON CURRENT TOPICS**Opening of New Parliament**

THE first session of the new Parliament was opened on Tuesday, Dec. 3rd. Owing to the illness of Princess Victoria, who died subsequently, there was no Royal procession and the session was opened by Lords Commissioners, the King's Speech being read by the Lord Chancellor, Viscount Hailsham.

In the course of the Gracious Speech it was stated that the Government are convinced of the need for an early and substantial development of the educational services of the country. A Bill would be introduced to amend the law in England and Wales relating both to the age of compulsory school attendance and to assistance from public funds towards expenditure on voluntary school buildings. Action would be taken in coöperation with local authorities and others to increase the effectiveness of the other educational services. In particular, the improvement of the school medical arrangements, the extension of physical education, and the development of technical schools would receive the attention of the Government. The Government would continue to promote actively the development of the social services and to take vigorous measures to improve the health and physique of the nation. They would press forward the work of slum clearance in order to ensure that the programmes submitted by local authorities were carried out within the period contemplated, and they would encourage the active

administration of the Housing Acts of 1935 which enabled local authorities to make a direct attack on the evils of overcrowding. Careful consideration had been given by the Government to the organisation of the maternity services with a view to providing better care for women in childbirth and a Bill would be introduced for the provision by local authorities, in coöperation with voluntary associations, of an organised service of salaried midwives. The Government would continue to give close consideration to the further improvement of conditions in Scotland, and among measures to that end a Bill would be introduced providing for the raising of the school age.

Voluntary Hospitals (Paying Patients) Bill

In the House of Lords on Tuesday, Dec. 3rd, Lord LUKE presented the Voluntary Hospitals (Paying Patients) Bill, which was read a first time.

Debate on the Address

In the House of Commons on Tuesday, Dec. 3rd, Mr. W. W. WAKEFIELD (who wore the uniform of a flight lieutenant of the Royal Air Force with a black armlet) moved that a humble Address be presented to His Majesty thanking him for the Gracious Speech from the Throne. Mr. Wakefield said that the Gracious Speech had shown that there was little plausibility in charging the present Administration with neglect of the health of the people, particularly the well-being of the young. The revival of agriculture went hand in hand with the new realisation that we possessed in the rich soil of England all the essentials of a healthy diet. Milk was perhaps the outstanding example of a commodity which under the present handling was being increasingly consumed and produced. British agriculture, nurtured by science and sheltered in the transitional stage by tariffs, could build up the health of the rising generation. They had heard in the Gracious Speech that the school age was to be raised. There was another school from which they had played truant for too long; and it was only lately that they had set to work to establish minimum standards of health. They must banish "physical illiteracy" from their midst. External security was one essential. An unrelenting zeal for improvement at home was another.

Mr. BALDWIN, Prime Minister, said that the Government regarded the social reform part of their programme as one of the most important parts of it, and they had decided to begin with their education plans. They had to make their choice as to what piece of legislation they should bring forward. There was a piece of reform which they were most anxious to get on with, and that was a Bill for the revision and consolidation of the law relating to the safety, health, and welfare of factory workers. Legislation on that subject had been examined and contemplated by many Governments, not even, he believed, excluding the last Labour Government. The present Government hoped and proposed to introduce that Bill in their second session. Referring to the Government's education proposals, Mr. Baldwin said that there were many questions connected with the health and physique of the children and various subjects of that kind where progress had been made by consultation with the local authorities and those would be got on with at an early date as soon as the Government were in a position to see that their Bill had become law. There was nothing of greater importance to-day than the all-round improvement, both mentally and physically, of our education. The Government hoped in the course of the session to get a Bill through so that unemployment benefit might be available for agricultural labourers in the winter of next year. Among other things the measures would entail a review of what was known as the means test. The Government believed it was necessary to retain the principle that unemployment assistance to which no contributions had been paid could not be paid without regard to needs, and that it would be necessary for the House of Commons to consider

most carefully any alteration of the existing rules in order to remove any occasion of hardship, and in particular to ensure the integrity of the family being kept intact. (Cheers.)

There was a subject which had been near his heart for many years before he had attained a position where he might have a hand in putting it through. That was the question of maternity and midwives. Here was a question upon which there could be no political conflict. He would try to peg out a claim now early by begging the House to see when they came to that Bill that if it commended itself to the House they might do their best to get it through this session. He did hope with regard to that most important piece of social legislation that they might be in a position to see it law before they went away for the summer holidays.

The debate on the Address in reply to the Speech from the Throne was adjourned.

PAGE, A. P. M., M.D., M.R.C.P. Lond., Deputy Medical Superintendent at the City General Hospital, Leicester.

St. Thomas's Hospital.—The following appointments are announced:—

MITCHNER, P. H., M.S., M.D. Lond., F.R.C.S. Eng., Surgeon; BARRETT, N. R., M.Chir. Camb., F.R.C.S. Eng., Surgeon in Charge of Out-patients;

DOYNE, P. G., M.B. Oxon., F.R.C.S. Eng., Ophthalmic Surgeon; and

PENHAM, G. G., M.B. Camb., F.R.C.S. Eng., Ophthalmic Surgeon in Charge of Out-patients.

Certifying Surgeons under the Factory and Workshop Acts: Dr. R. F. SMITH (Melbourne District, Leicester); Dr.

W. R. C. CAMPBELL (Helensburgh District, Dumbarton).

Royal Society of Medicine

The house and library of the society will be closed from Monday, Dec. 23rd, to Saturday, the 28th, inclusive.

Leeds School of Medicine

At the annual dinner of past and present students of this school, with Mr. E. R. Flint in the chair, Mr. C. H. Robinson, proposing The Staff, warned them that the students had no intention of specialising in each of the lecturers' special subjects. Responding, Mr. B. L. Jeaffreson spoke of the danger of surgery overshadowing medicine in the practice of the Infirmary; medicine pure and simple was just as important as surgery, if not more so. Dr. Stanley Sykes, proposing Past and Present Students, said that there were two stages in the life of the general practitioner. In the first, people said: "He seems a very nice doctor, but he is too young and inexperienced." In the second they said: "He is a very experienced doctor, but he is too old and out-of-date in his methods." There was no intermediate stage. In his response Mr. D. W. Currie defined medicine as "the art of amusing the patient while nature effects the cure."

Spahlinger Vaccine

A joint committee of the Medical Research Council and the Agricultural Research Council on Tuberculosis has issued in the form of a green paper (H.M. Stationery Office, 2d.) its observations on the experiment with Spahlinger vaccine in Northern Ireland (see THE LANCET, Oct. 19th, p. 892). The joint committee concludes that a case has been made out for further investigation, and that a thorough test should be made in this country, if Mr. Spahlinger is found willing to supply vaccine in sufficient quantity for the inoculation of a suitable series of animals. The committee urges however that, until the vaccine has been shown by further and extended experiments to be effective against natural as well as experimental methods of infection, its practical application should be deferred, and it deprecates the enforced general use of the vaccine until a thorough investigation has been made. The observations are signed by Dr. J. A. Arkwright, F.R.S. (chairman), Sir Merrick Burrell, Prof. J. B. Buxton, F.R.C.V.S., Prof. S. L. Cummins, M.D., Capt. S. R. Douglas, F.R.S., Mr. G. W. Dunkin, M.R.C.V.S. (joint secretary), Dr. A. Stanley Griffith, and Dr. N. F. Smith (joint secretary).

PARLIAMENT

NOTES ON CURRENT TOPICS

Opening of New Parliament

THE first session of the new Parliament was opened on Tuesday, Dec. 3rd. Owing to the illness of Princess Victoria, who died subsequently, there was no Royal procession and the session was opened by Lords Commissioners, the King's Speech being read by the Lord Chancellor, Viscount Hailsham.

In the course of the Gracious Speech it was stated that the Government are convinced of the need for an early and substantial development of the educational services of the country. A Bill would be introduced to amend the law in England and Wales relating both to the age of compulsory school attendance and to assistance from public funds towards expenditure on voluntary school buildings. Action would be taken in co-operation with local authorities and others to increase the effectiveness of the other educational services. In particular, the improvement of the school medical arrangements, the extension of physical education, and the development of technical schools would receive the attention of the Government. The Government would continue to promote actively the development of the social services and to take vigorous measures to improve the health and physique of the nation. They would press forward the work of slum clearance in order to ensure that the programmes submitted by local authorities were carried out within the period contemplated, and they would encourage the active

administration of the Housing Acts of 1935 which enabled local authorities to make a direct attack on the evils of overcrowding. Careful consideration had been given by the Government to the organisation of the maternity services with a view to providing better care for women in childbirth and a Bill would be introduced for the provision by local authorities, in co-operation with voluntary associations, of an organised service of salaried midwives. The Government would continue to give close consideration to the further improvement of conditions in Scotland, and among measures to that end a Bill would be introduced providing for the raising of the school age.

Voluntary Hospitals (Paying Patients) Bill

NOTES, COMMENTS, AND ABSTRACTS

DR. JOHN HALL: SHAKESPEARE'S
SON-IN-LAW¹

No more fitting place could, I think, have been chosen for this commemoration of the 300th anniversary of Dr. Hall's death than this building—the home of his daughter Elizabeth and her husband Tom Nash—the windows of which look out on to the now vacant site of New Place in which the doctor lived and died. The documents and other objects which have been brought together for this occasion have been obtained from various sources—the records have come from the Stratford-upon-Avon Corporation archives, the collections of the Birthplace Trust, and the parish chest. The contemporary drug jars, mortars, and other reminders of the apothecary's art have been kindly lent by Dr. D. S. Murray and Mr. J. Whitmore Peck, and the very valuable case of early seventeenth century surgical instruments is a loan from the Royal College of Physicians of London. With regard to the documents it is remarkable that after such a lapse of time it should be possible to assemble such a collection, illustrating as it does the life of one of Stratford's most prominent townsmen—prominent not only for his close personal connexion with Shakespeare, and his influence on the poet's later work—but also on account of his own special qualities and his great renown in the town and neighbourhood. These records present all the dominant phases of the doctor's career as a townsman of Stratford-upon-Avon. We find there evidence of his shrewd and businesslike concern in the estate bequeathed to his wife by Shakespeare; his kindly nature in the preservation of the home of his wife's sister, Judith Quiney, when threatened with the loss of it through her husband's bibulous excesses; his earnest Puritanism in the discharge of his duties as a churchwarden for the borough; his munificence to the parish church; his service as a member of the town council; his efforts and failure to reconcile his work as a physician with the demands made upon his time by an inconsiderate corporation, and his subsequent expulsion from that body; and his championship of the vicar and litigation on his behalf against the town council; while from his printed case-book we can follow him up and down the county—and far outside it—treating rich and poor alike—"even such as hated him for his religion," recording his successful cures with many an expression of devout thanks for heavenly aid.

John Hall was born in 1576, the son of William Hall, a Worcestershire doctor, whom we find settled at Acton, Middlesex, at the time of his death in 1607. From the terms of his will he appears as an astrologist and alchemist. John Hall graduated B.A. at Oxford in 1595, three years later became M.A., and from Oxford he went to the continent, as many medical students did, and obtained a degree, probably in France. The first reference to his presence in Stratford is the entry in the parish register on June 5th, 1607, of his marriage to Shakespeare's elder daughter Susannah, she being then 24, he 31 years of age. In Stratford he soon acquired a large and fashionable practice, extending into and beyond the neighbouring shires. Catholics were among his patients, notwithstanding his Puritan views, in which, apparently, he had the full sympathy of his wife. Tradition connects him with the house in Old Town called Hall's Croft, from which he removed to New Place on Shakespeare's death in 1616.

Shakespeare's description of the lord Cerimon in *Pericles* might be a word-portrait of Dr. Hall.

Gentlemen roused from their beds by the storm, find Cerimon up and about at dawn, ready for patients that the tempest might bring, dispatching his man to the apothecary. He says in reply to their astonishment:

'Tis known I ever
Have studied phisic, through which secret art
By turning o'er authorities, I have
Together with my practice, made familiar
To me and to my aid the blest infusions
That dwell in vegetives, in metals, stones;
And I can speak of the disturbances
That Nature works, and of her cures; which doth give me
A more content in course of true delight
Than to be thirsty after tottering honour
Or tie my treasure up in silken bags
To please the fool and Death (III., ii., 31-42).

The lines that follow might be a prophesy of Hall's coming reputation:

Your honour has through Ephesus poured forth
Your charity, and hundreds call themselves
Your creatures who by you have been restored:
And not your knowledge, your personal pain, but even
Your purse still open, hath built Lord Cerimon
Such strong renown as Time shall never end (43-8).

I will not discuss at length the extent of Shakespeare's knowledge of medicine.

Dr. John Hall, with his wife and daughter Elizabeth, 8 years old, if not already in residence at New Place, came there from Old Town on the poet's death in 1616. The Stratford Corporation, eager to have him as a member, elected him a Burgess on March 14th, 1617. He pleaded his professional duties and was excused. He was an active churchman and Puritan, and a devoted admirer of the eloquent, headstrong vicar, Thomas Wilson. In 1622 he was again elected a Burgess and again excused. His practice had grown very considerably and he rode, with his surgeon's box behind him, so far afield as Northampton, Worcester, and Ludlow. His patients included the Earl of Warwick, the Earl and Countess of Northampton, Lady Beaufoy ("godly, honest, being of a noble extract, healthful till the age of 28, which was 1617 July 1"), Lady Rouse, Mistress Mary Talbot ("a catholic, fair", "... such as hated him for his religion often made use of him"), Lady Puckering, Lady Browne of Radford, Lady Smith ("Roman Catholic, cruelly afflicted with wind"). Lady Dickenson ("fair, pious, chaste, vexed with pain of the head"), Lady Underhill and other of her family, Sheldons, Throgmortons, Rainsfords, Master Drayton ("an excellent poet, labouring of a tertian") and many others of note. Of his wife and daughter, he writes (in Latin): "Mistress Hall of Stratford, my wife, being miserably tormented with the colic" ... "was troubled with the scurvy, accompanied with pains of the loins, melancholy etc. ... I freed her from pain Feb. 9, 1630/1." Of their daughter, Shakespeare's grand-daughter, he records: "Elizabeth Hall my only daughter, was vexed with *tortura oris* or the convulsion of the mouth and was happily cured ... 5 Jan. 1624/5." In the beginning of April she went to London (probably to participate with her father in functions consequent on the death of King James on March 24th, and the accession of Charles I.), and returning homewards the 22nd of the said month "she took cold and fell into the said distemper on the contrary side of the face, and although grievously afflicted with it, yet by the blessing of God she was cured in sixteen days as followeth ... her neck was fomented with aqua vitae, in which was infused nutmegs, cinnamon, cloves, pepper; she ate nutmegs often. In the same year May the 24th, she was afflicted with an erratic fever: sometimes she was hot, bye and bye sweating, again cold, all in the space of half an hour, and thus she was vexed oft in a day. [Then he gives the prescription and adds] Thus was she delivered from death and deadly disease and was well for many years, to God be praise."

On March 1st, 1624-25, Dr. Hall assigned to the corporation for £400 the lease, which had still eleven

¹ The substance of an address delivered in the New Place Museum, Stratford-upon-Avon, on Monday, Nov. 25th, to mark the tercentenary of Dr. John Hall, Shakespeare's son-in-law. The address was delivered by Mr. FREDERICK C. WELLS, F.S.A., secretary and librarian to the Shakespeare's Birthplace Trust, and was illustrated by original records and other objects bearing on the life of Dr. John Hall.

years to run, of the tithes of Old Stratford, Welcombe, and Bishopston, which Shakespeare had purchased for £440 in 1605, and bequeathed to his daughter and her husband. In February, 1626, he was fined £10 for refusing a knighthood on the Coronation of King Charles I. On April 22nd in that year his daughter Elizabeth was married to Thomas Nash of Lincoln's Inn, son of Anthony Nash of Welcombe, to whom her grandfather bequeathed a memorial ring. She was just over 17, he just under 33 years of age. In 1628-29 Dr. Hall, the ardent supporter of the vicar, Thomas Wilson, served as a churchwarden for the parish. With his fellow-wardens, Anthony Smith and George Barton, he fulfilled his duties energetically, presenting parishioners for "loitering forth of church at sermon-time," "sleeping in the belfry with a hat on upon the Sabbath," "keeping drinking in a house on the Sabbath," and "in the company of an excommunicated person," keeping "naughty company," "wearing a hat in church," and being a "common romler," "being abroad seen by the Constable at sermon-time," "for late coming to Church," and "having no employment but laziness," "using beastly behaviour," "calling a woman witch," and "being a common swearer and blasphemer" or "drunkard." Much against his will Dr. Hall was elected a Burgess in May, 1632. Twice before he had successfully made excuse, but now he had to yield, partly to answer for his participation with the vicar in suits against the corporation. His membership lasted but sixteen months, and his presence when he did attend the council meetings was, to say the least, disturbing. The minutes of June 30th, 1632, record that he had neglected to attend and take his oath, although warned by both the chamberlains and the sergeants. He was warned again for July 6th, but in response to a pleading and indignant letter from a patient demanding his attendance he again made default.

[This letter, which was exhibited at the meeting, set forth in an urgent way the claims of professional over public duty.]

Hall had to contend with the family difficulties of his brother-in-law, Thomas Quynney of The Cage Tavern, now the Judith Quynney Café. Quynney, who was a vintner, fell, like Bardolf, a victim to the temptations of his calling. He was fined for absence from corporation meetings, for swearing, for suffering tipping in his house, and was passed over for promotion to aldermanic rank. On March 13th, 1633, Dr. Hall, his son-in-law Thomas Nash, and Richard Watts, who had married Quynney's sister Mary, took over the lease of the Cage in trust for his wife and children. [This document was also exhibited.]

On one occasion Hall was called upon to answer and submit himself to the corporation for abusive speeches against the bailiff, Richard Castle, known locally as "Shake-Elbows." Influence with Wilson, the vicar, and the Bishop had enabled the doctor to change his pew in the church from one near the pulpit on the south of the nave (that hitherto allotted to New Place and no doubt occupied by Shakespeare and his family) to another on the north side of the nave, at the upper end, "enjoyed time out of mind" by the aldermen and their wives. The bailiff and his brethren of the council not unnaturally resented their exchange. They objected also to Hall's denunciation of them for a breach of contract with the vicar. This was one of Dr. Hall's last attendances and doubtless a stormy one. On Oct. 9th, by 19 votes to 3, he was expelled from the council for "wilful breach of orders, sundry other misdemeanours, and continual disturbances." A Sunday or two later a scuffle occurred for possession of the aldermanic pew which led to the vicar holding a special court at New Place. The breach between vicar and corporation widened. He and Dr. Hall filed a petition in Chancery for the increase of the stipends of both vicar and schoolmaster, "according to the intent of the Charters." Notwithstanding the doctor's sale to the corporation of his lease of the tithes "for

less money than the same was worth by a hundred pounds at least" to maintain the vicar's salary to £60, they had reduced it, and for about the space of ten years last past, they had "utterly suppressed, omitted & neglected the payment of £20 per annum to the Schoolmaster." They charged the corporation, moreover, with "feasting and private use of the revenues." Interesting as they are, however, the details of the quarrel are too long to recapitulate here. Dr. Nathaniel Brent, the Vicar's General of the Diocese, opened an inquiry at Stratford. He awarded Dr. Hall his new pew "on the north side of the nave at the upper end" if he decided within a month to take it. In his evidence Dr. Hall states that he and his son-in-law, Thomas Nash, "did paye and contribute deeply towards the repayres of the sayd Church, and that he the sayd Mr. Hall had bene a benefactor and bestowed a new pulpit at his owne charge, and alsoe that the seate was assigned unto him by the Lord Bushopp of the diocese by an instrument vnder his episcopall seale wch, he then produced." [This document was also exhibited.]

The vicar was suspended for three months. Hall did not long survive his friend's suspension. He died suddenly on Nov. 25th within a few days of his neighbours, Henry Norman and Richard Walford. They may have been carried off by the same malady—for which perhaps he attended his fellow victims with fatal consequence. The burial entry in the parish register describes him as "Medicus Peritissimus." On his grave, near to Shakespeare's, were inscribed the lines—being translated—"Here lies Hall, very renowned for his medical skill, awaiting the joys of the Kingdom of God. Worthy was he, for his merits, to outdo Nestor in years, but on earth a like Day lays hands on all."

Mr. Wellstood closed his interesting lecture by a reference to the case-books and confidential papers, some no doubt inherited from Shakespeare, which were bequeathed by Hall in his will to his son-in-law Tom Nash. Hall's manuscript books were bought by one Dr. James Cook, and a translation of selected cases was published in 1657 and again in 1679 and 1683. These volumes were exhibited with photographs of certain of Dr. Hall's manuscript pages now in the British Museum. Hall's familiarity in the making up of his prescriptions was indicated by the number of his drug jars which were exhibited. The surgical instruments exhibited were in use in Hall's time and represent the armamentarium of a doctor of the Stuart period.* Of these, Mr. Wellstood said: They were made probably about 1631, and were presented to the College of Physicians of London in 1635 by Dr. Thomas Prujean. This collection, consisting originally of over 100 instruments, must have been of considerable value even at that period and the donor himself described it as "a precious storehouse of the art of the chirurgien." The donor, Dr. Thomas Prujean, was the son of Sir Francis Prujean, and was admitted a candidate for the Licentiate of the College of Physicians on April 4th, 1653, by his father, who was then President, and in commemoration of that event presented the case of instruments to the College on the same date. He was admitted as a Fellow in October, 1657, and died in October, 1662. Sir Francis Prujean, the father, was President of the College from 1650 to 1655, and is referred to in the diaries of both Pepys and Evelyn.

NEW PREPARATIONS

MELTIS "SIONON" CHOCOLATE.—Sionon is the trade name for D-sorbitol, a polyhedric alcohol closely related to the hexoses. In THE LANCET just two years ago Payne, Lawrence, and McCance stated their conclusion that while the quantity taken daily should not exceed 50 g. in divided doses (in view of the possibility of intestinal irritation) "Sionon can safely be used as a sweetening agent

* A full description of the surgical instruments exhibited was given in the *Medical Press and Circular* of Oct. 26th, 1927, by Mr. C. J. S. Thompson, hon. curator, historical section, museum of the Royal College of Surgeons of England.

for diabetics as it does not enter directly into carbohydrate metabolism." Acting on this favourable verdict Messrs. Meltis Ltd. (Keetons-road, London, S.E. 16) have produced a chocolate sweetened with sionon which is recommended for the use of diabetics and others whose sugar intake is restricted. It is sold in cartons holding forty napolitains, each of which is said to contain approximately: sionon, 1.0 gramme; milk-sugar and other carbohydrate, 1.0 g.; protein, 0.5 g.; and fat, 2.0 g. Judged as a sweetmeat the chocolate is of excellent quality, and to many palates the fact that it is not very sweet will seem an advantage. The carton bears the statement: "For diabetics—safe, palatable, nutritious."

CEROCOL.—Cerium oxalate has long been used for the relief of vomiting—especially the vomiting of pregnancy. As it is all but insoluble in water its action is generally held to be mechanical, resembling that of bismuth salts. Cerocol (distributed by Messrs. Coates and Cooper Ltd., 94, Clerkenwell-road, London, E.C. 1) is described as "a colloid-soluble form of cerium oxalate" which is "readily absorbed," and is held to have decided advantages over the form ordinarily prescribed. Prepared in small tablets, each containing 0.05 gramme of colloidal cerium oxalate, it is almost tasteless, and is said to be non-poisonous even in multiple doses. It is recommended, among other conditions, for vomiting from all causes, including sea and train sickness, and for nausea.

Vacancies

For further information refer to the advertisement columns

Aberdeen Royal Mental Hospital.—Sen. Asst. Physician.

Ashford Hospital, Kent.—Res. M.O. £150.

Battersea General Hospital, Battersea Park, S.W.—H.S. Also H.P. At rate of £130 and £120 respectively.

Benenden, Kent, National Sanatorium.—Jun. H.P. At rate of £150.

Birmingham Royal Cripples Hospital.—Res. H.S. At rate of £200.

Bradford, Royal Eye and Ear Hospital.—H.S. £160.

Brighton, Royal Alexandra Hospital for Sick Children.—H.P. £120.

Brighton, Sanatorium and Infectious Disease Hospital.—Jun. Res. M.O. At rate of £250.

Brighton, Sussex Eye Hospital, Eastern-road.—H.S. At rate of £150.

Bristol General Hospital.—Res. Surg. O. and Reg. £200. Also two H.P.'s, three H.S.'s, Res. Obstet. O., H.S. to Spec. Depts., also Cas. H.S. Each at rate of £80.

Chelsea Hospital for Women, Arthur-street, S.W.—Surgeon.

Chesterfield and North Derbyshire Royal Hospital.—H.S. to Ear, Nose, and Throat and Eye Depts. At rate of £150.

Children's Hospital, Hampstead, N.W.—Res. M.O. At rate of £150.

China, Mission Hospital.—Two Medical Men.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Res. M.O. £250. Also H.P. At rate of £100.

Coventry and Warwickshire Hospital.—Res. H.S. £125.

Denbigh County.—Deputy County M.O.H. and School M.O. £760.

Derbyshire Royal Infirmary.—Ophth. H.S. and Anaesthetist. £150.

Doncaster Royal Infirmary.—H.P. At rate of £175.

Eastern Hospital, Homerton-rose, E.—Med. Supt. £1100.

East Grinstead and District New Hospital.—Hon. Consultants to Special Depts.

Evelina Hospital for Sick Children, Southwark, S.E.—H.S. £120.

Exminster, Devon Mental Hospital.—Jun. Asst. M.O. and Pathologist. £350.

Glasgow, Lighthouse Joint Hospital, Shettleston.—Res. Physician. £350.

Hampshire County Council.—Asst. Tuberc. Officer. £700.

Hastings, Royal East Sussex Hospital.—Jun. H.S. At rate of £150.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Surg. Reg. £100.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. H.P. Also Res. H.S. Each at rate of £100.

Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Res. H.P. At rate of £100.

Huddersfield Royal Infirmary.—Res. Surg. O. £225-£250.

Ilford, West Ham Mental Hospital, Goodmayes.—Jun. Asst. M.O. £350.

Sanatorium.—Sen. Asst. Res. M.O. £125.

Consumption and Diseases of the Chest.—Asst. M.O. and Pathologist. £150.

Hospital, Great Ormond-street, W.C.—Asst. Physician for Diseases of Women, also Hon. Asst. Physician.

London Hospital, E.—Hon. Asst. Anaesthetist.

London Lock Hospital, 253, Harrow-road, W.—Res. M.O. for Male Depts. At rate of £175.

Manchester, Ancoats Hospital.—Asst. Pathologist. £300.

Manchester, Duchess of York Hospital for Babies.—Orthopaedic Registrar.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester Royal Infirmary.—Res. M.O. £200.

Manchester, St. Mary's Hospitals.—H.S.'s for Special Hospitals. Each at rate of £50.

Marie Curie Hospital, 2, Fitzjohn's-avenue, N.W.—Res. M.O. At rate of £100.

Miller General Hospital, Greenwich-road, S.E.—Refractionist. 52 guineas.

National Hospital for Diseases of the Nervous System, Queen-square, W.C.—Two H.P.'s. Each £150. Also Visiting M.O. for Convalescent Home.

National Temperance Hospital, Hampstead-road, N.W.—Cas. O. At rate of £120.

Nottingham General Hospital.—H.S. At rate of £150.

Oldham Royal Infirmary.—Cas. O. and H.S. and Physician. At rate of £175.

Oswestry, Robert Jones and Agnes Hunt Orthopaedic Hospital.—Res. Surg. O. £350.

Penshurst, Cassel Hospital for Functional Nervous Disorders, Swaylands.—Asst. Physician. £750.

St. Mary's Hospital, Marylebone-road, N.W.—H.P. £100.

Radium Institute, Riding House-street, W.—Asst. M.O. At rate of £250. Also H.S. At rate of £150.

Redhill, Reigate Institution, St. John's.—Res. Asst. M.O. At rate of £250.

Romford, Oldchurch Hospital.—Asst. Res. Surgeon. £500.

Royal Masonic Hospital, Ravenscourt Park, W.—Res. M.O. £300.

Royal Northern Hospital, Holloway, N.—H.S. At rate of £70. Also Hon. Radiologist.

St. Bartholomew's Hospital, E.C.—Physician.

St. John's Hospital, Lewisham, S.E.—H.S. At rate of £100.

St. Mary's Hospital, W.—Jun. Asst. Radiologist. £75.

St. Peter's Hospital for Stone, &c., Henrietta-street, W.C.—Clin. Asst.

Salford Royal Hospital.—H.S. At rate of £125.

Salisbury General Infirmary.—H.P. At rate of £125.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Radiologist.

Sheffield Royal Infirmary.—Clin. Asst. to Surgical Dept. At rate of £300.

Staffordshire General Infirmary.—H.P. and Cas. O. At rate of £150.

Stockport Infirmary.—H.P. £150.

Stoke-on-Trent, North Staffordshire Royal Infirmary.—Second H.P. At rate of £150.

Sunderland Royal Infirmary.—H.S. £120.

Surrey County Council.—Asst. M.O. £600.

Swansea General and Eye Hospital.—Res. Anaesthetist. £150.

Walsall County Borough.—Asst. M.O. £600.

West Bromwich and District General Hospital.—H.S. At rate of £200.

West London Hospital, Hammersmith-road, W.—Med. Reg. £250. Also H.P. and two H.S.'s. Each at rate of £100.

Westminster Hospital, Broad Sanctuary, S.W.—Obstet. Surgeon.

Weston-super-Mare General Hospital.—Res. H.S. £150.

Wickford, Essex, Runwell Hospital.—Deputy Med. Supt. £650.

Willersden General Hospital, Harlesden-road, N.W.—Res. Cas. O. At rate of £100. Also Hon. Clin. Assts. to Out-patient Depts.

Winchester, Royal Hampshire County Hospital.—Res. Surg. O. Also H.P. At rate of £200 and £125 respectively.

Windsor, King Edward VII. Hospital.—Three H.S.'s. Each at rate of £100.

Wolverhampton, New Cross Hospital and Institution.—Asst. Deputy M.O. £350.

Wolverhampton Royal Hospital.—H.S.'s. Each at rate of £100.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Chorley (Lancashire) and Abergavenny (Monmouth).

Births, Marriages, and Deaths

BIRTHS

CATER.—On Nov. 25th, the wife of Donald Cater, M.B. Camb., of the Lester Chinese Hospital, Shanghai, of a daughter.

MILBANK.—On Nov. 25th, at Bickley, the wife of Dr. R. J. Milbank, of a son.

MARRIAGES

MANSIE—KIRKPATRICK.—On Nov. 29th, at Belhaven Church, Glasgow, James Walker Mansie, M.R.C.S. Eng., L.D.S. R.C.S. Eng., of Putney, to Catherine Enid, second daughter of Mr. and Mrs. Duncan T. Kirkpatrick, of Glasgow.

PENNINGTON—COBB.—On Nov. 28th, at St. Paul's Church, Portman-square, London, Drury Pennington, M.B. Camb., to Ethel Margaret Cobb.

DEATHS

BOND.—On Dec. 2nd, suddenly, in Cheltenham, Lt.-Col. Richard Pratt Bond, R.A.M.C. ret'd., of Wood-ide, Copthorne, Sussex.

HATCH.—On Nov. 27th, at Cheltenham, Lieut.-Colonel William Keith Hatch, M.B. Aberd., F.R.C.S. Eng., Indian Medical Service (ret'd.).

WHITE.—On Nov. 28th, at Shrewsbury, Ernest William White, Lieutenant-Colonel, C.B.E., M.B. Lond., Emeritus Professor of Psychological Medicine, King's College, London.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

THE USE OF GONADOTROPIC HORMONES IN THE TREATMENT OF IMPERFECTLY MIGRATED TESTES

BY A. W. SPENCE, M.D. Camb., M.R.C.P. Lond.

FIRST ASSISTANT, MEDICAL UNIT, ST. BARTHOLOMEW'S
HOSPITAL; AND

E. F. SCOWEN, M.D., M.R.C.P. Lond.

SECOND ASSISTANT

In a previous communication¹ we reported results obtained in the treatment of 11 patients with imperfectly migrated testes by means of the gonadotropic hormones contained in the urine of pregnant women. We have now followed these patients for a fairly long period and are able to state our results in a total of 33 cases treated by this method. Our findings are such that we think hormone therapy deserves trial before surgical measures are undertaken.

EXPERIMENTAL STUDIES

The experimental work of Evans and his associates,^{2,3} Smith and Engle,⁴ Aschheim,⁵ and many others has shown that a gonad-stimulating principle is present in the anterior lobe of the pituitary, and that it controls the activity of the ovaries and testes. The evidence suggests that the hormone consists of two factors—one which brings about maturation, and one which causes luteinisation of the ovarian follicles. According to Smith,⁶ and Evans,⁷ the follicle-stimulating hormone is gametokinetic in that it stimulates both ova and the male germ cells, whereas the luteinising hormone acts principally on the connective tissue derivatives—the thecal cells of the ovaries and the interstitial cells of the testes. Large amounts of a gonadotropic principle, similar in action to that produced by the pituitary, were found by Aschheim and Zondek⁸ in the urine of pregnant women, and their pregnancy test depends on its presence. The effect produced by pregnancy urine extracts in the female is predominantly one of luteinisation and in the male of hypertrophy of the interstitial tissue of the testes. Collip and his collaborators⁹ do not consider that pregnancy urine extracts stimulate the seminiferous epithelium, but Smith and Leonard¹⁰ and Evans and his associates⁷ state that they induce spermatogenesis, a finding which is supported by the results obtained by Brosius¹¹ in the treatment of azoospermia by pregnancy urine extracts. The researches of Engle¹² have further shown that in immature monkeys, in which the testes are normally situated at the upper end of the inguinal canals, injections of extracts of anterior pituitary or of pregnancy urine bring about descent of the testes into the scrotum by the fourteenth day.

Clinical Findings

Of the 33 patients with imperfectly migrated testes treated with pregnancy urine extract in the present work, in 12 the maldescent was bilateral, in 4 unilateral with the other testis situated high in the neck of the scrotum, and in 15 unilateral with the other testis situated low in the scrotum, while in 2 the testes were situated high in the scrotum and were easily retracted. The ages of the patients ranged from 4 to 26 years, the majority being 11 to 14 years old.

The examination of the position of the testes was made with the patients standing up to avoid any retraction of a normally situated organ. Care was also taken to note the degree of mobility of the testis and whether it could be pushed through the external ring into the neck of the scrotum. The preparation of gonadotropic hormones used was Pregnyl, usually given in doses of 500 rat units* intramuscularly into the deltoid twice weekly. The administration of smaller doses with shorter intervals between each dose—e.g., five times per week—would probably be more efficacious, but in our experience this was impracticable in the treatment of these patients, who were necessarily out-patients.

A summary of the clinical findings and of the results of treatment is set out later, case by case, and summarised in Table I. In 6 of the 12 bilatera

TABLE I

Summarising the Results Obtained in the Hormone Treatment of Patients with Imperfectly Migrated Testes

BILATERAL CASES		
Descent of both testes.	Descent of one testis.	Failures.
Case 1 in 14½ mths.	Case 7 in 9 mths.	Case 11 after 7 mths.

CASES WITH TESTES IN UPPER SCROTUM

Descent of testis.
Case 32 in 2½ months.
" 33 " 3 "

cases, both testes descended into the scrotum within a period varying from 3 weeks to 14½ months.

Case 3 was that of a boy, aged 12, with Fröhlich's syndrome associated with bilaterally undescended testes; descent was brought about in 3 weeks, but the injections which were continued for several months had little or no effect on his general condition.

Case 1 was a bilateral cryptorchid aged 11, neither testis being palpable while he was under preliminary observation in the ward. At the end of 5 weeks' treatment the right testis was in the scrotum, and the left testis was in the scrotum at the end of 9 weeks. The scrotum, however, which was very small and retracted, remained so for many months, and the testes varied in position in spite of continued treatment with gonadotropic hormone. In view of the demonstration by Burrows¹⁴ that in mice the administration of oestrin produces inguinal hernia and relaxation of the muscle layers in this region, he was treated in addition with oestrin (Menformon) in doses of 2500 units intramuscularly twice weekly. The use of oestrin was continued for 2 months, but little if any effect was observed. It has been shown by Selye, Collip, and Thomson¹⁵ that after prolonged administration of gonadotropic hormone to virgin female rats the animals become insensitive to the stimulus, and that in spite of continued treatment the initial hypertrophy of the ovaries disappears and may even be replaced by atrophy. As the patient had received 9 months' treatment with gonado-

* A Janssen-Loefer rat unit of gonadotropic hormone is the least amount which will provoke oestrus in half of the animals injected with all necessary precautions.¹³

tropic hormone, it was possible that he had entered into a refractory phase. Therapy was therefore discontinued for 3 months. At the end of this time treatment with gonadotropic hormone was resumed for 2½ months, when the scrotum became quite lax and the testes remained low in the scrotum. At the present time, 2 months after cessation of treatment, the testes remain low in a normal scrotum.

In 4 of the bilateral cases descent of one testicle occurred after treatment for 5-9 months. In the remaining 2 bilateral cases descent has not been brought about after treatment for 7-9 months.

Of the 4 unilateral cases in whom the scrotal testis was situated in the upper scrotum, in 3 both testes were low in the scrotum at the end of 2 weeks, 2 months, and 5 months respectively. In the remaining case at the end of 7 months the scrotal testis was low in the scrotum, but the position of the inguinal testis remained unchanged. In the unilateral cases with the scrotal testis low in the scrotum, 8 were successful after 2 weeks' to 12 months' treatment and 7 unsuccessful after treatment for 5 to 9½ months. In the 2 cases in which the testis was situated in the upper scrotum and frequent retraction troubled the patient, the testis assumed a position low in the scrotum after 2½ and 3 months of treatment and retraction no longer occurred.

Thus in half the bilateral cases both testes descended, in one-third one descended, and in one-sixth descent has not yet taken place. Of the 19 unilateral cases a successful descent was brought about in 11 (58 per cent.). Of the total 33 cases there have been 10 failures (30 per cent.).

We have been able to follow up the early cases after cessation of treatment. It is our custom to ask patients to present themselves at hospital every one, two, or three months after they have discontinued treatment. In 9 out of 11 such cases (3 bilateral and 6 unilateral) the testes are still in the scrotum 1-11 months after treatment was stopped. In 1 bilateral case one testis has retracted into the inguinal canal after 1 month without treatment, and in 1 unilateral case the position of the testis varies 10 months after treatment (Table II.).

TABLE II

Summarising the Follow-up of 11 Cases after Cessation of Treatment

TESTES REMAINED IN SCROTUM			
Case 1 (bilateral)	} after cessation of treatment for	2 months.

RETRACTION INTO INGUINAL CANAL			
Case 2 (bilateral) after cessation of treatment for 1 month (retraction of one testis).			
" 18 (unilateral) after cessation of treatment for 10 months (position varies).			

COMPLICATIONS OF TREATMENT

After the first, and sometimes also after the second injection, in a considerable number of cases there has been a local reaction consisting of pain, redness, and swelling round the site of the injection. This has even been severe enough to prevent the patient from using his arm next day, but as a rule it has disappeared by the second or third day. Reactions were not observed after subsequent injections, provided that the same site was used. If a different site was chosen, it was not unusual to produce some local reaction. Occasionally a slight reaction was observed locally

TABLE III.—CASES TREATED

Case.	Age in years and initial condition.	Result.
1	11. Bilateral. Testes not palpable. Scrotum retracted.	After 5 wks. right testis low in scrotum; after 9 wks. left low in scrotum. Positions later varied in spite of continued treatment. After 6 mths. menformon 2500 units given in addition intramuscularly twice weekly for 2 mths. Treatment with pregnyl continued for 9 mths. No change in condition. Treatment stopped for 3 mths.; pregnyl injections then resumed for 2½ mths. At the end of this period both testes low in scrotum and scrotum lax. After 2 mths. without treatment, testes low in scrotum and scrotum normal.
2	10½. Bilateral; 1 year before, right orchidopexy. Right testis now at external ring; left in inguinal canal and cannot be pushed into scrotum.	After 4 mths. right testis low in scrotum, left at external ring and can be pushed into scrotum. Later position of right varied. After 10 mths., both low in scrotum. After 11 mths., treatment stopped; 1 mth. later right testis in mid-scrotum; left in inguinal canal. According to patient, position varies, but both testes usually in scrotum.
3	12. Fröhlich's syndrome with bilaterally undescended testes.	After 3 wks. both testes in scrotum. Treatment continued for 2 mths. General condition unchanged.
4	12. Bilateral; 1 year before, left orchidopexy. Now left testis in inguinal canal and cannot be pushed into scrotum. Right in inguinal canal and easily pushed into scrotum.	After 2 wks. right testis low in scrotum. After 5 mths. both testes low in scrotum. Treatment continued for 7 mths. After 6 mths. without treatment both testes low in scrotum.
5	10. Bilateral. Both testes in inguinal canals; right can be pushed into neck of scrotum, left cannot.	After 2 wks. right testis in scrotum. After 4 wks. both low in scrotum. Treatment continued for 2 mths. After 4 mths. without treatment, testes varied in position. Treatment recontinued for 2 mths. After further 4 mths. without treatment, testes low in scrotum.
6	4. Bilateral. Right testis in inguinal canal, and cannot be pushed into scrotum. Left not palpable.	After 5 wks. left testis low in scrotum, right in upper scrotum. After 2 mths. both low in scrotum, but position varies. After 7 mths. both low in scrotum.
7	14. Bilateral. Left orchidopexy previously. Now left testis in neck of scrotum, right in inguinal canal and cannot be pushed into scrotum.	After 3 mths. left testis low in scrotum. After 9 mths. right testis still in inguinal canal.
8	8½. Bilateral. Both in inguinal canals and cannot be pushed into scrotum.	After 4 mths. right testis in mid-scrotum; right inguinal hernia. After 5 mths. left still in inguinal canal.
9	11. Bilateral. Both testes in inguinal canals and cannot be pushed into scrotum. Left inguinal hernia. Scrotum retracted.	After 2 mths. right testis in scrotum. After 7 mths. right low in scrotum; position of left unchanged.
10	10. Bilateral. Both testes in inguinal canals, very small, cannot be pushed into scrotum.	After 3 mths. right testis in mid-scrotum, left at external ring and easily pushed into scrotum. After 5 mths. right low in scrotum; position of left unchanged.
11	13. Bilateral. Both testes in inguinal canals and cannot be pushed into scrotum.	After 7 mths. no change in condition.
12	5. Bilateral. Both testes in inguinal canals and cannot be pushed into scrotum.	After 7 mths. both testes at external ring and can be brought into scrotum. After 9 mths. condition unchanged.

TABLE III.—(continued)

Case.	Age in years and initial condition.	Result.
13	14. Unilateral. Left testis small and in upper scrotum. Right testis small, in inguinal canal and cannot be pushed into scrotum.	After 2 wks. both testes low in scrotum and normal in size.
14	12. Unilateral. Right testis small, in upper scrotum and easily retracted into inguinal canal. Left in inguinal canal and cannot be pushed into scrotum.	After 2½ mths. right testis low in scrotum, left in upper scrotum. Left inguinal hernia. After 5 mths. both low in scrotum.
15	13. Unilateral. Left testis in inguinal canal; right in upper scrotum and easily retracted.	After 1 mth. left testis low in scrotum, right in mid-scrotum. After 2 mths. both low in scrotum. After 1 mth. without treatment both low in scrotum.
16	14½. Unilateral. Right testis in inguinal canal and cannot be pushed into scrotum. Left in upper scrotum and occasionally in inguinal canal.	After 7 mths. left testis low in scrotum, right in inguinal canal.
17	8. Unilateral. Right testis in inguinal canal and cannot be pushed into scrotum.	After 5 wks. right testis in neck of scrotum. Position then varied. After 3 mths. remained in upper scrotum; small right inguinal hernia now present. After 6 mths. injections discontinued; 5 mths. after cessation of treatment testis still in upper scrotum; treatment recontinued for 1 mth.; 3 mths. later testis still in upper scrotum.
18	8. Unilateral. Left testis in inguinal canal and easily pushed into scrotum. Right testis in scrotum and easily pushed into inguinal canal. Scrotum retracted.	After 2 wks. left testis in scrotum; position then varied. After 6 wks. left testis remained low in scrotum; treatment continued for 3 mths. After 10 mths. without treatment neither testis in scrotum, but both can be brought easily into scrotum. Parent says position varies.
19	13½. Unilateral. Right testis in inguinal canal and cannot be pushed into scrotum.	After 2 wks. right testis in mid-scrotum. Treatment continued for 2½ mths. After 11 mths. without treatment right testis still in scrotum.
20	14. Unilateral. Right testis in inguinal canal and cannot be pushed into scrotum. Testis small.	After 2 mths. right testis in upper scrotum; small right inguinal hernia. After 12 mths. treatment with interval of 1 mth., right testis still in upper scrotum. Testis small.
21	15½. Unilateral. Right testis in external ring and can be brought through into neck of scrotum.	After 4 mths. right testis in mid-scrotum. After 6 mths. testis still in mid-scrotum. After 1 mth. without treatment testis still in mid-scrotum.
22	13. Unilateral. Left testis in inguinal canal and easily pushed into scrotum. Scrotum retracted.	After 5½ months left testis in mid-scrotum. Did not attend regularly for treatment.
23	18. Unilateral. Right testis in inguinal canal and cannot be pushed into scrotum.	After 2 mths. right testis in mid-scrotum. After 2½ mths. difficult to push testis into inguinal canal; treatment stopped. After 10 mths. without treatment right testis still in scrotum.
24	5½. Unilateral. Right testis in inguinal canal and cannot be pushed into scrotum. Left easily retracted.	After 3 wks. right testis in upper scrotum. Treatment discontinued for 3 mths. owing to patient's absence from England. On return scrotum empty, both testes in inguinal canals. Left easily pushed into scrotum. After 6 wks. left in scrotum, right in neck of scrotum.

TABLE III.—(continued)

Case.	Age in years and initial condition.	Result.
25	13. Unilateral. Right testis in inguinal canal and cannot be pushed into scrotum.	After 8 mths. testis just above external ring.
26	12. Unilateral. Left testis in inguinal canal and cannot be pushed into scrotum. Right testis small.	After 6 mths. left testis still in inguinal canal, but can easily be pushed into lower scrotum. After 9½ mths. position unchanged. Right testis increased in size.
27	12. Unilateral. Left testis not palpable. Right congenital hydrocele.	After 7 mths. condition unchanged.
28	13. Unilateral. Left testis not palpable. Small left inguinal hernia.	After 7 mths. condition unchanged.
29	13½. Unilateral. Left testis not palpable. Small left inguinal hernia.	After 5 mths. condition unchanged.
30	13. Unilateral. Left testis in inguinal canal and cannot be pushed into scrotum. Right inguinal hernia.	After 5 mths. left testis still in inguinal canal, but can be pushed into scrotum. Small left inguinal hernia.
31	23. Unilateral. Right testis at external ring; lower pole can be pushed into scrotum.	After 2 mths. position unchanged, but testis can be pushed into neck of scrotum. After 5 mths. condition unchanged.
32	12½. Both testes in scrotum but retract easily into inguinal canals.	After 2½ mths. treatment no further retraction. After 3 mths. without treatment no retraction.
33	26. Right testis in upper scrotum and easily retracted, especially when patient is lifting heavy objects.	After 1 mth. testis no longer retracts. After 3 mths. testis in mid-scrotum.

when a fresh sample of gonadotropic hormone was used. In 2 cases, after the first injection only, there was a general reaction, consisting of malaise, anorexia, nausea, and headache. This came on the day after the injection and incapacitated the patient for that day only.

There is a frequent association of inguinal hernia with the condition of imperfect migration of the testis and we have carefully examined each patient with this consideration in mind. In 4 cases a hernia was present before beginning treatment; in 5 other cases a hernia became obvious during the course of treatment. It seems highly probable that the hernia was present from the beginning and only became noticeable as the testis descended, the hernial sac presumably descending with the testis.

In several cases there has been some enlargement of the testes during treatment, and in a few slight enlargement of the penis and growth of the pubic hair—an effect ascribed to stimulation of the interstitial cells of the testes (Table III.).

Discussion

Gonadotropic extract of pregnancy urine has now been used by several investigators in the treatment of imperfectly migrated testes. The first was Schapiro¹⁶ who in 1930 treated 13 cryptorchids, in all of whom the testes descended into the scrotum

more or less completely. Since then successful results have been reported by Goldman and Stern,¹⁷ Kunstader and Robins,¹⁸ Sexton,¹⁹ Rubinstein,²⁰ Aberle and Jenkins,²¹ Brosius,²² and Webster.²³

The criticism which may be levelled at the results claimed is that the testes sometimes descend spontaneously by the time of puberty. For instance, Drake²³ has reported that 24 of 38 undescended testes came down while under observation for several years at ages ranging from 10 years to 16 in one case, amounting to 37 per cent. in whom spontaneous descent failed to take place, compared with 30 per cent. of failures in our treated cases. This, however, is the highest incidence of spontaneous descent which we have been able to find recorded and it is significant that the percentage of failures in our treated cases is smaller. We feel that it is more than a coincidence that so many of our cases responded during treatment, and that arguments in favour of the specific action of gonadotropic hormones in this respect are: (1) in 4 cases (Nos. 2, 5, 18, and 24), in which the testes descended into the scrotum during treatment, retraction of the testes into the inguinal canal occurred after treatment was discontinued; (2) in 2 bilateral cases (Nos. 2 and 4), in which an orchidopexy on one side had previously been performed, the testis subsequently retracted into the inguinal canal but descended into the scrotum again during hormone treatment; (3) a successful result was obtained in 2½ months in a patient aged 18 (Case 24), in whom spontaneous descent is highly improbable.

The mode of action of the gonadotropic hormones in bringing about testicular descent is unknown. It has been suggested by Engle¹² that they may be involved in the intra-uterine descent of the testes, as they are present in the maternal circulation throughout the period of gestation. It is postulated that maldescent may be due to inability of the testes at that time to respond to the stimulus.

In the hormone treatment of undescended testes there appears to be no hard-and-fast rule as to which type of case will be successful. Descent of both testes into the scrotum has been obtained in cryptorchids in whom the testes were situated in the abdominal cavity, and also in cases of inguinal testes which could not be brought into the scrotum on manipulation. We have observed however that in the few cases in which the testis could be pushed into the scrotum an early response was obtained. The treatment is also of advantage in those cases in whom the testes are situated high up in the scrotum and give rise to pain or discomfort due to retraction into the inguinal canal on exertion. Failure is obvious in cases of ectopic testis, and descent will not take place in cases of abdominal testes which do not engage at the internal ring, or of inguinal testes which are held up by adhesions. In cases which do not respond to treatment and require operation subsequently, the administration of gonadotropic hormones before and for some time after operation may be of advantage in ensuring against any likelihood of postoperative retraction into the inguinal canal.

In the treatment of refractory cases it should be borne in mind that after prolonged administration of gonadotropic hormone there ensues a phase in which there is loss of sensitivity to the stimulus, as evidenced by the experimental work of Selye, Collip, and Thomson quoted above. For this reason it is advisable to discontinue treatment after 6-9 months and to resume it after an interval of 3 months,

when it is probable that sensitivity has returned. In this manner the possible occurrence of atrophy of the gonads, which these authors found in some of their experimental animals treated for a long time, is prevented.

Summary

Thirty-three patients, aged 4 to 26 years, with imperfectly migrated testes have been treated with the gonadotropic hormones of pregnancy urine (pregnynl), given in doses of 500 rat units intramuscularly twice a week. Both testes descended into the scrotum in 6 of the bilateral cases and one testis in 4, while in 2 cases descent has not occurred. In 11 out of 19 unilateral cases the testis descended, and in 2 cases with the testis high in the neck of the scrotum it assumed a position low in the scrotum. Successful results were obtained within periods ranging from 2 weeks to 14½ months. The testes have remained in the scrotum in 9 out of 11 cases followed for 1-11 months after cessation of treatment.

We wish to thank the physicians and surgeons of St. Bartholomew's Hospital and elsewhere who have kindly referred these cases to us. One of us (A. W. S.) acknowledges with thanks personal and expenses grants from the Medical Research Council. We are indebted to Dr. A. X. Macbeth, of the Organon Laboratories, for generous supplies of pregnynl.

CONFERENCE ON ATMOSPHERIC POLLUTION.

Thirty-eight representatives of local authorities and other organisations met on Nov. 25th in half-yearly conference at the offices of the Department of Scientific and Industrial Research to receive a report from Dr. G. M. B. Dobson, F.R.S., chairman of the Atmospheric Pollution Research Committee, on the progress of recent researches. A number of offers to undertake additional investigations and observations were received. Mr. J. W. Beaumont, of Halifax, reported upon the analysis of atmospheric dust samples collected in Leeds, Halifax, and Huddersfield. Representatives of the London County Council mooted the desirability of reviewing measures to obviate the emission of soot, ash, grit, and gritty particles from chimneys such as those of electric power stations. Other local authorities emphasised the need of wider remedial measures for combating pollution. The conference appointed a small committee to put forward concrete proposals for the application of such measures by industry and to devise a scheme of financial coöperation.

BOVINE PHTHISIS

ITS INCIDENCE IN NORTH-EAST SCOTLAND

COUNTY CASES

By A. STANLEY GRIFFITH, M.D. Vict., Ph.D. Camb.

MEMBER OF THE SCIENTIFIC STAFF, MEDICAL RESEARCH COUNCIL; AND

J. SMITH, M.D., D.Sc. Aberd., M.R.C.P. Lond., D.P.H.

REGIONAL BACTERIOLOGIST, CITY HOSPITAL LABORATORY, ABERDEEN

THE investigations of Dr. W. T. Munro, Glenlomond Sanatorium, first directed attention to the relatively frequent occurrence in Scotland of phthisis pulmonalis due to bovine bacilli. In the period 1923-30 he obtained cultures of tubercle bacilli from the sputum of 366 phthisical persons, most of them resident in the middle east of Scotland, and found that 15 were of bovine and 350 were of human type, and I was a mixture of these two types. In 1931 Dr. Munro and one of us (A. S. G.) extended the inquiry to the southern counties of Scotland. The results showed that in this part of Scotland also phthisis pulmonalis was caused by bovine bacilli with about the same relative frequency as in the middle east of Scotland. Associated in these districts with this unusual frequency of bovine phthisis there was a high percentage of bovine infections in other forms of human tuberculosis. For example, about a third of the cases of tuberculous meningitis and approximately a third of bone and joint tuberculosis could be attributed to infection with bovine tubercle bacilli. On the other hand in England, taken as a whole, the percentage frequency of bovine infections was less than in Scotland, both in the non-pulmonary and in the pulmonary forms of the disease. These results suggest that the incidence of bovine phthisis in a country varies with that of non-pulmonary tuberculosis of bovine origin, and that where the proportion of bovine infections in the latter forms of the disease is high there phthisis of bovine origin will also show a rise.

In order to test this hypothesis and at the same time to ascertain the percentage incidence of bovine phthisis in a new district we have undertaken a bacteriological investigation of phthisis pulmonalis in north-east Scotland.

This district is particularly suitable for such an inquiry, since recent investigations have shown that a relatively large proportion of the cases of non-pulmonary tuberculosis admitted to hospital in the

TABLE I

Form of tuberculosis.	No. of cases.	Human.	Bovine.
Meningitis ..	6	3 (13, 14, 27)	3 (1, 13, 61)

Renal ..	7	4 (20, 40, 47, 52)	3 (11, 23, 27)
Bone and joint	9	7 (6, 14, 15, 21, 37, 38, 64)	2 (4, 25)
Cervical gland	5	4 (12, 21, 36, 62)	1 (10)
	30	20	10

The figures in parentheses are the ages of the patients.

city of Aberdeen are infected with bovine tubercle bacilli. The investigations to which we refer were begun in 1933 and were limited at first to cases of tuberculous meningitis. The results in 15 cases were reported in 1934; of these 8 were due to human and 7 to bovine bacilli; 12 of the cases (6 human and 6 bovine infections) were in persons resident in the city. In 1934 the investigations were extended

to include all forms of non-pulmonary tuberculosis, of which 30 cases have since been examined. The results are summarised in Table I.

Of the 30 cases 6 were of tuberculous meningitis, and it is interesting that as in the first series of meningitis cases from Aberdeen the proportion of human and bovine infections was equal. The ratio of human to bovine infections in the cases of cervical gland and bone and joint tuberculosis is less than in other Scottish series, and thus we attribute to the fact that the patients were mainly adolescent and adult. Of the 30 cases 14 occurred in children under sixteen years of age, and of these 7 were bovine and 7 were human infections. Among the 16 adults there were 3, 1 with spinal and 2 with renal tuberculosis, who were infected with bovine bacilli.

Results with Pulmonary Tuberculosis

The present inquiry was begun in April, 1934, and was in the first instance restricted to county cases of pulmonary tuberculosis—that is to say, cases from the rural districts and small towns of north-east Scotland chiefly of the counties of Aberdeen, Banff, and Moray. We have now completed the investigation of 103 cases and as a relatively high proportion of these has yielded bovine bacilli we think it desirable at this stage to publish an interim report of our results. We are indebted to Dr. H. J. Rae, chief regional medical officer, to Dr. G. S. Banks, regional tuberculosis officer, to the medical officers of health of other authorities, and to very many medical practitioners for their courtesy and kindness in supplying specimens and information.

The typing of the strains was done by one of us at the Field Laboratories, Cambridge. In all but one instance the cultures were raised directly from the sputum with the aid of potassium hydroxide.

The method was as follows: equal parts of the sputum and 5 per cent. KOH were thoroughly mixed and incubated for $\frac{1}{2}$ to $\frac{3}{4}$ hour at 37°C. A small quantity was then spread evenly over the surface of coagulated egg, from 3 to 4 tubes—one of 5 per cent. glycerin egg and the rest of plain egg—being sown. With one specimen of sputum the direct cultures failed owing to a spore-bearing contaminant, and in this instance recourse was had to the guinea-pig. After from 3 to 4 weeks' incubation the tubes were examined and a provisional diagnosis of type was made on the characters of the primary colonies. If in primary culture on egg and subsequently in subculture on glycerinated potato the cultural characters were those of the eugonic human tubercle bacillus the strain was not tested as to its virulence. On the other hand, all the strains which were dysgonic on egg in primary culture or proved dysgonic on glycerinated potato in subculture were tested as to their virulence for animals.

The cultures obtained from the 103 cases fell into the three following groups: dysgonic bovine, dysgonic human, and eugonic human.

CASES WITH BOVINE BACILLI IN THE SPUTUM

Tubercle bacilli of the bovine type were cultivated from the sputum of 13 of the cases. Except in one case (C.S. 37) where the patient died before there was any suspicion that the infection was bovine all these cases were examined twice and one was examined three times, the intervals between the specimens ranging from 23 to 128 days. The total number of strains from the 13 cases was therefore 26. All the strains were typically dysgonic bovine in cultural characteristics and none showed any sign of the presence in them of eugonic human tubercle bacilli. Each of the 26 strains was tested on the rabbit, 12 strains from 10 cases by intravenous and

* A sister, aged 19, died of pulmonary tuberculosis in 1931. A brother (aged 20) and a sister (aged 18) had neck glands excised at 7 years (1921) and 4 years (1920) respectively.

19 strains from 13 cases by subcutaneous inoculation. Twelve rabbits were injected intravenously with 0.01 mg. of culture or less; they died of typical severe general tuberculosis in from 16 to 59 days. Nineteen rabbits were injected subcutaneously with 10 mg. or less; one died in 34½ days and showed moderate general tuberculosis; the remainder died in from 35 to 91 days (average 64.1 days) of severe general tuberculosis typical of infections with bovine bacilli.

In 5 of the 13 cases there was a history of previous glandular tuberculosis. Four of these patients had suffered from tuberculous cervical adenitis, three (S. 2, C.S. 19, C.S. 80) in childhood, and one (C.S. 94) in adolescence. The fifth patient (C.S. 26) was found during an exploratory abdominal operation five years ago (by Dr. Alec Robertson) to have large glandular masses in the abdomen. There is little doubt that in these 5 cases the channel of entry of the bovine bacilli was the alimentary canal. In 8 of the 13 cases there was no past history and no present evidence of glandular enlargements. Four of the 8 have been radiographed but none showed calcareous abdominal glands. The question therefore arises whether any of these persons could have been infected by inhalation of bovine bacilli discharged either from tuberculous cattle, and suspended as dust in the air of shippens or byres, or from human beings suffering from bovine phthisis.

None of the 8 persons however, so far as could be ascertained, had ever come into direct contact with cattle and 3 of them were the only clinically tuberculous members of their families. On the other hand, 5 of the 8 persons had been in contact with a relative or relatives suffering from pulmonary tuberculosis. In one case the infected relative was the husband, in another a sister, in another a paternal uncle, in a fourth (C.S. 28) a paternal uncle and two maternal aunts. All these relatives had died of pulmonary tuberculosis some time before our inquiry began. In the remaining case (S. 3) the mother showed X ray evidence of old healed tuberculosis of

the lungs. We were unable therefore to ascertain whether any of these 5 cases might have been infected with bovine bacilli from a human source. The possibility of extra-familial infection with bovine bacilli may, we think, be excluded as no other cases of bovine phthisis were found in any of the localities in which a bovine case occurred.

The further histories of 12 of the 13 patients since the bacteriological investigations are as follows: the condition of five of the patients (S. 2, S. 3, C.S. 19, C.S. 94, and C.S. 103) has improved under treatment, though the prognosis in one is doubtful. In two (C.S. 9 and C.S. 28) the general condition is fairly good but the disease is slowly progressing. In three (C.S. 26, C.S. 45, and C.S. 102) the disease is steadily progressing and the prognosis is bad; one of these (C.S. 102) has diabetes. Two of the patients (C.S. 37 and C.S. 80) have died but an autopsy was not made in either case.

The duration of clinical tuberculosis when sputum was taken for examination ranged from a few months to nine years. In 4 of the 5 cases with previous glandular tuberculosis the intervals between the first infection and clinical signs of pulmonary tuberculosis ranged from about 2 to 12 years, while in the fifth the interval could not be ascertained.

CASES WITH TUBERCLE BACILLI OF THE HUMAN TYPE IN THE SPUTUM

Cultures belonging to the human group of tubercle bacilli were obtained from 90 persons, of whom 45 were males and 45 were females. The ages of the patients ranged from nine to seventy-seven years, but only 8 were under twenty and 15 over fifty years of age. Of the 90 patients 25 were in employment or had been employed as farm servants.

The strains from 85 of the cases produced on the various differential media the luxuriant growths of the eugonic human type of tubercle bacillus. The strains from the remaining 5 were eugonic on egg and glycerin egg and dysgonic on glycerinated potato.

The virulence of each of these five strains was tested on the rabbit by intravenous inoculation and on the guinea-pig by subcutaneous inoculation, the dose of culture for each animal being 0.1 mg. One rabbit died of tuberculosis in 98 days; four rabbits were killed in from 71 to 138 days, and showed slight to moderate generalised tuberculosis. The tuberculous lesions in the five rabbits were similar in appearance and distribution to those which follow intravenous inoculation of eugonic human bacilli in equivalent dose. The guinea-pigs died in from 19 to 53 days, and showed general tuberculosis. The lesions were slight in two guinea-pigs which died prematurely, and of only moderate severity in the remaining three. The characters and virulence of the 5 strains were therefore those of the dysgonic human type of tubercle bacillus. In order to ascertain whether or not the bacilli in such cases are always of the dysgonic human type a further sample of sputum from each of two of the patients was examined bacteriologically after intervals of 9 and 7½ months respectively. The cultures were identical in cultural characters with those first isolated.

MICROSCOPICAL APPEARANCES OF THE TUBERCLE BACILLI IN THE SPUTUM

After determining the types of the tubercle bacilli in the 103 cases of pulmonary tuberculosis the records of the numbers and microscopical characters of the tubercle bacilli in the specimens of sputum were analysed.

Bovine bacilli (13 cases).—In 2 instances the tubercle bacilli were scanty, in 6 moderately numerous, in 3 numerous, and in 2 very numerous. In 10 of the 13 cases the bacilli were predominantly short and uniformly stained, and only few were of medium length and beaded. In the remaining 3 cases the bacilli varied in length but were for the most part of moderate length, beaded, and curved and indistinguishable from ordinary tubercle bacilli of human type.

TABLE III.—GIVING REGIONAL DISTRIBUTION OF BOVINE CASES

County.	No. of cases.	Eugonic human.	Dysgonic human.	Bovine.	Percentage bovine.
Aberdeen ..	46	36	3	7	15.2
Banff ..	22	18	..	4	18.2
Moray ..	8	6	..	2	25.0
Kincardine ..	7	7	..	..	0.0
Caithness ..	4	2	..	..	0.0
Inverness ..	1	1	..	..	0.0
Sutherland ..	1	1	..	..	0.0
Nairn ..	1	1	..	..	0.0
Shetland ..	9	9	..	..	0.0
Orkney ..	3	2	1	..	0.0
—	103	86	4	13	12.6*

* Or 14.3 on the mainland.

Human bacilli (90 cases).—In 1 specimen no tubercle bacilli were found microscopically. In 4 specimens bacilli were scanty, and in 68 they were moderately, in 12 very, and in 5 extremely numerous. The microscopical appearance of the bacilli showed some variation. In 67 instances the bacilli were described as being of ordinary human type—that is to say, they were beaded or vacuolated, curved or bent, and predominantly of good length. In 21 instances a considerable proportion of the bacilli were notably short, the rest being ordinary beaded forms. In some instances the short forms were uniformly stained, and it was thought at the time that the bacilli might turn out to be bovine but this inference proved to be incorrect. In the other instances the short forms tended to beadedness, and uniformly stained forms were not conspicuous.

Discussion

This series of cases of pulmonary tuberculosis from north-east Scotland has yielded the highest percentage of bovine infections yet recorded for this form of human tuberculosis. An analysis of the

cases according to their counties of origin shows that all the bovine cases were derived from three counties—namely, those of Aberdeen, Banff, and Moray—giving bovine percentages of 15, 18, and 25 for the counties respectively, and 17.1 for the three counties together. This last percentage is more than three times as high as that (nearly 5.0 per cent.) ascertained by Munro and Griffith for the rest of Scotland.

It is important to consider the origin of these cases and the cause of the exceptionally high incidence of bovine infections in pulmonary tuberculosis in the north-east of Scotland. There is now no doubt that the principal source of bovine bacilli in human tuberculosis is the milk of tuberculous cows and from clinical evidence we have concluded that 5 of our cases were infected through this agency. In the remaining 8 cases we have not obtained any evidence—either clinical or pathological—that the infection was primarily alimentary. The absence of clinical evidence of tuberculous infection by ingestion does not however necessarily exclude the alimentary canal as the portal of entry of the bacilli and in some of the cases they may have entered through the intestinal mucous membrane as occurred in several similar instances already reported where calcareous mesenteric glands were found on autopsy or, as in four recently discovered cases, were seen on radiological examination.

As we have had to do with strictly rural areas in which many of the inhabitants are employed on farms the possibility of infection through inhalation of infected dust in shippens, &c., has been considered. Only one of the persons with bovine bacilli in the sputum, however, had worked on a farm, and she had suffered from cervical adenitis in childhood and was therefore probably infected through milk.

The presence in a community of cases of bovine phthisis pulmonalis introduces the possibility of infection with bovine bacilli through the agency of human sputum. In this series we have no bacteriological evidence that such transmission might have occurred as, although in five of the families there was a history of tuberculosis in other members, no material, for reasons previously stated, was available for investigation.

Without taking account of any of the cases in which the source of the bacilli was undetermined we find that more than 6.5 per cent. of the bovine phthisis cases from the counties of Aberdeen, Banff, and Moray were of alimentary origin. This shows a greater relative frequency of bovine phthisis of alimentary origin in north-east than in the rest of Scotland, and one may ask whether the opportunities of infection through milk are more abundant in these counties than in other parts of the country.

In considering this question it must be remembered that in the alimentary cases the dates of infection with bovine bacilli were long anterior to the appearance of clinical signs of pulmonary tuberculosis which also had been in existence for varying periods before the bacteriological investigations were made. There are no records relating to the incidence of tuberculosis in cattle so far back. We do not know accurately even at the present day the extent to which cattle in the north-east of Scotland are infected with tuberculosis, but judging from the results of milk testing the degree of infection in milk sent to Aberdeen does not appear to be greater than in that delivered to the other principal cities of Scotland.

Can the high incidence of bovine pulmonary tuberculosis be correlated with a greater consumption

of milk in these counties? In 1934 the results of an inquiry into the average amount of liquid milk consumed in Scottish households were published by the Department of Health for Scotland. The investigation revealed that the consumption of milk varies greatly in different localities and is highest in the region—which includes the area we are investigating—north of the industrial belt of Scotland. In this region the average daily consumption per head of the population of all the counties together exceeds 0·8 pint, the county of Aberdeen having the highest consumption—namely, 1·03 pint per head. There is therefore in these counties a definite relationship between the amount of milk consumed and the incidence of bovine infections in human beings. In this connexion we may mention that 12 of the patients with bovine bacilli in the sputum had been in the habit all their lives of taking raw milk as a beverage and with porridge while the remaining one developed cervical adenitis in childhood and did not consume much in adolescent or adult life owing to his occupation as marine engineer. It is, we think, to the national custom of taking untreated uncertified milk with porridge, fruit, &c., and at other times, that the exceptional frequency of bovine infections in Scotland is to be attributed.

The relatively large proportion of bovine infections found in this series of phthisis cases may be in part fortuitous—due to a chance grouping of cases which owed their origin to infections acquired in different years—and comparable with the experience of Munro in the year 1927–28, when as many as seven of the cases of pulmonary tuberculosis admitted in that year to Glenlomond Sanatorium were found to be infected with bovine bacilli. To illustrate how such a grouping of cases might come about we may mention that in the cases preceded by glandular tuberculosis the intervals between infection and clinical signs of pulmonary tuberculosis ranged from about 2 to 12 years.

To what extent the high percentage of bovine infections in this series was the result of chance grouping can be determined only by the systematic investigation in these counties of all existing cases of pulmonary tuberculosis and of those which arise during a succession of years. We are continuing our investigations on these lines.

SUMMARY

(1) The types of tubercle bacilli have been determined in the sputum of 103 cases of phthisis pulmonalis from the rural and small urban districts of north-east Scotland, including the Orkney and Shetland Isles. (2) The tubercle bacilli were of the human type in 90 cases (85 eugonic and 5 dysgonic), and of the bovine type in 13 cases. (3) All the 26 strains obtained from the 13 bovine cases were typically dysgonic and highly virulent for rabbits. (4) Of the 13 bovine cases 7 were derived from the county of Aberdeen (15·2 per cent. of 46 cases), 4 from the county of Banff (18·2 per cent. of 22 cases), and 2 from the county of Moray (25·0 per cent. of 8 cases). (5) Twelve cases from the counties of Kincardine, Caithness, and Sutherland, and 12 from the Orkney and Shetland Isles yielded tubercle bacilli of the human type only.

DEVIZES AND DISTRICT HOSPITAL.—Sir Ernest Wills, lord-lieutenant of Wiltshire, has opened a £23,000 extension to this hospital, which provides six private wards, two public wards, and an isolation block. All but £1600 of the money required had been raised and this amount was reduced by a donation of £100 from Sir Ernest Wills.

AMIDOPYRIN HYPERSENSITIVITY AND AGRANULOCYTOSIS *

By A. BUUS HANSEN

ASSISTANT PHYSICIAN, AALBORG COUNTY HOSPITAL, DENMARK; AND

C. HOLTEN, M.D.

CHIEF PHYSICIAN AT THE HOSPITAL

THE first hint that amidopyrin is a cause of agranulocytosis was the recognition of a number of cases whose only common factor was that the patients had been taking this drug. Madison and Squier¹ in the United States observed 14 such cases in succession, and we² had 6 in the course of two years in the medical department of the Aalborg County Hospital. The latter developed in hospital in patients who were being treated for entirely different diseases, and all they had in common was that they had been given amidopyrin, its use being continued until after agranulocytosis appeared.

These observations have given rise to a long series of communications from America, Holland, and Scandinavia, and it has been shown that a large proportion of agranulocytosis patients have taken amidopyrin or medicine containing it. Plum³ collected 41 cases of amidopyrin agranulocytosis, with 37 deaths, which occurred in Denmark between May, 1933, and July, 1934. On referring also to the clinical notes of cases treated before the rôle of amidopyrin was recognised, it is possible to show that some of these patients had had this drug, but information about the drugs employed is apt to be incomplete. Often it is hard to get straightforward information even from the patient—partly because neither doctors nor the public think it of much importance which antineuralgic remedy is given and partly because amidopyrin forms part of preparations bearing other names. The cases in which the disease has developed in hospital seem to us to provide the best grounds for holding the drug responsible.

Although amidopyrin has been used in very large quantities, agranulocytosis is rare; and this suggests that we are not dealing with an ordinary intoxication, but with a state of hypersensitivity—an allergic phenomenon. The mortality is high, approximating to 90 per cent., and hence experiments to demonstrate hypersensitivity have not been numerous. But a fair number have now accumulated, and at least 12 have been published (Madison and Squier (2)¹; Plum (4)^{3, 14}; Zinberg, Katzenstein, and Wice⁴; Benjamin and Biedermann⁵; Corelli⁶; Bonsdorff⁷; Brøchner-Mortensen⁸; and Palm⁹). These investigations have shown that patients who have recovered from agranulocytosis caused presumably by amidopyrin react to small doses by a sharp fall in the granulocytes, often accompanied by fever, malaise, and dysphagia. It has also been proved that they do not react to substances like sodium diethyl-barbiturate and aspirin (Madison and Squier,¹ Benjamin and Biedermann⁵), and von Bonsdorff⁷ has demonstrated that a patient recovering from agranulocytosis which was caused by arsphenamine (salvarsan) did not react to amidopyrin. Evidently the hypersensitivity is specific, in the sense that convalescents from agranulocytosis with a different ætiology are not hypersensitive to amidopyrin.

* The first part of this communication was read at the Congress for Internal Medicine in Copenhagen, June, 1935.
¹ Madison and Squier¹ have also published experiments which show that cutaneous application of a 40 per cent. amidopyrin emulsion can cause a fall in the leucocytes, in addition to cutaneous lesions in patients hypersensitive to amidopyrin.

A CASE INVESTIGATED

It seems important to record further tests of this kind, and we therefore bring forward the following report:—

The patient, a woman of 25, was treated in the Aalborg County Hospital for chronic rheumatic polyarthritis in 1932, 1933, and again in 1935. During her first stay in hospital, in 1932, she was given amidopyrin for a few days only—a total of 1.8 g. She did not take any amidopyrin in the interval between her first and second visits to hospital. When admitted in 1933 she received 0.3 g. three times daily from Feb. 9th till July 3rd when she was discharged from hospital—in all 126 g. On discharge she continued to take the same dose almost every day until the middle of April, 1934 (total about 250 g.). She then developed pains in the throat, cough, and a rise in temperature to 40° C., but for some reason or other she stopped taking amidopyrin on her own account; she improved rapidly and her temperature was normal in a week. She again took amidopyrin (0.3 g. three times a day) from the middle of May until the beginning of July—in all 40 g. She began to feel very tired and again had a rise of temperature to 40° C., vomiting, and after a few days pains in the throat. At this time she read in a newspaper about the danger of amidopyrin and stopped taking it. This attack lasted 5–6 days. She felt well afterwards apart from her joint pains. In January, 1935, she tried a single dose of 0.3 g. amidopyrin and this was followed by fever, pain in the throat, and malaise, the attack lasting 24 hours.

On April 9th, 1935, she was again admitted to hospital and treated with sodium salicylate (1.0 g. six times daily). We decided to see whether hypersensitivity to amidopyrin could be proved in her case, in order, if possible, to confirm the suspicion that the two or perhaps three attacks she had had at home could be ascribed to agranulocytosis. We first estimated the number of leucocytes when salicylate was given alone. Ten counts were made in the course of 24 hours, and as will be seen from Fig. 1 there were only small variations, which are undoubtedly normal spontaneous fluctuations. Nor did the differential counts show anything particular.

On April 21st a leucocyte count was made at 8 A.M., and then 0.2 g. amidopyrin was given. After this the leucocytes were counted every half-hour until 9 P.M., on the following day every hour from 8 A.M. till 8 P.M., the next day four times, then twice, and on the following three days once each day—in all 49 differential counts. As is shown in Fig. 2 there was an initial fall from 10,000 to 7100 granulocytes in 1–2 hours, then again a short rise followed by a protracted fall to 1900 at 7.30 P.M.—that is, a fall to less than 20 per cent. of the initial value. The lowest granulocyte count was 45 per cent. The curve rose slowly again, but only reached roughly normal values four days after the test dose was given. It will be seen from the curve that the granulocyte decrease lasted the longest. The total number rose more rapidly than the granulocytes on account of a relative lymphocytosis.

While previously there had been less than 1 per cent. granulocytes with single-lobed nuclei, at 4 P.M. and after there were 4–6 per cent. They remained at this height for about five hours and then decreased and varied between 0.3 per cent. and about 2 per cent. On the day following the dose of amidopyrin 6 per cent. myelocytes and

FIG. 1.—Patient subject to agranulocytosis. Effect of sodium salicylate (1.0 g. six times daily) on white cell count.

myeloblasts were found at one count, and two days later 3 per cent. at one count, while only an occasional cell of this kind was observed at the other counts.

Concurrently with these events the sedimentation test showed the following: on April 21st, before the administration of amidopyrin, 11 mm. after one hour; at 4 P.M., 19 mm.; on April 22nd, 13 mm.; on the 23rd, 16 mm.; on the 24th, 14 mm.; and on the 25th, 10 mm.

The patient became ill five hours after the dose with frontal headache, lumbar pains, slight dysphagia, nausea, and vomiting. Next day she complained of lassitude, after which the symptoms ceased. Her temperature rose from 37° to 38.2° C. and later to 38.6°.

This experiment shows very plainly that the patient was hypersensitive to amidopyrin and reacted by a very pronounced fall in the number of leucocytes, mainly granulocytes. There were, at the same time, signs of an increased formation or outflow of granulocytes. On the whole the results of the experiment are in accord with those previously published.

The case is of interest also because the experiment strongly suggests that the two or three attacks the patient had at home were attacks of agranulocytosis caused by amidopyrin. In this respect it resembles the published cases of relapsing agranulocytosis in which the attacks were always caused by taking amidopyrin. Fairly large total quantities were needed in our case to make the patient sensitive. Before the first attack she had received about 380 g.

during some fourteen months, and it was not until then that it seemed to make her ill. Like earlier cases this shows, that because a patient has been given amidopyrin for a long time, it does not follow that he can tolerate it.

THE ENDOCRINE FACTOR

Experiments such as the above seem to prove that amidopyrin can cause agranulocytosis in hypersensitive persons. But which are hyper-

FIG. 2.—The same patient. Effect of a single dose of 0.2 g. amidopyrin taken at point indicated by arrow.

sensitive, and why? Is the condition periodic or constant? And how does this granulocytopenic reaction develop? We have tried to answer these questions, and our results may be of interest though negative.

Of the 7 cases of amidopyrin agranulocytosis in our series² all but one of the patients were middle-aged or rather elderly women, the exception being a woman of 33. The diseases for which they were treated before they developed agranulocytosis were very various—namely, pernicious anæmia (1), polyarthritis (1), Graves's disease (1), adiposity plus arthritis of the shoulder (1), diabetes mellitus (1), adiposalgia and varicose veins (1), and headache and indisposition attributed to menopause (1). Different as these conditions appear at first sight, they have (at any rate five of them) one common feature—namely, that endocrine function can be assumed to be abnormal.

Since endocrine disturbances are supposed to play a part in the production of allergic phenomena it might be supposed that patients with such disorders would be predisposed to amidopyrin hypersensitivity, and we have accordingly studied the leucocyte variations after amidopyrin in 19 patients with various diseases in which endocrine function was presumably abnormal—namely, diabetes mellitus (9), Graves's disease (4), Addison's disease (1), chronic rheumatic polyarthritis (1), primary progressive polyarthritis (2), dystrophia adiposo-genitalis (Fröhlich) (1), and pituitary dwarfism (1). In these patients the total number of leucocytes as well as the granulocytes were counted, a total of ten counts being made in the 24 hours (at 8, 9, 10, and 11 A.M., noon, and 1, 2, 5, and 8 P.M., and again at 8 A.M.). Amidopyrin (0.2 g.) was administered directly after the first count at 8 A.M. In 4 of the patients an equal number of counts were made before the administration of any drug in order to get an idea of the normal daily fluctuations. Similar counts were made in 2 cases after giving 1.0 g. acetosalicylic acid to see if any leucocyte variations occurred in response to that

Holten¹²), but this does not seem to hold good since Palm⁹ has reported a case of amidopyrin agranulocytosis without achylia, and we have not been able to demonstrate any effect of amidopyrin on the leucocyte count in 3 patients with definite achylia. It is accordingly impossible to arrive at any conclusion as to whether a patient is or is not hypersensitive

FIG. 4.—Patient suffering from Graves's disease. Effect of 0.2 g. amidopyrin.

to amidopyrin merely by considering the "basic disease" of the patient.

Figs. 3 and 4 represent the leucocyte and granulocyte variations in two typical cases. The normal fall in leucocytes between 10 A.M. and noon and the normal rise between 2 and 4 P.M. are easily discernible. They represent the normal "tide" which occurs twice every 24 hours, for there is a similar one between 9 P.M. and 3 A.M. independent of muscular activity, consumption of food, sleep, or temperature. These "tides" were first demonstrated by Shaw.¹³

SUMMARY

(1) A case is recorded of amidopyrin hypersensitivity with granulopenic reaction in a woman aged 25, who had had two attacks, at home, of what was supposed to be agranulocytosis. The patient had received about 380 g. of amidopyrin in the course of 14 months, before the symptoms of hypersensitivity appeared. (2) An examination of the agranulocytosis cases in the hospital (all attributable to amidopyrin) showed a high incidence of endocrine disturbances. An attempt was accordingly made to discover whether patients with endocrine disorders show a greater leucocyte response to amidopyrin than other patients or whether they react abnormally at all. It was not possible to demonstrate any such difference.

FIG. 3.—Patient suffering from Graves's disease. Effect of single dose of 0.2 g. amidopyrin.

preparation. Control counts were also made on 6 patients admitted for other diseases (carcinoma of stomach, bronchial asthma, and neurosis), after 0.2 g. amidopyrin. The result of these investigations shows that at any rate with the small doses of amidopyrin used here one cannot demonstrate any difference between the leucocyte variations of patients suffering from endocrine diseases and those of patients suffering from other diseases or from normal fluctuations (Figs. 3 and 4).

It has further been suggested that achylia might predispose to amidopyrin hypersensitivity (Moltke,¹¹

THE TREATMENT OF ACUTE FRONTAL SINUSITIS

By T. B. LAYTON, D.S.O., M.S. Lond., F.R.C.S. Eng.

SURGEON TO THE THROAT AND EAR DEPARTMENT,
GUY'S HOSPITAL, LONDON

THE treatment of acute frontal sinusitis should be purely medical. First let the bowels be emptied. My grandfather used a blue pill and a black draught which he called "a birch broom and a bucket of water." I prefer castor oil because of its certainty of action and because it leaves the patient costive for a while. Once the gut has been emptied it may be left to itself till the invasive stage of the acute infection has passed. It is the small intestine that needs to be emptied, and a full colon or an isolated scybalous mass may prevent this. It is then that a skilled nurse should be called in. She should be able to deal with it within a limit of 48 hours. It is sometimes difficult to persuade those who are in attendance on the patient of the need for the brisk purge when he or she has "taken something" or "always looks after that." The little dose of salts or senna should be neglected and the emptying process started afresh.

The next point is position. The ordinary method of propping a patient in bed is never effective. While he is upright a shortness of the hamstrings may make the position a cause of discomfort or even of pain. To relieve this he bends the hips and knees and shortly sinks down. He then lies upon the lower part of his chest inhibiting movement in this region and thus diminishing the air-entry into the bases of the lungs. If the patient is nursed in bed he needs a pillow under the knees lashed to the head. Better is it to let him be in an armchair. The idea of nursing a patient "in bed in an armchair" is a difficult one to get into the minds of medical men, and still more into those of the nursing profession. Yet it may be remembered that Hajek kept all his patients after the septum or a sinus operation in this position for 48 hours; and that in acute infections Sydenham, who practised before Clifford Allbutt had invented the clinical thermometer and therefore dealt with "fever" rather than with "pyrexia," constantly warns us that "the patient should sit up at least some hours every day, much experience having shown that this is of singular service"¹; or advises him "to keep his room without lying always in bed."² Personally I would not even keep the patient in the armchair but leave him some freedom to move about. He can then use a commode or, if the house be warm, go to the closet and thus be spared the agonies of the bed-pan. However the patient is nursed there is a small point that needs attention. The head must be in a position slightly flexed, but this must not be sufficient to cause the slightest obstruction above the clavicle. It is remarkable how easy it is for some slight pressure to happen on the jugulars, and this results in a great increase of the headache. Further, the head must be so retained by pillows that the patient does not have to use the muscles of the neck to balance it in this position. I would not mention this point did I not see it so often neglected.

The room must be warm but well ventilated, of

an even temperature, and I believe that it is better when the atmosphere is moist. I suspect that we have neglected a valuable remedy in giving up the bronchitis kettle for this complaint.

We come next to diet. The most important factor is the fluid. I demand that my nurses should get 300 ounces into an adult in a severe case. This will not be effected without personality on their part as well as perseverance and a set organisation. I have described elsewhere³ how this may be done. The fluid usually given is fruit juice and water with sugar or glucose added, and the latter then provides a considerable caloric value; but to some it is a sickly drink and efforts should not be made to compel it against the patient's wish. Plain water is better than no fluid. The use of rectal salines should not be necessary in this complaint and are disturbing to the patient, who should be kept at rest except when movement is voluntary. Food should be given as well, and if he will the patient may take anything. It is a good sign. Probably a light farinaceous diet is all that he will feel inclined for with perhaps boiled fish and potatoes. The diet should include some roughage to begin to replace that which has been lost.

That is all the treatment that is necessary. Two other things may be considered, drugs and applications to the nose. I am opposed to any attempt to bring down the temperature artificially by any medication. Again to quote Sydenham: "The fever itself is no other than the instrument of nature, by means whereof she separates the vitiated parts of the blood from the serum."⁴ The use of salicylates prolongs the convalescent period, is lowering to the patient, and likely to result in the inflammation passing on to the suppurative type that needs prolonged treatment possibly of an operative nature after the patient otherwise is well. Pain is the great indication for medication, and a small dose of aspirin may relieve this in a slight case. In the severe type however where pain is acute it is better to be certain of its relief by an injection of morphia, or if it is continuous to keep it under by a mixture given every four to six hours and containing four or five drops of laudanum according to the need.

Locally it is the custom to apply to the mucous membrane of the nose cocaine and adrenaline, or more fashionably to-day ephedrine. I have given these up. I cannot say I have known them to do any harm, but cases do as well without, and I believe they cause the mucous membrane to shrivel but slightly for a short period and to swell the more for the rest of the time intervening before the next application. The only indication for nasal medication is that the patient expects it, and then some mild menthol ointment (0.5 per cent.) placed within the nostril is the best because the least disturbing. So also I have given up washing out the maxillary sinus, it is distressing to the patient. A perfection of anaesthesia cannot be obtained in the inflamed state of the mucous membrane, and I have not found it of value in this acute stage. The removal of the front end of the middle turbinal which I have done in the past I now believe actually to be dangerous. When the patient is in hospital, with the appliance at hand, the use of a light bath to the head seems to be of value if the patient likes it; but if it be objectionable to him it should not be pressed; nor would I have the patient admitted

especially for this. In his own home which combines the elasticity of movement and rest in the upright position that I have discussed above the patient is best if the nursing is possible that is needed in a severe case.

There remains to be discussed the question of inhalations. These are undoubtedly of value once there has occurred a passage through the nose. It is my practice in hospital to alternate the hot-air bath with a menthol inhalation. I have no evidence that this is better than the older Friar's balsam.

We may then sum up the treatment of acute sinusitis, of which the involvement of the fronto-ethmoidal cells is but a part, by saying that there is no room for surgery and that the medical treatment is the minute attention of a hundred details, many of them of the most homely nature, rather than the exhibition of any specific drug or therapy.

UNDESCENDED OVARIES

BY R. MILNES WALKER, M.S. Lond., F.R.C.S. Eng.
SURGEON TO THE ROYAL HOSPITAL, WOLVERHAMPTON

SINCE I recorded two years ago a case of undescended ovary which presented a number of points not previously noted, the same patient has shown further interesting features, while accounts of two other cases in which the anatomical findings were somewhat similar have been brought to my notice and are briefly reproduced for comparison.

The case already reported¹ was that of a girl of 14 who had never menstruated, but who was admitted with pain in the right iliac fossa of 48 hours' duration.

At operation through a gridiron incision the right ovary was found lying in the right iliac fossa behind the caecum, embedded in a mass of recent blood-clot. A fairly well-developed Fallopian tube was present, but owing to the position of the incision the appendages on the opposite side could not be examined; a note at that time that the uterus was thought to be well developed has now been shown to be erroneous. The ovary was removed with the blood-clot surrounding it. She was normally developed as regards the secondary sexual characteristics, but there was no vaginal orifice, though the labia majora and minora were well formed.

As previously reported, she began to complain of pain on the left side some four months after her operation, stating that this was similar in type to the pain she had for two days before her operation, only on the opposite side. This pain lasted intermittently for three months, and then passed off for more than a year. It did, however, recur, and gradually got more intense, so that eventually, four years after her first operation, it was preventing her from doing her work as a polisher. The pain started as an aching in the left iliac fossa, at first with intermissions of no discomfort, but gradually increasing in intensity and becoming continuous; at no time could any history of monthly periodicity be obtained, but the pain was definitely worse after exercise, and eased to some extent by lying down. There was sometimes a little tenderness internal to the left anterior superior iliac spine, but no swelling could be felt at any time. However, the intensity of the pain made her willing to submit to a second operation.

This operation was performed on July 23rd, 1935, through a midline incision. The uterus was found to be considerably smaller than normal, being only about 4 cm. in vertical measurement, forming a short stump rising out of the floor of the pelvis. Attached to its two cornua were bands running laterally, in folds of peritoneum looking like diminutive broad ligaments, to the lateral walls of the pelvis where they led to fimbriated Fallopian tubes each on a short mesentery. Each tube was therefore represented by a well-formed fimbriated extremity and

an adjacent portion of tube, which gradually contracted into a fibrous band running to the undeveloped uterus. This band had been mistaken at the previous operation for a completely formed tube on the right side.

The left ovary was found in the left iliac fossa, attached without a mesentery to the posterior abdominal wall and lying to the outer side of the descending colon which had a short mesentery; it was situated at the level of the iliac crest, its upper pole being 4 cm. below the lower pole of the kidney. It was spindle-shaped, 5 cm. long and 1.5 cm. broad, the long axis being vertical; blood-vessels entered its upper pole, while from its lower extremity a fibrous cord ran down in the retroperitoneal tissues in the direction of the inguinal canal.

In view of the fact that the ovary was almost certainly the cause of her pain, but was her only functioning one from the point of view of its internal secretion, it was decided to denervate the organ, leaving only its blood-supply. The organ was therefore detached from all its surroundings, leaving only the ovarian artery and a few veins entering its upper pole as its sole attachments. All the connective tissue was then carefully dissected off these vessels for a length of 3 cm. during which process what appeared to be a number of nerve-fibres were divided. The ovary was then returned to its bed in the left iliac fossa, and fixed with a few stitches, partly covered by peritoneum to prevent torsion of its pedicle. As it was thought that the undeveloped uterus might also give rise to pain, the presacral sympathetic nerve-fibres were dissected out and divided. The patient made a rapid recovery and has had no recurrence of her pain, being now back at work four months after the operation.

Evans and Cade² recorded a very similar case, but here the failure of descent was unilateral, and the fimbriated extremity of the tube had remained in contact with the ovary; the patient was a girl of 22 years, with pains in the right side of 18 months' duration. At operation the ovary was lying to the outer side and behind the caecum and close to it was the fimbriated extremity of a tube; the remainder of the tube was absent, and the right side of the uterus was undeveloped, it being of the type described as left unicornis. The left ovary, broad ligament, and tube were normal. The undescended ovary was removed and the pain did not recur.

Another case is recorded by Forbes.³ Here both right and left ovaries were arrested at the level of the fourth lumbar vertebra lying to the outer sides of the caecum and descending colon respectively, and alongside each was the fimbriated extremity of a Fallopian tube. The remainder of the tubes was absent and no trace of a uterus could be found. The patient had had an operation to make an artificial vagina three years before. Her symptoms, at the age of 23, were due to hæmorrhage into the peritoneal cavity, from a small follicular cyst of the right ovary, there being abdominal pain of 24 hours' duration. The hæmorrhage was controlled by a suture and the ovary not removed.

The normal descent of the ovary appears to depend upon the proper development of Müllerian ducts; in Evans and Cade's case there is normal Müllerian formation on the left side, whereas it is lacking on the right with consequent absence of the Fallopian tube, except its upper end, which remains in the vicinity of the ovary. Forbes's case represents complete absence of Müllerian ducts, whereas in Pidcock's case,⁴ referred to in my previous communication, these are present but not fully developed, the uterus being abnormally small but yet capable of menstruation. In my own case the Müllerian ducts are undeveloped, but the fimbriated extremities of the tubes, derived from Kobelt's tubules, have descended considerably further than the ovaries.

The cause of the pain is not always obvious. In Forbes's case and in this case on the right side, the

condition presented acute symptoms which were due to hæmorrhage, but in this one on the left side, as in Evans and Cade's case and in Pidcock's, the cause of the pain is obscure, there being no question of torsion, or of pressure on the organ, which was well developed apart from its position. The fact remains, however, that the organ need not be sacrificed when it gives rise to pain, but that this can be relieved by depriving it of its nerve-supply, carefully preserving the blood-vessels, so that it may continue to maintain its functions as an organ of internal secretion.

Once again I wish to express my thanks to Dr. W. Goldie and Dr. G. W. Campbell for their coöperation in following this patient.

Clinical and Laboratory Notes

"IDIOPATHIC" STRIÆ ATROPHICÆ OF PUBERTY

BY F. [PARKES WEBER, M.D. Camb., F.R.C.P. Lond.
SENIOR PHYSICIAN TO THE GERMAN HOSPITAL, LONDON

IN my article on "idiopathic" striæ atrophicæ of puberty in THE LANCET of Oct. 19th, 1935, I described a remarkable example of the condition in a healthy girl, aged 13½ years. The striæ, which owing to their bright red colour must have been of fairly recent origin, were transverse and somewhat irregularly situated over her back from the level of the tenth dorsal vertebra downwards. That her rapid growth in height and general development had

Diagram showing the position of the striæ on the patient's back.

something to do with their onset there could be no doubt. She seemed bodily and mentally developed at least two years beyond her age and had commenced to menstruate at 12 years of age. The presumption was that the striæ would gradually become paler and less conspicuous, and would give rise to no trouble (unless from their appearance).

I have recently seen striæ atrophicæ of very similar distribution in a man, an English park labourer, aged 44 (see Figure). They are limited to the lower (lumbosacral) part of his back and are transversely, somewhat irregularly, distributed, more on the left than on the right side. But they are quite pale, whereas those on the girl's back were red. Obviously they are very old; the patient knew nothing about them and was apparently not even aware of their presence before his recent examination. I can only think that they were connected in some way with rapid growth at puberty. The patient himself came under observation for some totally different complaint, but his history shows that he did indeed develop very rapidly at puberty, for he was permitted to join the army when he was only 15½ years old,

pretending that he was already 18. The two cases (in both of which the Wassermann reaction was negative) do really throw some light on each other and on the development, without any subjective symptoms, of such cases of "idiopathic" striæ atrophicæ of puberty, and also on the prognosis.

Some would prefer to call the condition in both cases "atrophydermia striata (linearis)" by analogy with cases of "atrophydermia (morphœa) guttata," but I believe that the analogy is a false one, though I have heard of a case in which idiopathic cutaneous striæ were combined with idiopathic drop-like atrophy of the skin.

AGRANULOCYTOSIS AFTER TAKING AMIDOPYRIN

BY R. F. L. HEWLETT, M.R.C.S. Eng.

ASSISTANT PATHOLOGIST, ARCHWAY GROUP LABORATORY,
LONDON COUNTY COUNCIL

AMIDOPYRIN (Pyramidon) has been incriminated as often causing, or being a factor in the production of, agranulocytosis. Plum¹ gives a record of 128 cases following the taking of amidopyrin in therapeutic doses. He also describes an experiment in which he gave a single dose of 0.2 g. to a patient who had recovered from an attack of agranulocytosis. He took frequent blood counts and found that the white cells were profoundly modified, both with regard to the total number and the distribution between the granular and non-granular cells, for as long as twelve days. In a similar experiment on two patients, Madison and Squier² produced leucopenia and in one of the cases complete disappearance of the granular cells. Adams³ also considers the drug to be a cause of agranulocytosis.

The present report concerns a patient who had been in the habit of taking tablets containing amidopyrin whenever he felt "a cold coming on," and he had been doing this for several years.

He was a man aged 60, and was admitted to hospital with a history of having been ill for five days. His first symptom was aching pains in the limbs followed by a sore-throat which gradually became worse until he was unable to swallow and had difficulty in speaking. On admission his temperature was 102° F. His throat was seen to be covered on both tonsils and on the uvula with a yellowish membrane and discharge. A swab was taken and a film showed *Oidium albicans* and Gram-positive cocci: on culture a growth of *O. albicans* and non-hæmolytic streptococci was obtained. No Vincent's organisms were seen. A blood count showed the following figures: red cells, 4,980,000 per c.mm.; hæmoglobin, 84 per cent.; colour-index, 0.85; white cells, 600 per c.mm.; lymphocytes, 100 per cent.; red blood corpuscles normal in appearance and platelets in normal number. The condition was at once recognised as one of agranulocytosis. The patient died 6½ hours after admission.

At autopsy the fauces and epiglottis were found to be very œdematous and septic. The subcutaneous tissues of the neck were œdematous but there was no pus. Culture of the œdema fluid yielded a pure growth of pneumococcus group 4. There were a few slightly enlarged glands in the neck. The other organs showed no abnormal appearance. By naked-eye examination the bone-marrow in the femur was fatty and that of the vertebrae grey. Sections of the bone-marrow showed an almost complete absence of granular cells but an increase of lymphocytes.

On making inquiries of the relatives they stated that the deceased had felt a cold coming on and had taken some tablets, and a bottle containing 20 of these was handed over. The bottle originally contained 100 tablets and was bought on Sept. 8th. The patient died on Oct. 19th; thus during a period of about five weeks from Sept. 8th to Oct. 19th, 80 tablets had been taken. The tablets were analysed by Dr. Ryffel who found that each contained

32 per cent. of amidopyrin or about $1\frac{1}{2}$ grains. He also extracted 30 grammes of liver and after evaporation obtained a small quantity of needle-shaped crystals consisting of a basic substance analogous to amidopyrin, from which it may be inferred that this drug had been taken in considerable amount.

I wish to express my thanks to Dr. W. R. M. Turtle, St. Mary Islington Hospital, for allowing me to publish this case, to Dr. J. H. Ryffel, Guy's Hospital, for supplying me with the results of his analysis, and to Mr. Bentley Purchase, H.M. coroner, for the use of his notes.

A CASE OF

ASTHMA SENSITIVITY TO CHROMATES

By W. INGRAM CARD, M.D., M.R.C.P. Lond.

FIRST ASSISTANT TO THE MEDICAL UNIT, ST. THOMAS'S HOSPITAL;
LATE HOUSE PHYSICIAN, BRITISH POSTGRADUATE MEDICAL
SCHOOL AND HAMMERSMITH HOSPITAL

THE toxic effects of chromate compounds were first experimentally produced by Gmelin¹ in 1824. In industry they have been recognised for more than a century,^{2,3} but there is little mention of any respiratory complications in the literature. Delpech and Hilaret⁴ noted the occurrence of what appears to be asthma in four cases. These workers were subjected to a variety of risk and were not of course shown to be specifically sensitive to chromates. Legge⁵ mentions a case. The published records have recently been reviewed by A. R. Smith,⁶ who notes mention of this complication by Wutzdorff and Lehmann. Smith's case was of general chrome poisoning with associated asthma in a man with many previous attacks of asthma and hay-fever. The asthma was not a prominent symptom. Recently, Joules⁷ produced an asthmatic attack in his case by the intradermal injection of potassium dichromate.

The following case of a woman who appeared to be sensitive to chromates may be not without interest.

CASE RECORD

In February, 1935, Mrs. A., aged 28, was admitted to the Hammersmith Hospital complaining of dyspnoea and cough for two months. She came of healthy parents who showed no history of allergic disease. The patient had previously had no asthma, hay-fever, urticaria, or eczema.

History.—For some years previously she had worked in a pickle works and in a sweet-making factory without suffering from any skin complaint. For the eight months before her illness she had worked in a chromium-plating factory as a polisher. Her work consisted of polishing nickel- or chromium-plated articles with either a lime powder or "compo" spread on a revolving brush. The "compo" used was either green or white. The former is chromium oxide in a basis of stearine, while the latter is fused alumina in the same basis. Polishing and plating took place in the same room so that she was in addition exposed to the fumes from the plating tanks. The atmosphere was excessively dusty. No gloves, respirators, or any protective clothing were worn. An exhaust fan adjacent to the polishing brush, according to the patient, was ineffective.

Five months after starting work and three months before admission she noticed a cough which got slowly worse. This was accompanied by increasing dyspnoea and some frothy mucoid sputum. She had no hæmoptysis.

She had been first admitted to the hospital some three weeks earlier, but after a week in bed her symptoms had disappeared and she discharged herself for fear of losing her employment. Two months before admission a rash started on her neck and had since spread to her face and upper eyelids and to the upper part of her chest.

On admission she was slightly dyspnoeic at rest, and examination of her chest showed rhonchi all over both lungs. Both pupils were sluggish to light. The remainder of the physical examination was normal. The urine contained nothing abnormal. Her skin was seborrhœic with some hyperidrosis of the palms and axillæ. There was a chronic eczematous rash over the neck, chest, and arms. In the neck and on the back of the hands there were patches of lichenification. Her nose and throat were examined and were reported normal with no ulceration but some slight crusting. A radiogram of her chest was reported on by Dr. Duncan White: "the appearances in the lungs are those of chronic bronchial catarrh."

Treatment.—The skin condition was treated with calamine lotion and then with Lassar's paste and coal tar. After a fortnight in bed the skin condition had cleared except for some of the more chronic patches. Her dyspnoea had ceased and clinically her condition was normal.

Tests of Sensitivity.—It was then decided to test her skin sensitivity to chromates. For this purpose two solutions were made up: 4 per cent. potassium dichromate and 1 in 1000 acriflavine, which matched the colour, as a control. 0.1 c.cm. of the dichromate solution was injected intradermally into one forearm and 0.1 c.cm. of the control into the other at 8 p.m. At 10.30 p.m. she had a severe attack of asthma which woke her up. She was seen in a typical attack, leaning forward, weeping, and gasping for breath. Her breathing was laboured and there were audible rhonchi. She was rapidly eased by the injection of adrenaline. Twelve hours later she complained of an irritating rash. The rash consisted of small erythematous papules aggregated into patches on the neck, shoulders, chest, and to a slight extent on the back, abdomen, and forearms. It was most marked in the areas previously attacked by the rash. There was some œdema of the eyelids of which she had previously complained. In 36 hours the asthmatic attack had almost disappeared and the rash had improved. Similar injections in a control produced no effect. Beyond some increased erythema, there were no definite local reactions to the injection.

Patch tests using the various finishing powders employed in her work were applied to the leg, "limestone," "green compo," "white compo," and boric acid to act as a control using the technique described by Bray.⁸ There was a slight reaction to "limestone." Dr. Sibyl Horner, of the Home Office, who kindly saw this patient, was of the opinion, on clinical grounds, that the rash was a lime dermatitis. Patch tests on a control were negative. Four days later 0.1 c.cm. of 1 in 1000 acriflavine was injected intradermally into the forearm. There was no effect, though the patient anxiously waited for an asthmatic attack.

It is generally recognised that the chromates are far less active than the dichromates. Her reaction to chromates was tested, two days later, by the intradermal injection of 0.1 c.cm. of 4 per cent. potassium chromate. Five hours after the injection the patient woke up in a severe asthmatic attack which was eased by the administration of adrenaline. Sputum taken during this attack showed numerous eosinophils. Rhonchi were still present in the chest 36 hours after the attack.

Experimentally chromates can be absorbed from the stomach though symptoms of general intoxication in chromium-workers are very rare save after massive exposure. An attempt was therefore made to provoke an attack by the administration of potassium dichromate given orally. The doses used were $\frac{1}{5}$, $\frac{2}{5}$, and $\frac{3}{5}$ grain, given on successive days in her food. No effect at all was observed. She was further tested for sensitisation to general proteins by scarification in the usual way. All gave negative results except for a slight reaction to "fungi." In the summer she suffers from epidermophytosis. She was discharged free from symptoms and advised not to seek re-employment as a worker in this

factory. Despite this advice she returned to the same work. Her symptoms immediately recurred. She has since obtained other employment and has been entirely free from asthma for six months.

SUMMARY

(1) A patient, with no previous allergic history suffered from asthma after five months' exposure to the fumes and dust of a chromium-plating factory. (2) The asthma rapidly cleared up after a week in hospital. (3) The symptoms recurred on returning to work but disappeared on readmission to hospital. (4) An attack was provoked by the injection of 0.004 g. of potassium dichromate. A further attack was provoked by the injection of 0.004 g. of potassium chromate. (5) Except for a slight attack requiring no treatment, no asthmatic symptoms occurred in hospital other than those produced artificially.

(6) No reaction to oral administration was noted. No skin reaction to the ordinary protein groups was obtained. (7) Since she obtained other employment there have been no further attacks. (8) The course of the disease suggests that the patient was asthma-sensitive to chromates.

I am grateful to the medical officer of the London County Council, and to Prof. F. R. Fraser for permission to publish this case.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF LARYNGOLOGY

At a meeting of this section, held on Dec. 6th, with Mr. LIONEL COLLEDGE, the president, in the chair, a discussion took place on

Acute Frontal Sinusitis

Mr. F. HOLT DIGGLE (Manchester) began by speaking of the seriousness of this condition with its risk of septicæmia, osteomyelitis, or intracranial extension. Such complications might follow conservative treatment, if unduly prolonged, or might result from precipitate surgery. He was sure the virulence of this type of infection had increased in the last few years. Clinically the condition became manifest by pain and tenderness over the anterior wall and/or floor of the frontal sinus, with or without œdema of the overlying soft parts or orbital tissues; the duration was a few days or a few weeks, and there might be a homolateral maxillary sinus infection. In diagnosis radiography was usually of great assistance, though occasionally misleading, but he placed no reliance on transillumination of the frontal sinus. For purposes of discussion the cases could be classed as pyrexial and apyrexial; he preferred this distinction to catarrhal and suppurative. The two commonest types of infection met with were those due to *Streptococcus pyogenes* and *Staphylococcus aureus*, and there should always be a bacteriological examination, so that, if required, the right kind of serum might be used. In carrying out conservative treatment he kept the patient semirecumbent and applied heat externally; warm mentholated vapours were inhaled, and astringents such as ephedrine and adrenaline, or a 5 per cent. solution of cocaine hydrochloride and adrenaline (1 in 1000) in equal parts were applied to the ethmoidal region either with the spray or a cotton-tipped probe. Forty per cent. of his cases had recovered completely under this treatment, but they were all subacute. In this apyrexial group, if the frontal headache and the tenderness were gradually subsiding under conservative treatment, surgical drainage was not needed. It was called for, however, if symptoms increased. In severe cases with fever hasty surgical treatment could be disastrous. The blood infection or toxæmia should be countered by appropriate antiserum at an early stage, especially as the sinusitis might prove to be only a local manifestation of septicæmia. Surgical

drainage was called for, he thought, if there was a pulsating headache, with increasing tenderness, and the condition was not responding to serum therapy and general conservative measures.

In apyrexial types, when conservative measures had failed, Mr. Diggle straightened a grossly deflected nasal septum, and removed a hypertrophied or cystic middle turbinate; the anterior ethmoidal cells were removed so that he could gently catheterise the frontal sinus, but he never used a frontal raspatory. If there was an actual external abscess, or if œdema and tenderness did not subside a day or two after intranasal drainage, he would resort to external drainage. In the toxic pyrexial group he would not adopt any form of intranasal drainage nor resect the nasal septum, nor remove part of a middle turbinate. If conservative treatment failed, he preferred external drainage, making the usual curved incision below the eyebrow, and passing on to the nasal bone. After elevating the soft parts so as to expose the inner part of the frontal sinus floor, he opened the sinus through its floor just above the nasal ostium. This opened any external abscess. He never syringed or mopped out the sinus contents. Before inserting a drain, which best took the form of rubber dam tissue, he smeared the bony edges with pure carbolic acid; this seemed to lessen the risk of osteomyelitis. After lightly smearing the soft parts with thin bipp the outer edges of the wound were brought together with stitches, and the rubber drain was anchored to the lower nasal end of the incision, being removed at the 10th-14th day, by which time the discharge was usually mucoid. Those who believed that a suppurative frontal sinusitis was always associated with suppuration in the ethmoidal cells would probably doubt the wisdom of a simple external frontal drainage without removal of the ethmoidal cells; but did such association always exist? Inspection of those cells, in acute cases, was of no help, and a skiagram might not assist. But if the patient had œdema of both upper and lower eyelids, with possibly some proptosis or ocular displacement—signs of severe ethmoidal involvement—there was no alternative to surgical removal of the ethmoidal cells. The prognosis in such cases was very grave. The coexistence of homolateral maxillary sinus infection did not materially alter the frontal sinusitis measures, except that the ethmoidal œdema hindered frontal drainage. The antrum should always be aspirated, if only to relieve the ethmoidal œdema and promote frontal drainage.

Mr. T. E. CAWTHORNE thought there was an increasing tendency towards conservative measures, because a large majority of the acute cases cleared up under such treatment, and because extensive surgical procedures on the frontal and ethmoid sinuses, at a time before barriers had been established against infection, might start a spreading osteomyelitis, meningitis, or even cavernous sinus thrombosis. The definition of "conservative treatment" depended a good deal on individual taste and temperament; some would consider puncture and lavage of an antrum full of pus in the acute stage as on the rash side, while others thought that a limited opening of the floor of the frontal sinus in acute suppuration was the essence of caution.

Sinus trouble usually followed a cold or was a result of bathing while suffering from nasal infection. He did not know whether it was the maxillary antrum or the anterior ethmoids that were mainly responsible for the spread of infection to the frontal sinus, but suppuration in the ethmoids or antrum was almost always an accompaniment, and it was towards the antrum that one's efforts should be directed. The amount of drainage afforded to the infected frontal sinus would depend on the degree of obstruction of the frontonasal duct. If that obstruction was complete, the pus in the sinus might cause a periostitis, usually in the thin floor, and this would produce some external swelling. Failing relief the pus might spread from the frontal sinus to the neighbouring regions, and, left to itself, would usually follow the line of least resistance and burst through the thin floor to invade the orbit. This was the least dangerous route for it to take. If sufficient drainage could be secured to prevent the retention of pus in the frontal sinus under pressure, any external swelling would subside. Some surgeons believed that complications developing after operations done during the acute stage did so despite the operation; but it was significant that they nearly always appeared, or were discovered, a few days after operation. He had not, so far, seen one of the serious complications develop because an external operation had not been performed. Unless pus had evidently escaped from the frontal sinus into the surrounding tissues, conservative measures should be given a thorough trial before any form of external operation was even considered. Such measures should include steam inhalations, antrum puncture, and lavage (if necessary daily). Removal of any pus from the antrum was of the greatest importance, and he punctured the antrum as a routine, seldom finding it free from infection. In young patients and those unable to tolerate repeated antrum puncture it was permissible to make a limited opening into the antrum through the inferior meatus, large enough to admit a cannula; also shrinking solutions should be applied to the middle meatus and the turbinal. Probably 10 per cent. Protargol was the safest solution, and though sometimes it was necessary to precede its use by a pack moistened with a 10 per cent. solution of cocaine, this should be avoided when possible because of the after-dilatation it produced. Hot fomentations externally, electrically heated pads, or a light-bath might prove of value. Sometimes a catheter could be passed into the frontal sinus, and the pus could be removed by either lavage or suction. Sometimes normal drainage could be assisted by inward displacement or infraction of the middle turbinal. He did not usually favour removal of the anterior end of the middle turbinal, largely because of the reactionary swelling of the mucous membrane around the frontonasal duct. If after ten days the

condition remained stationary, or if there was reason to suppose that pus had spread beyond the frontal sinus, some kind of external operation would be needed, its extent being determined by the extent of the disease. Unless, however, the disease had attacked the diploë of the frontal bone or the meninges, operation should be restricted to a small opening in the floor of the frontal sinus. After the acute symptoms had subsided it was usually necessary to enlarge the frontonasal duct and exenterate any diseased ethmoidal cells encountered.

Mr. WALTER HOWARTH said he did not quite follow Mr. Diggle's separation of cases into pyrexial and apyrexial; very many of the cases showed some pyrexia, its amount depending on the virulence of the infection and the degree of blockage of the frontonasal duct. He was in close sympathy with Mr. Cawthorne's advocacy of conservatism, and he thought Mr. Diggle's figure of 40 per cent. cures by this treatment was low; his own estimate would be double that figure. He also thought that if surgery were withheld longer than was now customary, an even larger proportion would be cured without it. In his clinic very few of the large number of frontal sinus cases seen were operated upon. He did not even believe in the removal of the anterior end of the middle turbinate, though in cases where blockage was complete an attempt should be made to enter the frontonasal duct. He thought it probable that the patients who developed frontal sinusitis had some anatomical abnormality or curious configuration of the duct. Even cases showing much oedema of eyelids often settled down without operation.

Mr. C. A. SCOTT RIDOUT (Portsmouth) emphasised his belief in conservative methods by narrating a case in which the anterior part of the middle turbinal was removed and the patient died from meningitis. He had more faith than Mr. Cawthorne in packs soaked with cocaine; it was seldom that packing and repacking the nose with 10 per cent. solution of cocaine did not produce relief. But there were cases in which one dared not try to get into the sinus because of the obstruction of the septum; the patient was in great pain, and an external incision had to be made to let out pus which was under pressure. He agreed that the radiographic indications were often uncertain.

Mr. HAROLD KISCH welcomed the wave of conservatism and said that at the Central London Ear and Throat Hospital almost none of the frontal sinus cases were operated on. Lavage of the antrum was always carried out, and he regarded it as very important. Though most of the cases were not operated on until the acute condition had settled down, the mortality was not at all high. In one case of osteomyelitis of the frontal bone complicating frontal sinusitis, intensive X rays had stopped the osteomyelitis from spreading, and later, when the sinus was opened, all suppuration had ceased. He thought that small doses of intensive X rays might well be used in some cases.

Mr. T. B. LAYTON said his conservatism went even further than that of the other speakers, for he now neither washed out the antrum nor removed the front end of the middle turbinate. If acute frontal sinusitis was left alone he doubted whether it ever led to septicæmia, osteomyelitis, or meningitis. Anatomically there was no such thing as a frontal sinusitis; the frontal sinus was merely one of a group of anterior ethmoidal cells, all of which grew up towards the angle where the bones of the cranial and nasal cavity met.

Mr. E. MUSGRAVE WOODMAN (Birmingham) disagreed with Mr. Layton, and related a case in which acute head pains, photophobia, and joint involvement were the leading symptoms, and streptococci were grown from the blood; this was clearly a case of acute frontal sinusitis. He held that 90-95 per cent. of cases would clear up on local treatment only.

Mr. LESLIE POWELL (Reading) said that during twenty years he had not operated on a case of acute frontal sinusitis; but recently he had two cases in three weeks of a type not previously encountered—i.e., with a large abscess high up in the centre of the forehead, both frontal sinuses being affected. There had been no cold, and no pus was coming from the nose. He removed all the soft bone he could find, but did not touch the posterior wall. In the first of the two cases he had to explore further, as there was paralysis of the arm and leg on the right side. Pus was coming away from between the meninges and the cortex. The patient died, and a band of thick pus was found passing round the cerebral hemisphere to the occiput.

Dr. W. A. TROUP said that for acute cases he believed in radiotherapy, which was not used in this country nearly as much as in America and on the continent.

Mr. H. G. DOWNER (Hove) spoke as a sufferer from acute frontal sinusitis. His relief came not so much from the use of inhalations as from the employment of the steam tent. Submucous resection had saved the onset of further trouble.

Mr. E. D. D. DAVIS said that in his clinic conservative treatment was adopted wherever possible, but there were cases which operation certainly helped. Sometimes one's hand was forced, especially where the patient had had a previous attack—a thing which always made the speaker anxious. When there was a bulging swelling, and no sleep could be procured, he did not see why a limited middle turbinectomy should not be performed, in order to reach the frontonasal duct. And an orbital abscess could not be left with safety; drainage was needed.

Mr. V. E. NEGUS said he had always washed out the antrum in these cases, which cleared the natural ostium. Some certainly required an external incision.

Mr. J. B. HORGAN (Cork) said he was able to produce a very prolonged astringent effect by using 1 grain of ephedrine with grs. $17\frac{1}{2}$ of cocaine in an ounce of olive oil, with the head in a prone position.

SECTIONS OF THERAPEUTICS AND MEDICINE

At a joint meeting of these two sections held on Dec. 10th, the chair was taken by Dr. DOROTHY HARE, president of the section of therapeutics and pharmacology, and a discussion on

Agranulocytosis

was opened by Prof. L. J. WITTS. The subject, he said, was ripe for discussion in this country. In reports published in the current issues of *The Lancet* and *British Medical Journal* it was stated that sepsis could by itself gravely reduce the number of white cells; that in agranulocytosis these were entirely absent; that 2 or 3 grains of Pyramidon (amidopyrin) could not produce the condition; and that there was always an exudate on the tonsils and red urine. All those statements were, he thought, open to question. He reported seven cases; five of the patients had taken pyramidon and one salol. The illness of the first (a doctor's wife) had been chronic and recovery had followed treatment. The second patient (a surgeon) having taken salol for colitis had complained of exhaustion and had shown 1600 white

cells and 912 granulocytes; he too recovered. The third patient was also a doctor's wife. She had developed an apical abscess after overwork and had taken Veramon and Allonal and been seriously ill with ulceration of the fauces and massive Ludwig's angina, with only 100 granulocytes. She had recovered. The fourth patient had suffered from rheumatoid arthritis and no inquiry about drugs had been made; the leucopenia had been discovered by chance. All these patients had been treated with nucleotide. The condition seemed to affect doctors' families—probably because they took the samples of new drugs. The fifth patient had taken Yeast-Vite, then containing pyramidon, for depression after the loss of her child. She had become worse and developed a septic socket after extraction, a quinsy, and an ulcerated throat. Under symptomatic treatment for the throat she had begun to recover, and then the leucopenia had been discovered. Pentnucleotide had had no effect on her white cells, but these had risen after—probably not because of—injections of Campolon. The sixth patient had taken yeast-vite for pyelitis. Her count had been 1200 white cells. No specific treatment had been given and she had shown spontaneous remission with great outpouring of white cells. She had been unable to tolerate pentnucleotide (tried later), and had been given large doses of liver without benefit. The leucopenia had lasted some time. Complete recovery took months. The seventh patient had come for investigation after hæmoptysis, but leucopenia alone had been found (300 polymorphonuclear leucocytes). She had taken Cachets Faivre for migraine every three weeks for about four years. She had seemed quite fit. Pentnucleotide had made her ill: fever of 102° F., collapse, and aphasia. She had remained stuporose until her death. She had been given massive doses of campolon but had developed an ulcerated throat and complete agranulocytosis. At autopsy there had been a thick greenish exudate over tonsils, pharynx, and œsophagus, and focal lymphocytic infiltration of the bone-marrow, in which no granulocytes could be found. The pathological changes suggested arrest in maturation of the myeloblasts comparable with the megaloblastic degeneration of pernicious anaemia. In animals pyramidon caused changes in the marrow though not complete agranulocytosis; the subjects could not produce leucocytosis when stimulated. Direct incrimination of pyramidon had now been secured by giving test doses, which produced leucopenia, malaise, and sore-throat. Other drugs also caused the disease, and pyramidon could be taken by some people without ill-effects. Nevertheless, pyramidon was the chief cause of agranulocytosis. Liver extract, X rays, transfusion, leucocytic stimulants, and pentnucleotide had been used in treatment, but all appeared to be ineffective. There was some basis for X ray and nucleotide therapy, but in practice the results were disappointing. One reason for the failure of pentnucleotide was insufficient dosage and another was the appearance of troublesome reactions. The time had come for pyramidon to be regarded as a dangerous drug and treated accordingly.

Sir WILLIAM WILLCOX said that the leucopenia seemed to be due to defect of the bone-marrow. No definite cause might be ascertainable, or some probable cause might be found. It was commonest in females from 40 to 50, but no age was exempt. Nutritional features might play a more important part than was at present recognised. The enteric group of bacteria were associated with diminution

of granular leucocytes; in the days when typhoid was much more severe, a membrane might be found in the throat and extending down œsophagus and trachea. Other bacterial invasions might also cause agranulocytosis, notably chronic dental infections. Other conditions sometimes associated with diminution of the granular leucocytes were tuberculosis, virus diseases, and protozoal infections. Various drugs had been accused. Pyramidon had been very largely used. Sir William had frequently prescribed it and had never seen agranulocytosis associated with it. There must be an allergy in connexion with it. To say that the majority of cases were due to pyramidon was going rather too far. Barbiturates seemed to have a deadly effect on the white cells. Many toxic drugs could "knock out" the bone-marrow. Physical causes included exposure to X rays, radium, and mesothorium, anaphylaxis and shock, and achylia. In considering ætiology it was important to distinguish between post hoc and propter hoc; there was an enormous amount of drugging going on to-day. A careful consideration of all the factors possibly concerned was evidently necessary.

Sir William described three cases. In the first, a careful dental extraction had been followed by illness, a membrane requiring tracheotomy, and a fatal agranulocytosis. The second had been suffering from boils for a year; he had developed acute illness and then, after half a dozen cachets containing amidopyrin, he had shown complete agranulocytosis. He had recovered. The third case had been one of toxic fibrositis with parotid abscess and acute fatal staphylococcal septicæmia. For operation on the gland she had had Evipan, and she had about a grain of pyramidon three weeks before death.

Dr. E. C. WARNER said that the failure might be at one of three stages: failure to produce myeloblasts; failure to transform them into myelocytes; or failure to transform myelocytes into granulocytes. The first was invariably, and the second often, fatal. Sternal biopsy was the only way of determining which was present during life. In chronic and relapsing cases the third process was probably present; in many of these there was no history of drugs. In one reported case the agranulocytosis had been shown repeatedly to precede the symptoms. Apart from the oral conditions, the most characteristic feature was weakness, exhaustion, and fatigue. Any relapse might prove fatal, but the prognosis of the chronic and relapsing case was much better than in acute fulminating cases. Exhaustion must be treated, and exposure to any infection must be scrupulously avoided, as must also operation of any kind. The mouth must be treated, and pentnucleotide could be given. Minot had recommended vitamin B. A patient recently seen by Dr. Warner—also a doctor's wife—had previously been suspected of having tuberculosis. She had had a long period of worry and suffered from low backache, colic, poor appetite, diarrhœa, vomiting and migraine at times, loss of weight, and fits of depression. She had had aspirin, veramon, alonal, and phenacetin and caffeine. Later she had shown fever and inflammation around two teeth, without pus. A blood count had revealed 1700 white cells and no granulocytes. After nine weeks' treatment with pentnucleotide, to which she showed good reaction, she recovered completely. Within 18 hours of beginning treatment there had been a marked rise in the white cell count, and a still more striking response was obtained when the dose of pentnucleotide was doubled.

Dr. J. D. ROLLESTON said he had taken a great interest in the disease since its description in 1924, but had had very few cases sent to his fever hospital. Before diphtheria had been differentiated in the nineteenth century, many forms of "gangrenous angina" had probably been diphtheria. Pyramidon had been recommended almost as a specific for measles.

Sir KENNETH GOADBY thought that the exciting cause was not yet very clear, and might be one of many things. He recalled the time when pernicious anæmia had always been ascribed to oral sepsis. Probably agranulocytosis was due to a specific factor. Leucopenia should be looked at very much as the temperature chart was. In a case he had recently published there had been six very severe attacks, each following languor and drowsiness associated with leucopenia and reduced granulocyte count. Mouth symptoms had been late in appearing and the sloughing had been quite different from that of Vincent's angina: a hard leathery slough penetrating deeply into the tissues and without a clear red edge. Two other varieties of nucleotide had been tried, without any benefit, but pentnucleotide had at once caused improvement. The patient, a large florid woman, had lost no weight and had recovered. Only in the later attacks had she developed meningeal symptoms. There had been no history of drugs, but there had been a syndrome highly suggestive of paratyphoid, and on each occasion she had had enlargement of the spleen.

Dr. HERBERT BROWN referred to an analysis of fourteen recorded cases. Only three had recovered; and only three had been attributable to amidopyrin. In the majority there had been a history of sepsis and diagnosis had only been made at a late stage. Sepsis was generally nasal, oral, or pharyngeal. Experimental work had shown that prolonged absorption of toxins in rabbits had little effect, except that of *Streptococcus viridans* which had caused rapid fatal acute granulocytopenia.

Dr. S. W. PATTERSON said that 472 cases had been studied by one observer with a view to investigating the disrupted masses called by American workers "smudges." He showed an analysis of the results. The percentage of cells disrupted varied from 9 to 33, the highest figures being found in splenomedullary leukemia, fibrositis, and a patient who had taken yeast for years. One fibrositic patient had had 3900 white cells, 20.8 per cent. disrupted. After severe exercise his count had dropped below 2000, with 26 per cent. disrupted. Behind the other ætiological factors suggested there might be some hypoplasia of the myeloid structures producing fragility of the cells.

Dr. C. W. J. BRASHER thought that potassium chlorate was useless as an oxidising agent without a strong acid and the potassium might produce anæmia.

Dr. G. L. KONSTAM spoke of an obese female patient recently sent to a fever hospital as a case of diphtheria. She had no granulocytes and a white cell count of 1000. These cases might be found more often in fever hospitals if sought as a routine. She had had dyspnœa and was obviously going to die. Another fatal case had had a hæmorrhagic discharge from his rectum.

NEW WING AT SCUNTHORPE WAR MEMORIAL HOSPITAL.—The new Jubilee block, which was lately opened at this hospital, contains five new wards and cost £15,000. Work will soon be started on a new and larger out-patients' department to meet the growing needs of the district.

REVIEWS AND NOTICES OF BOOKS

Mentality and the Criminal Law

By O. C. M. DAVIS, M.D., D.Sc., Head of the Department of Forensic Medicine in the University of Bristol; and F. A. WILSHIRE, of the Middle Temple, Barrister-at-Law. Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall Ltd. 1935. Pp. 168. 5s.

A DOCTOR would naturally expect that any symptom of insanity would be allowed to justify exemption from criminal responsibility. The legal view is that a man may exhibit many symptoms of insanity and yet may not come within the requirements of such exemption. Here is a broad distinction between the medical and the legal aspects which is well brought out in the book before us, a handy summary written by collaborators who combine the qualifications of both professions. The little book is intended for students and practitioners of law who have no time to dig deeper. There are chapters *inter alia* on drunkenness and irresistible impulse, there is an adequate statement of the terms and the significance of the Rules in *McNaghten's* case, and there is sound advice on advocacy in defences where questions of mental instability arise. In this latter connexion the writers refer to the not infrequent dilemma of the advocate who has to decide between attempting to obtain a verdict of "guilty but insane" or relying on the plea of absence of capacity to form intent. Another problem is occasioned by the inclination of juries to return a verdict of insanity rather than one which involves the death sentence. A judge may set himself to counteract this supposed tendency. Is it better, asked Lord Hewart of the jury in *R. v. Anderson* at Sussex Assizes last March, that a guilty man, if he be guilty, should be punished, or that a sane man, on a false allegation of insanity, should be detained for a long time in a criminal lunatic asylum?

The style of the book is uneven, as may easily happen where two authors collaborate; but the diligent reader will be equipped for forensic emergencies and may be stimulated to pursue his studies elsewhere at his leisure. As law students may grow into judges or legislators, a volume of this kind, which sketches criminal responsibility both from the legal and the medical standpoint, may hasten the day when the views of the two professions of law and medicine will more nearly coincide.

Manson's Tropical Diseases

A Manual of the Diseases of Warm Climates. Tenth edition. Edited by PHILIP H. MANSON-BAHR, D.S.O., M.D., F.R.C.P. London: Cassell and Co., Ltd. 1935. Pp. 1003. 31s. 6d.

SIX years ago when the ninth edition of this manual appeared we remarked that it was indispensable for any who wished to acquire or retain an adequate knowledge of disease in all parts of the British Commonwealth and that tropical medicine is under no little debt to the author for the unremitting industry and vigilance which its compilation has entailed. The tenth edition increases the reader's indebtedness, for the book has been expanded on the clinical side while the classification of tropical diseases has been put on a more natural and ætiological basis. This has meant cutting out much of the medical zoology which can be read elsewhere; Dr. Manson-Bahr indeed expresses his relief that

it is no longer necessary for him to poach on ground that has been efficiently treated elsewhere. In this volume he acknowledges the help of Dr. C. M. Wenyon, Prof. R. T. Leiper, Dr. Marshall Findlay, Major E. E. Austen, Prof. M. A. C. Hinton, and Dr. Russell Amies in various branches; on the pharmaceutical side the text has been revised by Mr. Bernard Smith. The result is a volume only some 8 per cent. larger than its predecessor and still within the reasonable bounds of a handy and practical text-book.

Brain Preparations

By Means of Defibrillation or Blunt Dissection. A Guide to the Macroscopic Study of the Brain. By Dr. J. WILH. HULTKRANTZ, Professor of Anatomy, University of Uppsala, Sweden. Translated from the first German edition by HERBERT J. WILKINSON, Professor of Anatomy, University of Adelaide, Australia. London: William Heinemann (Medical Books) Ltd. 1935. Pp. 48. 10s. 6d.

THE method of blunt dissection or defibrillation as applied to the study of the brain has long been practised at the Anatomical Institute, Uppsala, in the teaching of students. Prof. Hultkrantz has here briefly described the procedure with the help of a series of excellent photographs of dissections obtained. Prof. Wilkinson, the translator, was sufficiently impressed by what he saw on a visit to Uppsala to introduce the method in his own department of anatomy. Only the more careful and patient student who has a preliminary knowledge of the topography of the brain will get much out of this technique, but to those who possess these qualifications it offers a far better means of demonstrating structure than any series of sections can afford. It might be used effectively for museum preparations as well as in the dissecting-room.

Sex

By KENNETH WALKER, M.A., F.R.C.S. London: John Lane, The Bodley Head. 1935. Pp. 130. 3s. 6d.

THIS small book, written primarily for a lay public, contains an unusual mixture of scientific and mystical thought. Mr. Walker is particularly concerned with sex and its environment in the twentieth century. Two of his main sources of information and inspiration are Havelock Ellis and P. D. Ouspinsky, and his theme would appear to be that man's troubles are the result of what man is and his one hope of setting right a disordered world lies in an attempt to change not only his circumstances but himself.

First he discusses very briefly the biological and psychological aspects of sex. He goes on to survey the place of sex in occult and religious systems and points out how far removed are the modern views of sex from those originally held in these systems. For example, the early Christians accepted asceticism with its sublimation of sex as a means to an end, whereas their successors are often disposed to regard the giving up of sex as an end in itself. In discussing abnormalities he prefers to use the word "deviation" rather than "perversion," since the latter word tends to imply guilt. While upholding the institution of marriage and the family as the fundamental unit of society, Mr. Walker has much to say against our present laws and social customs with regard to sex

and marriage, and insists that readjustments must come. In the section on contraception he seems to infer that in England instruction in birth control can only be given surreptitiously even to patients needing it on medical grounds. This state of affairs has been changed as far as the public health services are concerned since the issue of the Ministry of Health's permissive memorandum some five years ago, and voluntary clinics where advice on birth control can be openly obtained have been in existence for as long as fifteen years. Mr. Walker's tolerant views on sex before marriage, and on the satisfaction of the sexual and maternal needs of those members of the community for whom marriage is impossible are worth consideration, especially from those who regard the standards of the younger generation difficult to understand.

Modern Treatment of Burns and Scalds

By PHILIP H. MITCHNER, M.D., M.S. Lond., F.R.C.S. Eng., Hon. Surgeon to H.M. The King; Surgeon and Lecturer in Surgery, St. Thomas's Hospital. London: Baillière, Tindall and Cox. 1935. Pp. 64. 5s.

THIS little book is an amplification of a Hunterian lecture delivered in 1933, and in it Mr. Mitchner sets forth in the clearest terms how burns of all varieties should be treated. A sharp distinction is drawn between burns and scalds, since the prognosis of the former is so much more grave; practical hints are given on the management of burns resulting from special agents such as electricity, tar, cordite, petrol, phosgene, and mustard gas. The author brings forward statistical evidence to show how the mortality-rate from burns and scalds may be reduced to a tenth or less by abandoning methods of treatment which have nothing but tradition to support them, and adopting in every detail the correct application of a 2 per cent. solution of tannic acid in water. The virtues of this solution are explained on theoretical grounds, but it is pointed out that unless the burnt area is properly attended to before and after the application of tannic acid the best results cannot be attained. No practitioner can fail to obtain help from the practical advice which this book provides. So simply is it written and so clearly illustrated that it may also guide those responsible for the organisation of first aid in industrial establishments.

Heredity and Evolution

By A. E. WATKINS, M.A., University Lecturer in Genetics and Cytology, Cambridge. London: John Murray. 1935. Pp. 243. 7s. 6d.

It would be an interesting exercise for the student of biology to read the "Origin of Species" and then Mr. Watkins's book (which might as well have been called by the same title) and to make a précis of the differences and similarities. The main difference in general outlook is that Darwin came at his subject as an observant naturalist while Mr. Watkins is an analytical experimentalist; the main similarity is that both are concerned to discover the mechanism of an evolution which has resulted in the great bulk of the live world being cut up into obvious groups which we call species. Mr. Watkins gives a clear account of the coöperation between experimental breeding and cytology which has been so fruitful these last 30 years, and, recognising difficulties and uncertainties, he evidently inclines to the view that the discontinuous variation studied by Mendel is at the bottom of what Darwin thought came more

gradually. As he points out, changes in genes and especially in their grouping and frequency are known to provide a degree of variability which seems adequate for the play of natural selection and for the production of discrete species. He makes no attempt to discuss the cause as apart from the mechanism of evolution; perhaps, like other modern biologists, he does not distinguish between them and holds that results are determined by means. Hence he rejects Lamarckism in a sentence and makes no mention of the predestination to which the work of such men as Osborn and Broom brought them. His field therefore is rather limited but within it his book should be of use. It has the great advantage of being tempered to the layman's understanding.

An Introduction to Human Anatomy

By CLYDE MARSHALL, M.D., Department of Anatomy, School of Medicine, Yale University. London: W. B. Saunders Co., Ltd. 1935. Pp. 385. 10s. 6d.

THIS small volume is one of the most pleasing books on elementary anatomy that we have seen for some time. Dr. Marshall has set out to interest the junior student, entering a bewildering field of vast extent, and to supply him with connected ideas admitting of expansion as his information grows and deepens. It seems to us that he has done this very well. The order of presentation of his subjects is a commendable variation of that usually employed, and his descriptive work is excellent. The illustrations are of a high order, as may be imagined when it is stated that the muscles are largely illustrated by the exquisite drawings in Braus's "Anatomie"; they lack, of course, the delicate colouring of the originals, but the beauty of the fine line work is well reproduced. Dr. Marshall is to be congratulated on the appearance of so useful and accurate a work.

Tonsils and Naso-pharyngeal Sepsis

By E. A. PETERS, M.D. Cantab., F.R.C.S. Eng., Consulting Surgeon, Royal Ear Hospital (University College Hospital). London: Baillière, Tindall and Cox. 1935. Pp. 92. 5s.

IN this little book Mr. Peters has set himself the task of giving an account of the septic infections of the throat, especially of the tonsils, and of their relationship to the general diseases which may result from so-called focal infection. He describes also the method of removal of tonsils and adenoids, and the palliative treatment of septic tonsils by the suction-cup. He believes a reasonable view of the function of the tonsil to be that it is a "mass of lymphoid tissue of varying size perforated by crypts of variable sepsis; it is protected from physical scavenging by reason of its position, and otherwise not differing from the submucous layers of lymphoid tissue which protect both alimentary and respiratory tracts." We may doubtless attribute certain inaccuracies in this book to the extreme compression necessary to keep down its bulk to 92 pages. Thus, glandular fever with mononucleosis is described as a complication of the operation for removal of tonsils and adenoids, and secondary hæmorrhage occurring from the second to the fourteenth day after operation is stated to happen only in neglected cases. The book, in fact, suffers somewhat from this compression, and is too short to furnish an entirely satisfactory account of the details of this complex subject.

THE LANCET

LONDON: SATURDAY, DECEMBER 14, 1935

THE UNDESCENDED TESTICLE

THE descent of the testis arouses various speculations. Why did Nature change the position of this organ? By what process of natural selection or other evolutionary influence was its transportation successfully achieved; by what intermediate stages, and under what motive forces? Some advantage must be assumed, not only in the descent of the testes but also in their descent at different age-periods in different species. In man they normally reach the scrotum before birth and remain there; in some monkeys they are in the scrotum at birth, but shortly afterwards return to the inguinal canals and remain until puberty when they again descend. In the mouse descent does not come about until puberty, and in the stag the testis occupies the scrotum only during the season of rut. To wonder why these things happen is not an idle pastime, since knowledge necessary for their explanation would be of benefit to mankind; and the only way to get this knowledge is observation and controlled experiment on animals. Through the fundamental work of ASCHHEIM and ZONDEK, and the developments that have followed, the nature of the necessary experiments has now become clear, and we hope they will soon be set on foot. Meanwhile we are faced with the treatment of incomplete descent of the testis in man, and the question how it may best be attempted in the light of current opinion. The reasons why treatment of some sort is required are manifold. As a rule the undescended gland lies within the inguinal canal or close to its internal or external ends, where it is not freely mobile and is exposed to recurrent and perhaps painful injury. Besides this inconvenience, it is abnormally liable to malignant change and to torsion, and may lose its power to produce spermatozoa. Consequently there is general agreement that remedial measures are demanded by the displacement itself apart from any coincident lesions such as hernia or hydrocele.

Hitherto the task of cure has been left almost entirely in the hands of surgeons, and the operative treatment has been of three kinds—excision, displacement into the abdomen, and induction into the scrotum. The desirability of excising a unilateral misplaced testis may be urged on the ground that the aberrant organ has an enhanced liability to neoplasia. On the other hand, the liability is not very great, and nowadays the feeling is decidedly against so drastic a course. An argument used in former days to justify excision was that the organ was useless as shown

by microscopical sections. MOORE's recent work¹ may be recalled in this connexion. Experimenting on rats, guinea-pigs, dogs, rabbits, and sheep, he found that if a testis was pushed into the abdomen and retained there by closure of the inguinal canal, the seminal epithelium degenerated quickly and completely, but the interstitial tissue was unaffected; there was reason to attribute this destructive process to the increased temperature of the interior of the abdomen as compared with that of the scrotum. MOORE further discovered that the degeneration of the seminal epithelium was reversible, and that if the testes were replaced in the scrotum their capacity for spermatogenesis would be regained. Such observations on the effects of malposition in animals can hardly be ignored when removal of a maldescended testis in a human being is under contemplation. They have proved that the undescended testicle is a useful organ because the interstitial tissue, in which male hormones are elaborated, remains unimpaired and so can maintain sexual potency and the male characteristics; furthermore they show that even fertility may be restored if the testicle be brought down into the scrotum. The former, but not the latter, end is also served by the second operation recommended—replacement of the organ in the abdomen. This should preserve interstitial secretion, and it has also been claimed that a testis lying in the abdominal cavity is less likely to undergo neoplastic changes than one lying in the inguinal canal. The third operation, the ideal to which the surgeon will aspire, is the transportation of the misplaced testicle to its proper position well down in the scrotum. The successful accomplishment of this aim will not only protect the patient from the recurrent injuries and discomforts associated with an incompletely descended testicle, but will place the gland in a position where it may regain its spermatogenic function. Advances in technique, such as those described by Mr. D'ARCY MCCREA in our issue of Oct. 5th, have led to a continual improvement in the results obtained by operative treatment and a far higher standard of success is now attained by surgery than was attained twenty years ago. Yet we must still admit that the results are often disappointing. It has been estimated, indeed, on the basis of several hundred cases, that in only half was the operation successful as judged by the final position of the testicle, and in only about 15 per cent. did the organ ultimately reach a normal size.²

Happily an alternative form of treatment is now available which holds out the prospect of curing the deformity in half or more of the cases without any kind of surgical operation. Experiments on animals have shown that the maturation of the testis which precedes its descent is controlled by the "gonadotropic" hormone of the anterior lobe of the pituitary, and the new treatment consists in administration of large quantities of such hormone (prolan) by way of belated substitution

¹ Moore, C. R.: *New Eng. Jour. Med.*, 1935, cexil, 422.

² Burdick, C. G., and Coley, B. L.: *Ann. of Surg.*, 1926, lxxiv, 567.

therapy. While in the uterus the foetus is subjected to the gonadotropic hormones present in the maternal blood, and it is probably for this reason that in man and the higher apes as well as in some other animals the testes are already in the scrotum at birth. Almost immediately after birth these hormonal influences become negligible, and if the testicle has not already reached the scrotum it may remain undescended until it once more comes under the influence of an increased supply of gonadotropic hormones either at puberty or at the period of rut. An apparently reasonable working hypothesis would be that failure of the testis to descend in some human infants is attributable to a deficiency in the supply of gonadotropic hormone before birth. The matter, it is true, may not be quite so simple as this. Another hormone, oestrin, is abundant in the blood of the pregnant woman and has entry into that of the foetus, and when oestrin is administered in suitable dosage to immature rats and mice it prevents the testes from maturing and causes a failure in their descent. Hence it seems possible that the primary defect responsible for failure of descent might either be a deficient supply of gonadotropic hormone, or an excessive supply of oestrin, or these two factors combined. However, seeing that from birth until puberty the individual will not naturally be subjected to the influence of these hormones, and that even at puberty they may fall short of requirements, it seems reasonable to supply the child temporarily with adequate amounts of gonadotropic hormone, and so to reproduce in part at least the hormonal conditions to which the normal child is exposed in the uterus. Theory apart, the method has now been used by a number of clinicians with a high proportion of good results. This week we print a paper by Dr. SPENCE and Dr. SCOWEN of St. Bartholomew's Hospital, who have been pioneers in England of this form of treatment, and it will be seen that their results compare favourably with those of surgery. Recent observations on schoolboys in the United States³ suggest that we may have been in the habit of underrating the frequency with which late descent of the testicle occurs spontaneously; but even so it is hard to suppose that the changes recorded among SPENCE and SCOWEN's 33 patients were natural phenomena unassociated with the treatment employed. The striking advantage of the new mode of therapy is that if it succeeds the patient will be cured, both functionally and anatomically, without incurring any persistent and unpleasant mementos of his cure; while if it fails the outlook for surgical operation will be as good as before if not better. On the other hand, if an operation is unsuccessful it may disturb the anatomy of the inguinal region in such a way as to vitiate the chances of subsequent improvement with hormone. Once the testis is laid in the scrotum it may be expected to undergo a complete restoration of functional competence, and though the possibility of subsequent neoplasia

remains a source of anxiety, it is comparatively slight and is attendant on any form of treatment which includes preservation of the testis. It seems possible that this risk is in some degree proportional to the period during which the testis has been misplaced, and if this is so an additional advantage of treatment by hormones is that infancy is not a bar to its employment.

No one will suggest that the last word has been said on the treatment of the undescended testicle. Many details of the new technique have yet to be settled, including the optimum intervals between successive administrations, the size of the dosage, and the precise nature of the hormone used. Nevertheless it does appear as though, in one more field of pathology, we are within sight of a rational and satisfactory therapeutic measure.

THE VARIABILITY OF MAN

HUMAN beings, it may be argued, do not differ from each other in the kind of innate abilities and characteristics they possess but only in the degree to which they possess them. There are many physical characteristics in which obviously the differences can only be in degree—for instance, height, weight, blood pressure, and pulse-rate. When we come to mental capacities the position is far less clear. Is the difference between a moron and an ISAAC NEWTON only a quantitative difference which can be adequately measured on a scale of intelligence quotients? In other characteristics we may suspect quantitative differences, but we can apply no measuring rod to them. For example, people seem to vary in their susceptibility to specific diseases; it is probable that here a large number of factors are at issue; we cannot at present isolate them and we cannot measure them. Even to-day, however, the variability of man in his physical, physiological, or mental characteristics is not of merely academic interest. Without a considerable knowledge of it we cannot determine where the "normal" is likely to shade off into the "pathological." Thus in a valuable study¹ of blood pressure in healthy males of 18–40 years of age, Dr. PETER MCKINLAY and Dr. A. B. WALKER found in 566 physically fit men a variation in the heart-rate at rest from a minimum of 46 to a maximum of 129, in the systolic blood pressure from 97 to 168, and in the diastolic from 46 to 108. The more extreme measurements are, naturally, very uncommon, and the major proportion of the cases fall within much narrower limits—for instance, 69 per cent. of the heart-rates lie between 62 and 86. The variability of physiological measurements such as these, MCKINLAY and WALKER conclude, is not sufficiently recognised either in standard textbooks or in clinical teaching. Too often reliance is placed upon average values, and ignorance prevails as to the range of values compatible with health.

An interesting monograph² on the variability

¹ Edinburgh Med. Jour., 1935, xlii., 407.

of the many and various characteristics of man has recently been produced by Mr. D. WECHSLER, Ph.D., chief psychologist of the psychiatric division of the Bellevue Hospital, New York City. The material he presents, "combed from what may be termed the farthest corners of periodic literature," covers a series of linear traits such as stature, length of head, and length of leg; metabolic constants such as body temperature, duration of pregnancy, and sugar in blood; circumference measurements of the chest, neck, and thigh; physiological functions such as the respiratory rate, pulse-rate, vital capacity; the weight of the body and its organs; motor capacities such as speed of running and swiftness of blow; and perceptual and intellectual abilities. The list of characteristics is long, but with the exception of such traits as height, weight, vital capacity, and one or two others, few of the capacities of man have been measured at all extensively. WECHSLER estimates the degree of variability by means of the "range ratio" of the 2nd to the 999th observation in order of magnitude, concluding, on empirical grounds, that the two extreme cases constitute the pathological or abnormal group. On this basis he finds that the range ratios of man's capacities seemingly fall into natural groups or hierarchies. Thus the ratios of nearly all the linear traits fall between 1:22:1 and 1:40:1 (mean 1:30:1), those pertaining to motor functions from 1:65:1 to 2:50:1 (mean 2:33:1), those of perceptual and intellectual abilities from 2:30:1 to 2:85:1 (mean 2:58:1). Numerically, and in comparison with the enormous ranges to be observed in nature, the limits of the variability of man are exceedingly small; though, clearly, small quantitative differences can, and do, give rise to very important qualitative differences. Thus our description of the difference between a genius and an average person by a statement to the effect that he has an intelligent quotient greater by this or that amount, does not, in WECHSLER's words, describe the difference between them as completely or in the same way as when we say that a mile is much longer than an inch. The genius not only has an intelligent quotient of, say, 50 points more than the average person but "in virtue of this difference acquires seemingly new aspects (potentialities) or characteristics, which produce a 'qualitative' difference." The interpretation that WECHSLER advances for the qualitative differences in the genius is that they are the result of transformations consequent to the passing of certain critical points of achievement assumed to exist in all human capacities—analogueous to the transformations that occur in material substances at certain critical points of pressure and temperature, where small changes in cause may produce striking changes in effect. As one of the rarest of all gifts he defines the ability of the genius to perceive new relationships—that is, relations which however obvious or easy to master after they have been discovered, are yet imperceptible to the mass of mankind before their discovery.

In one of his chapters WECHSLER tries to reach

a satisfactory conclusion on the thorny problem of the relation of age to mental virility. For physical measurements, measurements of strength, motor functions like swiftness of blow, and certain perceptual abilities, the data collected by GALTON nearly half a century ago, and more recently analysed in detail by RUGER and STOESSIGER and by ELDERTON and MOUL, still constitute the most extensive observations by age on any considerable number of characteristics. The general trend of these with age may be summarised as an initial rapid rise, a gradual slackening as adult life is approached, a maximum value round about 24-25 years, and then—a feature not previously fully recognised—a very definite decline at first imperceptible but more conspicuous as age increases. GALTON's investigations did not include any growth studies of intellectual abilities, and as evidence of such WECHSLER quotes the intelligence scores of over 15,000 Army officers of the U.S.A. and the results of intelligent tests applies to American civil populations by various workers. From this material he draws the conclusion that the "intelligence" growth curve differs very little in its general trend from the typical growth curves of physical, physiological, and psychomotor abilities. "Contrary," he says, "to popular anticipation, the point of optimal achievement in the case of intelligence occurs rather earlier than it does in the case of at least a large number of physical and physiological capacities. There is still some growth in intelligence after fifteen which is now generally accepted as the approximate age at which the intellectual capacities cease to grow; but what is even more striking than this is that after twenty-five (or at most thirty) our intellectual capacities are definitely on the decline, and, just as in the case of physical strength, continue to fall off progressively with age." This is a somewhat bitter pill to swallow; but perhaps the older among us can console ourselves with the thought that what we lose on the swings we may gain on the roundabouts. For native ability is not the only factor in practical life; tested knowledge and experience may be equally important, and when the former is on the downward path the latter are on the upward.

THE MINISTRY OF WOMEN

AN event is historically important if its immediate consequences are great or if the considerations behind it embody a new and profound idea. The report¹ of the Archbishops' Commission did not recommend the admission of women to the priesthood, but it will, we may predict with confidence, be regarded in future times as a turning point in ecclesiastical history, because the Commissioners have taken the revolutionary step of admitting the evidence of psychological medicine on the unconscious forces in mental life.

"Psychology throws some light on the strong feeling that is aroused by the suggestion that women

¹ The Ministry of Women. Report of the Archbishops' Commission. London: The Press and Publications Board of the Church Assembly, Church House, Westminster, S.W. 1. Pp. 90. 1s.

should be admitted to the priesthood. This emotion affords evidence of powerful subconscious motive, acting both in those who support and in those who oppose such proposals. It is especially significant that the admission of women to the ministry of the sanctuary should so often be regarded as something shameful. From evidence submitted to us we are driven to the conclusion that this sense of shame is very largely based on a non-rational sex-taboo" (pp. 34-35).

There is an appendix of special importance since it summarises the evidence on the clinical side and the significance which should be attached to it. The suggestion that women should be admitted to the status and function of priesthood rouses in many people a strong feeling either for or against the proposal. It was evident to the Commissioners that the strength of this emotional feeling, conjoined with a wide variety of often contradictory rational explanations, was due to powerful and widespread subconscious motives, and that the lack of objectivity (arising from ideas of male dominance and feminine inferiority) is to be traced to subconscious ideas of woman as "man manqué," which have their background in irrational infantile conceptions that persist subliminally in adult life.

The importance of this document historically

lies in the fact that the Church for the first time recognises these unconscious irrational infantile conceptions as determinants of adult behaviour, in this instance in respect to sex antagonism and an attitude to religion. The appendix states:—

"One of the factors in determining the restriction of the Christian priesthood to men had undoubtedly been the inevitable correlation of the Eucharist with the sacrifices of pagan religion and of Judaism, which took place in the second and third centuries. But this only confirmed the operation of deeper motives, wholly unconscious, and infantile in character, which were operative in Christianity as strongly as elsewhere" (p. 82).

This is the point where science and religion make effective contact. The rational arguments advanced by Voltaire and later by the biologists of the nineteenth century did not touch the central fact that religion ministers to the deepest needs of the individual and produces a sense of harmony which the science of those periods in no way understood. The fact that the rulers of the Church now turn to psychological medicine indicates not only that science proves helpful in dealing with the Church's problems, but that it is now dealing in its own way with the same material as the Church—the inner life of man.

ANNOTATIONS

EVERYDAY PHILOSOPHY

UNDER the energetic direction of Mr. Sidney Hooper the British Institute of Philosophy has now reached its tenth year and many of our readers will feel sympathetic interest in the letter printed elsewhere in this issue. The institute does at least two useful things. It provides each year an admirable course of lectures by distinguished men who are worth hearing, and it begs us to believe that philosophy is something which should find expression in our common lives and not an abstract study for students with a habit of mind remote from their fellows. It does more than this, but these items perhaps are all that the ordinary professional man will feel able to bend his attention to. Human interest can hardly have a better aim than to arrive at as clear a distinction as may be between right and wrong, and the natures of good and evil have occupied many minds and will no doubt continue to exercise more. They have this stability that everyone agrees that we should avoid evil and do good; the difference of opinion has been over the question as to what is good and what evil, and as the criterion has continually been shifting and, as has often happened, what was deemed good has been found to be bad, so trivial consideration has been liable to think that the practical distinction between them is uncertain. That right and wrong are not absolute qualities of items of conduct must seem fairly obvious to anyone who has absorbed the idea of evolution, and it encourages us to think hopefully of man's progress to reflect how rarely a "wrong" deed has been transferred to the "right" category, and to wonder uneasily how much evil we still count as good. But to recognise frankly that there is a drift from one list to the other is no justification for a belief that there is no real distinction between the lists. This is one of the fundamental principles of

which the letter from the council of the institute speaks; it does good service if it helps sober-minded people to think over such things more carefully.

OXYGEN THERAPY

THE offer of the British Red Cross Society to provide oxygen tents of the type devised by Dr. E. P. Poulton for clinical trial at the London teaching hospitals¹ was a welcome indication of increasing interest in the more efficient methods of oxygen therapy. Since then a similar policy has been announced by the London County Council² which has agreed to make a special grant towards the expenses of Dr. Poulton's investigation and to purchase two of the latest pattern oxygen tents to be stationed at Hammersmith and Lewisham Hospitals where they will be available for use at any L.C.C. hospital. It would hardly be an exaggeration to say that the methods of oxygen administration generally used in this country have been so ineffective as to reduce this form of therapy to little more than a pious gesture. Much wider use has been made of oxygen therapy in America. This is reflected in the commercial production of several varieties of oxygen tent apparatus, and of special aids for nasal catheter administration of oxygen; and in the provision of oxygen chambers in many large American hospitals.

Of these three effective and clinically applicable methods, the oxygen chamber would naturally be expected to be the most effective, when available. This expectation is justified by the experience of A. L. Barach,³ who reports a lower mortality in cases treated in the chamber than in those treated by the nasal catheter or the tent. The initial and upkeep costs of such a chamber are high, and it can obviously be available only in a large hospital. The nasal

¹ THE LANCET, Sept. 21st, 1935, p. 691.

² Annual Report of the Council for 1934. Vol. IV., Part I. Public Health: General and Special Hospitals, p. 20.

³ New York State Jour. Med., 1934, xxxiv., 41.

catheter method has the advantage of cheapness and ready availability. It is reasonably efficient if the tip of the catheter be introduced as far as the oropharynx,⁴ and an adequate flow of oxygen maintained. Barach⁵ and Barker et al.⁶ have shown that a flow of 5 litres per minute will maintain an effective concentration of about 35 per cent., even with a raised respiration-rate. The catheter should have several perforations near its tip and the oxygen must be passed through warm water to avoid painful desiccation of the pharyngeal mucosa. Several combined flow-meter and humidifier devices are commercially available in America; none is at present produced in this country, and efficient nasal catheter administration is rarely effected. There is no doubt, however, that oxygen can be more efficiently administered by a properly designed tent than by the best nasal catheter device. Finality has by no means been attained in tent design, as a survey of the various designs available will show; and it is possible that with increasing experience, useful modifications will increase the clinical usefulness of these devices. At present, we understand that the chief difficulty is the fact that enclosure in the apparatus often seems to have an unfavourable psychological effect on the patient. In the experience of some hospitals this sensation is so intense that a patient can hardly be induced to remain in it. A minor, but real, addition to this difficulty in the past was the unpleasant smell of rubber which tends to emanate especially from a new tent: this may well be eliminated in the most modern tents. Finally, the nursing of a patient in the tent is undoubtedly a difficult problem. Favourable results following the use of their tent in treatment of a variety of pulmonary and cardiac conditions have been reviewed by Argyll Campbell and Poulton in their recent book. The available data on "Oxygen and Carbon Dioxide Therapy" suggest that the tent has been of more value in broncho- than in lobar pneumonia. This finding is in accord with theoretical considerations based on the pathology of these two forms of pneumonia. In cardiac failure it appears that more improvement is observed in cases of failure due to arterio-sclerotic disease than in those due to rheumatic disease. In cases of congestive cardiac failure reacting favourably to prolonged oxygen therapy, relief of dyspnoea and diminution of anoxæmia are almost immediate, and a fall of venous pressure, accompanied by diuresis, is observed. In this country, favourable results of treatment in Dr. Poulton's tent have been recorded in cases of bronchitis and emphysema with circulatory failure, cyanosis after pulmonary lobectomy, and broncho-pneumonia complicating whooping-cough. In very young infants the psychological troubles do not of course arise, and it is of interest that some of the most favourable results in pneumonia have been observed in infants. After such serious thoracic operations as lobectomy or thoracoplasty, the patient has to contend not only with shock but also with a local injury to the respiratory bellows; and in these cases the use of the tent in the first few days after operation may well save life.

There has been a tendency to pay insufficient attention to the late results in oxygen therapy. If these are considered, it becomes apparent that it is in such conditions as the immediate post-operative period in major thoracic surgery, and in the pneumonia of infants, that the treatment is likely to be most

efficacious, judged by the criterion of permanent restoration to useful life. Temporary improvement undoubtedly follows in some cases of chronic disease, such as arterio-sclerotic heart failure and pulmonary fibrosis, but cannot be expected to be maintained on return to normal atmosphere. In London the tent may prove especially useful during fogs, not only providing a high concentration of oxygen but also acting as a local air-conditioning plant. In an investigation dealing with patients ill enough to require oxygen administration for relief of anoxæmia, it is well-nigh impossible to provide satisfactory controls. It is greatly to be hoped, therefore, that the combined experience of clinicians in the London teaching hospitals with the oxygen tents rendered available by the British Red Cross Society will provide a basis for a reasoned appraisal of the value of this method of treatment.

THE SHERRY PARTY

THE practitioner of medicine, like the Roman poet, finds nothing which concerns his fellow man without interest for himself. Often he may disapprove of customs and habits practised by those about him, but at least he is bound to be well acquainted with them. Otherwise he will many a time fail to understand the nature of the patient in his hands, even if he is not actually at a loss to read his physical condition correctly. Thus that recent social phenomenon the sherry party is worthy of attention from the practitioner, at any rate if he practises in a great town, for we believe that the new habit has not so closely affected country districts, where people are still wont to take tea with one another. In London the sherry party has to a great extent ousted the tea party. Reasons for this are obvious enough. First, so many people to-day, both men and women, have some occupation which takes up their time too deeply to leave them free for any social engagement in the early afternoon. When work is over they can go gladly enough to the sherry party, and thus the habit, which started only after the war, becomes increasingly popular as more of us become workers and fewer of us have leisure until late in the day. Further, the sherry party enables the entertainment of a large number of friends at a comparatively small cost, bringing together heterogeneous company to whom it is charming to be hospitable, and people nowadays cannot be indifferent to the expense of entertainment. But what of these parties looked at by the medical eye? Are they as well founded—hygienically and dietetically—as they are on social and economic grounds? The first-sight verdict would be undoubtedly "no." The party generally consists of a large number of men and women crowded into a room not intended for half the assemblage. An estimate of the oxygenation and the movement of the atmosphere of the apartment would no doubt condemn it wholeheartedly as not up to standard. Nor do we believe that the dietitian would give unstinted approval to the little sausages, the various forms of cheese biseuit, and the disguised anchovies which are being consumed in the intervals between sundry glasses of light or dark sherry, or both. But we must not overlook the psychological side of the sherry party. Here there is much to be said in its favour. They happen at a time of day when the worker is most ready for and most favourably affected by refreshment. He and she are often tired. A little alcohol brings about a quick and a full effect, which is supported by the small but supporting amounts of food

⁴ Wineland, A. J., and Waters, R. M.: Arch. Surg., 1931, xxii., 67.

⁵ Jour. Amer. Med. Assoc., 1929, xciii., 1550.

⁶ Loc. cit., 1934, ciii., 244.

eaten at the same time. Conversation and cheerful feelings come easily. People seem more attractive than usual, and return to dinner from the party probably none the worse for its crowded atmosphere, and certainly all the better for its many mental contacts.

EPIDEMIC DROPSY

AMONG the most interesting problems of tropical medicine is epidemic dropsy, a mysterious malady which, owing to its resemblance to oedematous beri-beri, has been thought to bear some relation to that avitaminosis. An opportunity for further research presented itself to the energetic investigators of the School of Tropical Medicine, Calcutta, in a widespread and alarming epidemic which started in Purulia in August, 1934. This is a district which has been visited several times previously by the disease. A house-to-house census showed that 2000 persons out of a population of 25,974 had been affected during the current year, while in the surrounding villages another 5000 cases were revealed. As on previous occasions, in other places, the disease was found to be chiefly prevalent amongst the upper and middle classes, and a distinct familial tendency was noted, though the severity of symptoms varied considerably in members of the same family, who took exactly the same food. Rice was the staple diet, and Lieut.-Colonel R. N. Chopra and Dr. R. N. Chaudhuri,¹ who conducted these investigations, are able to show that among the better class the rice required for the year's consumption is prepared from the paddy after the harvest and is stored in the houses, whereas the labouring classes are paid in kind, from day to day, with paddy, which they husk into rice for immediate use. Another difference is that the better classes throw away the rice water, whilst the poorer drink it. Rice collected from different families in various localities showed that many grains (50–80 per cent.) in every sample had central opacities, while samples of mustard oil, which is popularly held to be the cause of the epidemic disease, were found to be mostly adulterated.

The following clinical observations are based on 66 cases examined in detail. The sex distribution was approximately equal, but the disease was not seen under four years of age. Preliminary diarrhoea was common, the stool containing some mucus and blood. Palpitation was also common, enlargement of the heart was noted in 14 cases and breathlessness on exertion in 26. Most of the patients had tachycardia (pulse-rate 90–140), and the pulse pressure was usually raised. The one constant sign was oedema, and it followed the diarrhoea. As a rule it did not spread above the knee, but sometimes the sacral regions and hands were affected. A rash on the legs and thighs (vascular or erythematous) was observed in 14 patients, and angiomatous nodules or sarcoids in 4; increased pigmentation on the forehead and cheeks was also seen. There was fever in the acute stage. The deep reflexes were normal in 57 cases, increased in 5, decreased in 3, and absent in 1 only. Reports from many villages showed that the illness caused abortion in every pregnant woman. In treatment the following measures were found effective: a rice-free diet; rest; initial purgation; and the administration of tincture of ephedra (20–30 minims) with 10 grains of calcium lactate three times daily. The main ocular complications of the disease have been studied by Lieut.-Colonel E. O'G. Kirwan,² who puts first among them glaucoma of the primary

non-inflammatory type. The canal of Schlemm and the tissues in the immediate vicinity exhibited no abnormality on section, either in cellularity or in increased fibrosis, and there is no evidence of any inflammatory process to be found in the whole of the uveal tract. Aqueous humour removed from the anterior chamber has been shown to contain a toxic "H" substance resembling histamine in its action, and Kirwan suggests that this may be produced from specific micro-organisms in the alimentary tract. Other pathological aspects have been studied by M. N. De and K. D. Chatterjee.³ The ecchymotic patches of the skin are found to consist of vascular telangiectases rather than actual hæmorrhage into the tissues. The dark-red cutaneous warty growths and nodular excrescences arising from the superficial portion of the skin have the structure of a capillary angioma. The development of these growths is not confined to the skin, and they may appear on mucous surfaces, such as the gum, cheek, and interior of the nose and tongue. The cutaneous manifestations, which appear to vary from one epidemic to another, have been made the further subject of clinical study by Chopra and Chaudhuri, who illustrate their papers⁴ with coloured drawings. In the heart the chief changes, which lead to heart failure, are the separation of the muscular fibres by enormously dilated intermuscular capillaries.

The results of these investigations point to the rice-toxin theory as being the most tenable. In the present state of knowledge there is some justification for placing epidemic dropsy among the bowel diseases, and it seems highly probable that the syndrome has nothing to do with diseases caused by vitamin-B deficiency.

THOMAS LOVELL BEDDOES

THERE have been recently many signs of a more general interest in the poetry of Thomas Lovell Beddoes, and he can be included in the category of medical men who have made a mark in general literature, although his actual professional career was slight and accidental. So much so that in his biography⁵ very little reference is made to his medical career, and it becomes clear that some of the allusions one has occasionally seen to him previously, and this after a biography had been written by his lifelong friend Thomas Forbes Kelsall, have been made through careless confusion between Thomas Lovell Beddoes the poet and his father Thomas Beddoes the doctor. The father enjoyed a high and in many directions well-deserved reputation as physician and physiologist, and his "Hygeia" is quite worth consultation to-day for the range, psychological insight, and sound theories with regard to education to be found therein, but he was not a poet. Nor was Thomas Lovell Beddoes a doctor save in name. Probably the father's reputation influenced the son to make an excursion into practical medicine, and the learning thus acquired permeates much of his poetical work. Personal influence by the father, apart from piety, to a memory can hardly have occurred, as the father died when the son was five years old, but his mother, the sister of Maria Edgeworth, was a highly cultivated woman. The boy went to Charterhouse, and both there and at Pembroke, Oxford, wrote poetry, much of his early work being written as an undergraduate, while some of his first efforts date from his school days. He had not actually graduated at

¹ *Ibid.*, p. 489.

² *Ibid.*, pp. 493 and 496.

³ Thomas Lovell Beddoes, the Making of a Poet. By H. W. Donner, B.Litt., D.Phil. Oxford: Basil Blackwell. 1935. Pp. 403. 18s.

⁴ Indian Med. Gaz., September, 1935, p. 451.

⁵ *Ibid.*, p. 485.

Oxford when he began his famous work "Death's Jest-Book," upon the perfecting of which he was engaged for over 20 years, and he died in circumstances that remain unexplained before its publication. While still at Oxford in 1825 there appeared another of his great poems, "The Bride's Tragedy," modelled on the dramas of the Jacobean period, whose terrors and splendours were the source of his serious inspiration. Prefacing Mr. Donner's biography will be found an excellent résumé of the condition of the stage in England in the early nineteenth century as regards tragedy, and this critical survey explains why Beddoes went back to Webster, Marston, and Cyril Tourneur for his ideals as to drama and his guidance as to planning his work. In 1825 came the sudden inclination towards medicine. While still *in statu pupillari* at Oxford he went to Göttingen University and remained there four years studying physiology, chemistry, and surgery, making, however, a return to Oxford to take his degree in arts. After this he continued his medical studies at Würzburg University where he eventually obtained the degree of doctor of medicine. His political sympathies, however, made it difficult for him to reside in Bavaria, and he fled the country before his medical degree was actually conferred, although later he assumed the title of M.D. and actually practised a little in Frankfort. The right to claim Thomas Lovell Beddoes as a medical man is thus established, but his fame, which has steadily grown, depends entirely upon his poetical productions. These⁶ have now been published in as complete a form as possible, and all scholars will be indebted to Mr. Donner for this excellent edition which includes the full version of "Death's Jest-Book" with parallel texts of earlier versions and various readings. The production of the book has been made possible by the generous assistance of many possessors of manuscripts and records, and should spread the fame of Beddoes while showing how it has occurred that, while always a poet's poet, he has obtained no popular fame. These two books should right the neglect, and Mr. Donner's biography deserves the real praise that is also due to his editing of the poetic corpus. And if Beddoes can hardly be claimed as a doctor, it becomes abundantly clear from his later writings that he drew freely upon medical learning.

TUBERCULOSIS IN ITALY

IN all parts of the civilised world the mortality from tuberculosis has in recent years declined substantially. This is agreed, but there is less agreement whether the decline is due to the activities of public health authorities, an improved standard of living, an epidemic periodicity in incidence or virulence, or, as must seem probable, a conjunction of many circumstances. Italy is no exception to the rule. Dr. A. Lutrario, late director-general of the public health, shows in a report to the Permanent Committee of the Office International d'Hygiène publique that its mortality-rate from tuberculosis has declined from over 200 per 100,000 inhabitants in 1887-89 to about 90 in 1934, or by over 50 per cent. The improvement in the past 15 years has been particularly rapid, following some deterioration over the years of the late war. It has been seen in both sexes and at all ages though not equally. The greatest decline has been in the first five years of life, the

rate at those ages in 1930-32 being less than a third the rate registered in 1900-02, while the least improvement is shown at ages 45-64, which over the same period of time amounts to only 18 per cent. Except in young adult life, when females are peculiarly susceptible, the fall in the death-rate has been more favourable to females than to males. If attention is concentrated on the last decade it is seen that the registered deaths have fallen from 60,000 to 35,000, and this in spite of the increase in the population, increased industrial development, and better facilities for accurate diagnosis. Lutrario prevents too much satisfaction being derived from these figures by pointing out that tuberculosis in Italy still occupies fourth place in the causes of death. Much remains to be done and he reports a new step to be taken—viz., "a national week for early diagnosis." This year 300,000 children have been examined clinically and radiologically by 3000 medical men. By such a measure it is proposed to detect all who are affected in the rising generation at the earliest possible moment and to bring about a lasting cure. The task is obviously a vast one and the results will be watched with interest. War with its inevitable economic distresses and the withdrawal from the population of the most physically fit section of the males leads invariably to a rise in the mortality from tuberculosis. It is sincerely to be hoped that the vigorous efforts that Italy is adopting against the disease will not be offset by such causes.

THE MAURICE CRAIG MEMORIAL

IN another column will be seen an influentially signed letter bringing before the public as well as the medical profession the claim of Maurice Craig to a permanent memorial as a pioneer in the treatment of nervous and mental illnesses. We hope that our readers will acknowledge the justice of the claim and will do their best to promote so worthy a movement. Craig was a great mental specialist who from the beginning of his career as an exponent of psychological medicine showed an unusual blend of scientific and worldly wisdom. His work at his hospital—he was consulting physician in psychological medicine to Guy's Hospital—and as specialist bore alike the imprint of his practical experience and his ability to retain from a wide range of reading the best of what he learned. He wrote a manual on his subject in which he showed an enviable mental poise, being able to reconcile the wisdom of old teaching with the advances in new and conflicting theories. And his great contribution to the therapeutics of his subject was his insistence on the intimate relations between general and psychological medicine and the work of the educationist. This was the subject of the Maudsley lecture delivered before the Royal Medico-Psychological Association, and was elaborated in certain directions in the Bradshaw lecture delivered before the Royal College of Physicians of London when he dwelt upon the close relationship of the systems of the body and the dangers of specialism.

It was this liberal attitude of mind which made Craig somewhat impatient of certain modern psychological work, so that the significance which he attached to the physical health of mental patients made him sometimes to appear content with advocacy of the old maxim "the healthy mind in the healthy body"; but his views were founded on a range of experience which entitled him to hold them, and as a personal adviser he was remarkably successful. "His power of throwing the whole of himself into the particular

⁶ The Works of Thomas Lovell Beddoes. Edited with an introduction by H. W. Donner. London: Humphrey Milford, Oxford University Press. 1935. Pp. 834. 25s.

troubles of the individual which gave him his wonderfully understanding and strengthening sympathy combined with his charm, were invaluable assets in gaining the confidence and affection of patients." Thus the letter in our columns, and there is not a syllable of exaggeration in it. Apart from his work of a purely professional character the public positions which Craig filled with marked success deserve an enduring memorial. He was the principal agent in forming the National Council for Mental Hygiene, and was instrumental in the foundation of the Cassel Hospital for Functional Nervous Disorders, a scheme made possible by the coöperation of Ernest Cassel. He was a member of the War Office committee on shell-shock, and it was in great part due to him and Sir Farquhar Buzzard that the theory became accepted that the mind was vulnerable as well as the body; in other words, that shell-shock formed a part of the casualties of modern warfare and that the victims should receive treatment from that point of view. The form which it is proposed that the Maurice Craig memorial should take is truly appropriate. He would himself certainly have approved of the foundation of an established centre for the activities of the National Council of Mental Hygiene, and we hope that contributions to the fund now being started will materialise promptly. Dr. Eric Wornum (121, Harley-street, London W.1) is acting as honorary treasurer to the movement.

THE PRACTITIONER IN FACTORY LIFE

In the House of Commons on Monday Mr. Lovat-Fraser called the attention of the Home Secretary to the increase last year in the number of accidents to young persons in factories. There were 21,000 accidents in 1935 against 17,000 in 1934, an increase which Mr. Lovat-Fraser was inclined to attribute to lack of concentration brought about by long hours of work. In replying for the Home Office, Mr. Geoffrey Lloyd said that the increase of accidents in 1934 applied also to adults, both, he thought, being due mainly to more extensive employment consequent on greater industrial activity. This had admittedly led in some cases to longer hours, but how far fatigue had contributed to accidents among young persons he was not in a position to say. He reminded the House, however, of the Prime Minister's promise to introduce in the second session of this Parliament a Bill to revise and consolidate the Factory Acts. The imminence of this long threatened Bill adds importance to the meeting reported elsewhere (p. 1387). The Association of Certifying Factory Surgeons, which has its headquarters in Manchester, met in London this year, possibly in recognition of the settled trend of industry away from the industrial north to the home counties. The certifying factory surgeon may be the oldest medical official, but in spite of that has remained for over 90 years a general practitioner of medicine; and this is as it should be, for he has to deal not with things but with persons. The entrants into industrial life are the school-leavers whom he already knows; being appointed by the chief inspector he is no creature either of employer or employed, but rather an impartial agent to bring the resources of medicine to bear on those entering industry, an aim for which an ex-Home Secretary present at the meeting had a specially good word. There is general recognition of the need for bridging the break between school and industrial life and for keeping watch on the health of the young worker for some time at all events after he has entered industry. When the text of the new Bill is made public it will presumably take account of these things.

The certifying factory surgeon will then gain a more effective hearing for the fruits of his experience if his Association is fully representative. At present the membership does not include more than 20 per cent. of the personnel, although we understand that during the past year efforts to increase the membership have met with good response. His office is increasingly important even if, as was remarked at the meeting by one of the oldest of them, the standard set by Whitelegge and Legge is not easy to live up to. In some respects the system of practitioner certifiers and Home Office inspectors may be heterogeneous, but it has worked well in practice and we trust that the principle will be maintained. To this end it would be desirable for the Association to redouble its efforts towards unity during the period that remains before the Bill is introduced.

MERITS AND DEMERITS OF CYCLOPROPANE

ANÆSTHETISTS had the opportunity last week of seeing cyclopropane in use in the afternoon and of discussing it in the evening. The demonstration at the Cancer Hospital on Dec. 6th of two abdominal operations, for which, after a small dose of omnopon, cyclopropane was the sole anæsthetic used, was highly satisfactory. The apparatus employed by Dr. Stanley Rowbotham was simple, with soda lime in the rebreathing bag. In the evening he read a paper at the section of anæsthetics of the Royal Society of Medicine embodying the substance of his recent communication to our columns,¹ the discussion on which elicited a general opinion that the two chief disadvantages of cyclopropane are depression of respiration and increase of bleeding. Dr. I. H. Magill, whose experience of the drug is considerable, values cyclopropane chiefly for severe chest operations, in which its non-irritating nature is a great help. He thought it difficult to say to what extent the arrest of respiration was due to absorption of carbon dioxide and to what extent to cyclopropane. Dr. Frankis Evans drew attention to peculiarities in the urine found after cyclopropane inhalation. The urine was orange coloured and in two-thirds of the patients urobilin was found to be present; although this pointed to liver damage, the patients had recovered without apparent hindrance. Dr. Langton Hewer did not think that cyclopropane would play a big part in general anæsthesia, but deemed it of great value in special conditions; among these he placed thyroidectomy in patients with bad heart risks. Dr. Rowbotham drew attention to the heightened blood pressure which was commonly associated with cyclopropane anæsthesia. Mr. H. Hepworth, D.Sc., pointed out the chemically innocuous nature of cyclopropane, which was now being made at Manchester by Imperial Chemical Industries Ltd., and was available for anæsthetists at a cost no greater than that which had to be paid in America. It was not likely ever to be as cheap as nitrous oxide.

WE regret to announce the death of Mr. Walter Sydney Perrin, surgeon to the London Hospital, which occurred on Dec. 8th. An obituary notice will appear next week.

THE sixth International Congress of Physical Medicine will be held in London from May 12th to 16th, 1936, under the presidency of Lord Horder. The hon. secretary is Dr. A. Eidinow, 4, Upper Wimpole-street, W.1.

LXXX.

PROGNOSIS OF PITUITARY TUMOURS

II*—Visual Loss

It is visual loss more than any other symptom that leads patients with pituitary tumour to seek treatment. What are their prospects of retaining their sight? Prognosis, as well as diagnosis, depends on accurate charting of the visual fields, not only on the perimeter but also on the Bjerrum screen where central vision, which is much more important to the patient than any other part of the visual field, can be adequately tested. When once the tumour begins to press on the optic chiasm and produce visual symptoms there is every prospect that without treatment the patient will sooner or later become blind; there may, however, be periods of spontaneous improvement, especially in the early stages, when one eye is often much more affected than the other, and, when once the stage of complete bitemporal hemianopia is reached, the loss of sight may appear to be stayed even for years.

While every certain case of chromophobe adenoma that comes under observation has loss of vision, acromegaly may sometimes exist for years without any disturbance of vision. Of 12 acromegals at present under my care, 4 have no appreciable disturbance of vision that can be attributed to the tumour, or only the slightest depression of the upper temporal fields. Of the other cases 2 had acromegaly for ten years before visual symptoms came on. Radiograms of the sella turcica may provide useful information on this point: when the sella tends to be closed above, either by the narrowness of its entrance or by the firmness of its diaphragm, a condition suggested by disclosure of calcified interclinoid ligaments (the so-called "bridged" sella), then the chiasm is fairly strongly protected from the expanding tumour and there is probability, but by no means certainty, that operation on account of visual symptoms may never be necessary. It is best that such patients should be kept under regular observation by quantitative perimetry.

OPERATION FOR VISUAL DISTURBANCE

X ray treatment may be effective in relieving the visual disturbance of some acromegals but not of patients with chromophobe adenoma. For most cases operation is necessary; it is usually done now by the transfrontal route, and the operative mortality has been 8 per cent. in my series of 50 cases, though the experience thus gained should bring a lower mortality. Cushing ("Intracranial Tumours," Springfield, 1932) in his latest series of 59 cases had a mortality of 6.8 per cent. When the pressure on the optic chiasm is of short duration there is every prospect that partial removal of the tumour by operation will effect what is, for practical purposes, complete restoration of all parts of the visual field, though a slight degree of bitemporal hemianopia to colours can still be demonstrated. Even when the pressure upon the optic chiasm is intense, excellent recovery of vision will be obtained by operation provided the symptoms are of short duration. One of my patients, who was completely blind with pupils fixed to light before operation, could read 6/9 with one eye four days after operation. In this

case the patient had had a mild degree of visual disturbance for some months and had then gone rapidly blind a few days before operation; after operation what was recently lost was rapidly regained, whereas the earlier loss of sight was not recovered from. This is a typical result of operation to relieve pressure on the optic chiasm. There is no intracranial tumour that so consistently repays early surgical intervention as a pituitary adenoma that has begun to press upon the optic chiasm seriously enough to interfere with the vision of one or both eyes. The risks of operation are now sufficiently small, particularly in early cases, to justify the claim that temporising is inadvisable, even when spontaneous improvement has occurred. Almost every patient with pituitary tumour undergoes during his course towards blindness one or more periods of spontaneous improvement in sight. In cases in which visual acuity has been reduced to less than 6/60 in both eyes for any considerable period of time, and in which vision is limited to a part of the nasal fields, operation offers little prospect of recovery of useful sight; though I have seen once in such a case a remarkably good recovery of sight after transphenoidal operation, a recovery that was maintained over a long period of years.

While the duration and the degree of the visual loss are of prime importance in prognosis, additional information of great value can be obtained by *quantitative perimetry*. By this method the visual acuity not only of the macular region but of the whole extent of the visual field can be determined, and, naturally, areas in which the largest object or a strong light is not perceived are not so likely to recover as those in which such objects are seen. Areas of relative blindness, or "depressions" as Traquair calls them, that have sloping edges are more likely to recover after operation than those that have steep edges. Disproportion between the extent of field in which a white and coloured object of equal size can be perceived is also to a certain extent unfavourable for prognosis. Patients in whom only the more central parts of the field are depressed while vision is still preserved in the peripheral parts of the field (the scotomatous type of bitemporal hemianopia) usually make a very satisfactory recovery of sight after operation.

RISKS OF OPERATION

The risks to life are greatest in those cases in which the tumour is very large, particularly where the tumour extends into the brain. After operation by the transfrontal route smell is lost at one nostril, owing to pressure and traction on one olfactory tract and bulb, but this does not incommode the patient. Occasionally, however, both olfactory tracts are damaged during operation and then smell is permanently lost or severely impaired. Excessive thirst and polyuria are frequent in the first few days after operation, but in my experience these symptoms always subside spontaneously. I have had one case in which left abducent paresis was present for six weeks after operation. Four patients developed mental symptoms after operation, and in one, an unbalanced woman of 68, these symptoms were permanent. One patient had slight aphasia for a few days after operation, probably from interference with an extension of the tumour into the left temporal lobe.

* Part I. appeared last week.

OPERATIVE RESULTS.

In my series of 50 cases 4 died after operation. In 6 cases vision was not improved by operation but was not made worse; these were cases in which the loss of sight had been coming on for a long period of time and had become severe. In one case vision, which had been reduced to something near blindness for some months by a large chromophobe adenoma, was completely lost after an operation which had been conducted gently and without any obvious injury to the ribbon-like optic nerves. In 39 cases vision improved after operation, often dramatically and with complete disappearance of subjective hemianopia, though some depression of the temporal fields could still be displayed by suitable tests. Improvement of vision usually occurs within the first few days after operation, and probably any improvement that occurs after three weeks is due to delayed shift of a tumour as a result of the operation rather than to immediate relief of pressure on the optic nerves and chiasm at the time of operation.

In my series the recurrence-rate has been high,

as judged by regular perimetric observations extending over several years. Thus 9 patients have shown further visual loss. Of these 1 has been relieved by X ray treatment and 4 others by a second operation; in 2 others a second operation failed to improve vision, and 2 others not operated on are slowly getting worse. These recurrences were for the most part not due to rapid growth of tumour but to the incompleteness of the removal of tumour at the original operation, usually because of inherent difficulties of a large neglected tumour, but sometimes owing to error of surgical judgment. It is likely that the incidence of recurrence would be greatly reduced by more radical extirpation of the tumour, but with greater risk of life. Pituitary tumour is a disease that destroys sight rather than life, and therefore the risks to life of operative treatment must be reduced to the lowest possible dimension. A further period of useful sight can often be obtained by a second operation.

HUGH CAIRNS, M.B. Adelaide, F.R.C.S. Eng.,
Surgeon to the Neurosurgical Department,
London Hospital.

SPECIAL ARTICLES

GENERAL MEDICAL COUNCIL

WINTER SESSION, NOV. 26TH-DEC. 3RD

(Continued from p. 1325)

New Penal Cases.

CHARGES OF DRUNKENNESS

The Case of Archibald Miller, registered as of 79, Bent-road, Hamilton, M.B., Ch.B. 1928, U.Glasg., who had been summoned to appear before the Council on the following charge:—

That being a registered medical practitioner: (a) You were convicted (1) on June 4th, 1934, at the Sheriff Court, Hamilton, of using a motor-car without a policy of insurance in respect of third-party risks being in force in relation to such user, and were fined £2, or 14 days' imprisonment; (2) on July 11th, 1934, at the Sheriff Court, Hamilton, of driving a motor-car without due care and attention, and were fined £1, or five days' imprisonment; (3) on June 17th, 1935, at the Justice of the Peace Court, Hamilton, of assault and breach of the peace, and were fined £2, or 20 days' imprisonment; (4) on Oct. 10th, 1935, at the Sheriff Court, Hamilton, of driving a motor-car whilst under the influence of drink, and were fined £5, or 30 days' imprisonment, and disqualified for 12 months from holding or obtaining a driving licence. (b) On March 11th, 1935, while visiting Mrs. Hoey for the purpose of attending her on her confinement, you were so far under the influence of drink that you were unfit to attend or treat the patient. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

Dr. Miller was accompanied by Mr. O. Hempson, solicitor.

Mr. Winterbottom put the facts before the Council and called Mr. John Hoey, who testified to his statutory declaration, which described how respondent had attended his wife in her confinement, in company with her own doctor and a hospital sister. Respondent had returned alone later in the night very drunk, and had tried to force his way into the house. Nearly three weeks afterwards witness had seen the other doctor again for the first time.

In reply to Mr. Hempson, he said that a policeman had called on him and taken him to swear his declaration and to identify respondent. He had not com-

plained to the police or anyone else, but understood that Mrs. Beattie, the woman looking after his wife, had been to the police office to telephone and they had heard about it in that way. He had been disappointed when respondent had returned alone, without the doctor chosen for the confinement. He described the second visit in detail. The waiting woman had suggested to him between the two visits that the other doctor had taken drink and witness was looking out for something wrong. Witness was convinced that respondent was drunk on the second occasion, but not on the first. He had gone away quite well when witness said he would get the police.

Mrs. Isabella Constance Beattie, the woman in attendance on Mrs. Hoey, testified to her statutory declaration describing the two visits. She had seen nothing wrong at the first visit, but an hour later he was staggering and his speech very thick. She had left to telephone for another doctor. Later she had identified respondent. In reply to Mr. Hempson, she said the police inspector had prepared the declaration for her. She was being paid to attend Mrs. Hoey and thought the other nurse had no right to be there, as it was her case. On the second occasion the nurse had entered the house before the doctor; she had come in to fetch the doctor out; witness had not been there at the time. On the first occasion she had thought the other doctor was drunk and had told Mr. Hoey so. In reply to a member of the Council, she said she was not a certified midwife.

Dr. Miller, examined by Mr. Hempson, said he had not realised his car was uninsured, though he was technically guilty of the first offence. He had no idea the policy could be cancelled without his permission. The Legal Assessor observed that the policy had been cancelled on March 16th and the offence had been committed on April 9th. Dr. Miller, continuing, said he had protested. The second charge was that of passing a flash-light about midnight on a stormy night; he would not stop for anyone at that time of night. The assault had been technical; he had not had any animus against the man, an imbecile to whom he was in the habit of giving alms. The man had rushed at him and witness had pushed him away saying "Here's sixpence. Go away."

Mr. Hempson put in a declaration from a doctor at the Crichton Royal Institution where respondent had been an in-patient for some time this summer suffering from neurasthenia.

Witness then described how Mrs. Hoey's doctor had taken him round to the patient's house. He had been accompanied by his fiancée, a certified midwife to whom he had just become engaged. He had had two glasses of Graves before his meal, and about three single whiskies before calling on the other doctor, but no more at all after. The other doctor had a septic thumb and witness had offered to take the case for him. His fiancée had gone in with him. Finding the patient needed no attention at that time, he and his fiancée had waited outside the other doctor's surgery for over an hour and had then taken him to his garage and returned to the Hoey's house. His fiancée and brother had been with him all the time and they had had no drink whatever. Mr. Hoey had been rude and had accused him of smelling of drink and staggering, and had said he had wanted his own doctor. He had then returned to the other doctor's house, and then paid a visit to an old family friend and finally gone back home by car. He had found a message awaiting him and had gone out and visited the patient.

Answering Mr. Winterbottom, he agreed that he had had a letter from the insurance company offering a rebate in exchange for withdrawal, but had thought they could not do it. His illness had not been in any way due to drink, but only to strain and worry. He had had the Graves about 5 p.m. and the whiskies about 7 p.m. Answering the Legal Assessor, he maintained that his condition on the second visit was just the same as on the first. Mrs. Beattie had not spoken to him. His fiancée had not entered the house on the second occasion. Mr. Hoey had not mentioned the police at all. Answering Dr. Bone, he said he had got home about 11.30 p.m. after driving his car about 25 miles, and had garaged it himself and got it out again, driven to the patient, about a mile and a quarter, and back, and garaged again—all without any assistance.

Mr. Neil Campbell Miller, respondent's brother, said he had been a motor driver and tester of other drivers in the army during the war. He had accompanied his brother and his fiancée in the Austin Seven car. Respondent had been perfectly sober throughout the evening and quite capable of driving the car. His driving had been perfect. Witness was dead against anyone driving a car if he had had drink.

The witness answered questions put by Mr. Winterbottom, the President, and the Legal Assessor, and said he would have gone home on a bus if respondent had stayed at the Hoey's for a long time. Actually he had only been inside a minute or two. His fiancée had called him from the car, but had not left the car at all. Witness had not heard what took place.

Mr. Hempson read two statutory declarations from the other doctor, who described the visits to the Hoey's house and declared that Dr. Miller was perfectly sober. He had asked Dr. Miller's help because of a whitlow. He had refused to go back to the Hoey's house, being indignant, and had never been sent for again. Another declaration from the family friend said that respondent was perfectly sober when he visited her. A fourth was from a gentleman in the garage adjacent to that of Dr. Miller; he had spoken with Dr. Miller when he put his car away and found him perfectly sober and able to negotiate the difficult entry to the garage. The

next declaration was by the patient whose wife Dr. Miller had visited about midnight. He also had found the doctor perfectly sober without signs of having taken drink.

Mr. Hempson and Mr. Winterbottom addressed the Council, which then deliberated in camera. The President announced that the facts in charge (b) had not been found proved. Those in charge (a) had been proved to the satisfaction of the Council. Judgment had been postponed, subject to the usual provisos, until November, 1937. Dr. Miller would be required to forward testimonials before the 1936 session, when he was advised to attend.

The Case of William Garraway Smith, registered as of 2, Cardiff-road, Newport, Mon., M.R.C.S. Eng. 1932; L.R.C.P. Lond. 1932, who had been summoned to appear before the Council on the following charge:—

That being a registered medical practitioner you have by means of an agent canvassed for the purpose of obtaining patients in respect of your practice as a registered medical practitioner carried on by you at Newport, Mon., and in particular on or about Feb. 18th, 1935, canvassed: (1) Mrs. Rhoda Lyle Hookham, of 110, Maesglas-avenue, Newport; (2) Mrs. Gwladys Jane Dodd, of 104, Maesglas-avenue, Newport; (3) Mrs. Mary Shorney, of 84, Maesglas-avenue, Newport; (4) Mrs. Smith, the wife of Alfred William Smith, of 128, Maesglas-avenue, Newport; all of whom were patients of John Joseph Crowe, a registered medical practitioner. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The complainant was Mr. John Joseph Crowe, L.A.H. Dubl. 1919, who appeared in person. Respondent was represented by Mr. T. Carthew, counsel, instructed by Messrs. Le Brasseur and Oakley, on behalf of the London and Counties Medical Protection Society.

Dr. Crowe said that until January last he had been the only resident practitioner in the industrial district of Maesglas. Then Dr. Smith had opened up a practice. Complainant had told him, in a friendly conversation, that he had a family club, as it was essential in the district; the fee was 6d. Soon after he had received numerous complaints of a door-to-door canvass. Respondent had said he did not believe in family clubs but he was canvassing for a club at 4d. a week. Complainant had rung up Dr. Smith and asked about an alleged canvasser named Wallace; Dr. Smith had denied that Wallace was working for him. Nevertheless the man had continued approaching people with cards in his hands, urging people to join Dr. Smith's cheaper and better club. Dr. Crowe declared he was not vindictive or jealous.

Mr. A. W. Smith testified to his statutory declaration describing how a man with a number of cards in his hand had gone to every house down the street and had asked his wife to join Dr. Smith's club. Cross-examined by Mr. Carthew, he said he had overheard the conversation and gone to the door. The canvasser had died on May 2nd, 1935. In reply to members, he said he had seen the cards since but not at the time; Mr. Wallace was quite a friend of his.

Mrs. R. L. Hookham and Mrs. E. Gummy testified to their statutory declarations, giving similar evidence.

Mrs. Gummy had received a green card which Mr. Wallace had signed, and next week she had tried to withdraw, but he had continued to try to persuade her. Answering Mr. Carthew, she said she had mislaid the card. She did not remember going to Dr. Smith's surgery to ask about her teeth. She

was not sure when Wallace came to her but thought it was in February. She had not gone to the surgery and joined the club there. She had been in the surgery recently, but had paid the fourpence at the beginning of the year to the canvassers, not to Dr. Smith.

Dr. Crowe put in a statutory declaration from Mrs. Dodd, who had been present on Saturday, giving similar evidence.

Dr. Smith, examined by Mr. Carthew, said he had been born in Newport where his parents and grandparents had lived. He had first practised there as a dentist, and then had qualified as a doctor, and later set up in practice a few hundred yards away from Dr. Crowe. He had gone to Newport because it was his and his wife's family home, but at first had not intended to practise there. He could produce letters showing that he had negotiated to buy practices elsewhere up to the end of February, 1935. On Dec. 27th, 1934, Wallace had called in a very agitated state and asked respondent to see his child. Respondent had advised him to go back to Dr. Crowe, but the Wallaces refused and said they would go to another doctor altogether. The child had been seriously ill but had recovered. The parents had been most grateful, and Wallace had wanted to help respondent, who had said he could collect debts for him. Respondent had started a club about Jan. 26th for a limited class of patients only. Wallace had collected about 3s. 6d. in book debts and had been given a list of the eight or nine club patients. He had been definitely forbidden to canvass, in the presence of his wife and others, and had been shown the Council's warning notice. When Dr. Crowe had rung up he had begun by saying: "You bloody swine, I'll get you out of this district." For the moment witness had not known who was speaking. About five minutes after the first call Dr. Crowe had rung up again, in a cooler mood, and said he would report the matter to the Council if there was any more canvassing. Respondent had denied the charge and had tackled Wallace about it. Wallace had denied it, and had offered to go and see Dr. Crowe about it. Respondent repeated his warning but accepted Wallace's word that he was not canvassing and allowed him to go on collecting. He had stayed on in Newport because of Dr. Crowe's threats. The green cards had been delivered about Jan. 31st, and were kept in an unlocked surgery drawer whence Wallace might have taken them, but he had no authority to do so. His original club book showed Mrs. Gummy's name in his own handwriting as having paid 4d. in the surgery on Jan. 26th. She had first asked about some teeth and then asked to join his club if he had one.

In answer to the Legal Assessor, he said that Wallace had worked for him unpaid until he entered hospital in April.

Dr. Crowe cross-examined Dr. Smith, who identified a green card with his name and Mr. Wallace's initials on it.

Mrs. Smith confirmed her husband's evidence. She had never seen any cards.

Mrs. Wallace, widow of Mr. E. Wallace, related the story of her child's illness as told by Dr. Smith. They would not have gone back to Dr. Crowe anyway. Dr. Smith had saved the baby's life and her husband had wanted to do all he could for him. She remembered Dr. Smith telling her husband not to canvass anybody under any circumstances. In reply to Dr. Crowe, she said he had visited the baby four times—not seven—but she had never said the baby was much better. Her evidence was not

what Dr. Smith had told her to say. Mr. G. W. Lidgett, chemist, remembered that Dr. Crowe early in February had purchased a few things and remarked that Dr. Smith had decided to stay in the district, but he (Dr. Crowe) had got the previous doctor out and would get him (Dr. Smith) out. He also recalled Feb. 12th when Dr. Smith had warned Mr. Wallace not to canvass, and had shown him a greenish-coloured paper saying, "Read this, Wallace." Witness had read the words "Notice" and "Medical Council" on it. In cross-examination he denied having ever spoken about Dr. Smith's canvassing to Dr. Crowe.

Mr. W. H. Curle, garage proprietor, said his wife and baby had been patients of Dr. Smith in February. He had gone to the surgery for medicine and found Mr. Wallace there. Mr. Wallace had talked to him, praising Dr. Smith very highly and saying he would do all he could to see the doctor was well patronised. Dr. Smith had come in and rebuked Mr. Wallace and warned him about canvassing. He had added that he did not want more patients as he was negotiating for a practice elsewhere. Mr. Wallace had said he would not do it any more.

Mr. Carthew put in four statutory declarations and addressed the Council. After Dr. Crowe had argued his case the Council deliberated in camera and the President announced that the Council had not found the charges proved.

Removal from Register at Practitioner's Request

The Executive Committee reported that Mr. Jean Braun and Mr. R. B. Sidebottom had applied for the removal of their names from the Medical Register on the grounds that they had ceased to practise; and Mr. J. A. Quin for private reasons. The Standing Orders having been complied with and the Royal Colleges concerned having no objections, the applications of Mr. Braun and Mr. Sidebottom were granted but that of Mr. Quin was referred to the Council with the recommendation that it be not acceded to in the absence of any evidence that he had ceased to practise.

MEDICINE AND THE LAW

A Mother is not a Parent

SOMEWHERE near the law courts is stabled the phantom coach with four horses which is driven from time to time by the judges through Acts of Parliament. By some such equestrian feat the court has lately decided that the word "parent" in the Education Act does not include the mother. Section 87 enables the local education authority to direct its medical officer to examine in any public elementary school the person and clothing of any child. If the child or its clothing is found to be verminous or in a foul or filthy condition, written notice may be given "to the parent of the child, requiring him to cleanse properly the person and clothing of the child." If the parent allows the child to get into such a condition that it is again necessary to proceed under the section, the parent is liable to a fine not exceeding 5s. No special emphasis need be placed on the word "him" in the passage already quoted from the statute. The Interpretation Act, which saves the draftsman trouble in many directions by automatically introducing into all statutes various compendious descriptions and constructions, expressly states that, unless the contrary intention appears in a statute, words of the masculine gender shall include

females. The draftsman therefore does not bother to say "him or her"; he need only say "him." There happens to be a special definition of "parent" in Section 170 (12) of the Education Act; it states that the word is to include a guardian and a person liable to maintain or having the custody of the child, but it nowhere states that "parent" in Section 87 or otherwise shall exclusively mean a male parent. In a recent case before the Catford magistrates the London County Council had been obliged to proceed against a parent under Section 87. Last December the child was removed from the school and its person and clothing were properly cleansed. In February the child was again in a condition requiring cleansing and the L.C.C. took action against the mother. The L.C.C. argued that "parent" in Section 87 includes the mother, whether or not the father of the child is living with her, and that the local authority has a statutory right to proceed against either parent at discretion. The Catford justices held that, where the father was not absent from the home, he is liable to be charged as being the person who has *de facto* custody and control. The justices dismissed the information and the Divisional Court has now ruled that they were right. A previous decision, on which the judges relied, was that of *Woodward v. Oldfield* in 1928. That case concerned a mentally defective child who was required to be sent to a special school. The father happened to be serving a sentence of penal servitude from which he would not be released for another five months. In the circumstances the judges decided that the mother really was the parent after all. The court noted that if proceedings were taken against the father by the county council for the failure to comply with the direction to send the child to the special school the poor man could but reply that he was unfortunately engaged elsewhere and unable to attend to the matter. It would be grotesque, said Lord Hewart, to call the father the parent in these circumstances.

Some circumstances, then, such as the permanent absence of the father in prison, can justify the county council in treating the mother as a parent. Is not the local education authority meant to use its discretion in the light of the circumstances? May not other circumstances, such as the daily absence of the father during working hours, justify the council in proceeding against the other parent? Presumably the county council moves against the particular person in a particular household who is deemed the most suitable object from the point of view of enforcing the law. The Catford case restores the old-fashioned predominance of the male sex which has been so drastically diminished in the past twenty years. In matters like the guardianship of infants the mother's legal rights are now but little inferior to the father's; it would startle many mothers if they were told that they had not *de facto* custody and control of their children. As for statutory liabilities, there used to be a presumption that, where husband and wife had together broken the law, the wife must have been coerced by her husband; this old doctrine of coercion has been formally abolished. Masculine responsibility for income-tax is a deplorable survival. The Catford decision is another anachronism. Though law is not biology, a declaration that mothers are not parents is the highest of ascents into the stratosphere of judicial ignorance.

Paternity Dispute—Colour of Child's Eyes

More human, perhaps, than legal interest is aroused by Reuter's account, published in the *Evening*

Standard last week, of a Copenhagen case where a husband repudiated the paternity of a child because of the colour of its eyes. His contention was that he himself was blue-eyed and so was his wife, and their respective ancestors had been blue-eyed for several generations; the child in question was brown-eyed, and he argued that it was "impossible" that he could be the father. He made no dispute until the child was 13 years old; but he then applied to the courts for an order to relieve him from liability for the child's maintenance and to restore to him previous payments in that respect. The court is reported to have consulted medical experts and to have obtained the views of the Danish Ministry of Health. Although it was stated that the chance of a brown-eyed baby being born to blue-eyed parents was only one in a hundred, the court accepted the mother's evidence that her husband (the complainant) was the father of the child. The husband was ordered to continue his contributions and to pay the costs of his application.

CONGRESS OF RADIOLOGY

UNDER the presidency of Dr. L. A. ROWDEN, the ninth annual congress of the British Institute of Radiology was held from Dec. 4th to 6th at the Central Hall, Westminster. In delivering the Silvanus Thompson lecture Mr. G. W. C. KAYE, D.Sc., took occasion to review the advances of the past forty years.

Forty Years of Radiology

They have contained, he said, scientific wonders and achievements in plenty; after Röntgen's discovery of X rays came J. J. Thomson with the electron, Becquerel with radio-activity, the Curies with radium, Rutherford with atomic disintegration, and recently a new coinage of quanta, protons, photons, and neutrons—all in forty short years. The Röntgen Society (incorporated in the British Institute of Radiology) was founded in 1897, and was the first society started in any country with the object of studying X rays. The first journal in the world to be devoted exclusively to X rays was founded in April, 1896, under the title of *Archives of Clinical Skiagraphy*; it is now the *British Journal of Radiology*. Silvanus Thompson, founder of the Röntgen Society, gave his presidential address on Nov. 5th, 1897, quoting Shakespeare's prophetic words:—

"You go not until I set you up a glass
Where you may see the inmost part of you."

It is difficult for the younger generation, he continued, to appreciate the state of the art of the radiologist in the early days. Thanks largely to the pioneer work of Bowers, the X ray tube of to-day is self-protected and shock-proof; the whole equipment is earth-shielded throughout, permits precise control, and is silent in operation. Many have devised circuits made up of various groupings of transformers, condensers, and rectifying valves which yield constant high voltages or pulsating high voltages that can be progressively increased above that of the output voltage of the transformer. The hot-cathode rectifier has almost replaced the mechanical rectifier, mercury-vapour rectifiers are now available, and copper-oxide rectifiers have been introduced for dealing with the currents obtainable in deep-therapy outfits. Higher and higher voltages for therapy seem to be the order of the day and a notable contribution to equipment is due to Allibone and his collaborators who have constructed auto-

matically evacuated X ray tubes and valves which are self-protected, shock-proof, and operated by a press-button.

Much work also has been done on the measurement of dosage. The barium platinocyanide pastille has been long employed as a dosimeter; it has been possible to show that a pastille is capable of giving dosage results with reasonable accuracy over a range of qualities of X rays excited by voltages from 50 to 150 kv. But all recent work has been on air-ionisation methods as affording the most suitable basis for sufficiently accurate measurements and it can be assumed that they do provide a physical measure of the energy absorbed in tissue and probably therefore of the biological effect. At the Stockholm Congress in 1928 the röntgen was formally adopted, and much has been done on its practical realisation. In the case of the X ray region so far examined the secondary electrons are effectively absorbed in the volume in which they are liberated; thus the definition of the röntgen, as regards the full utilisation of secondary electrons, can be met for a restricted beam of X rays by using either (a) adequately large "free air" parallel-plate chambers, or (b) small closed "air-wall" chambers which prescribe the irradiated air volume, the walls of the chamber being composed of materials of the same effective atomic number as air. It is worthy of note that in 1931 an international comparison of the röntgen, as realised by the free-air standard chambers of the Bureau of Standards, the Reichsanstalt, and the National Physical Laboratory, resulted in agreement within 0.5 per cent. for X rays generated at voltages between 100 and 150 kv. In the case of gamma rays of radium investigations are in progress on the possibility of realising the röntgen in the gamma ray region.

In the measurement of quality of X rays in everyday practice there has not been much advance beyond the half-value layer method introduced by Christen about 1913. Spectral analysis, whilst unsurpassed in the laboratory, is not a method adapted to the radiologist's needs. Of the radium standards the British consists of 15.60 mg. of pure anhydrous radium chloride. This replaces the first national radium standard deposited at the National Physical Laboratory in 1913 which had formed the basis of test of 122 g. of radium.

Certain general truths concerning radiation therapy seem to be emerging, particularly as to the types and situation of the growths suitable for treatment. As to the quality of radiation required, deep lesions and gland areas seem to necessitate the use either of radium in large quantities (bombs) placed at a distance, or of X rays of high output, which, excited by very high voltages, approach the gamma rays in quality (400 kv. outfits are in operation at Lambeth and the Cancer Hospitals and sets employing substantially higher voltages are being installed at St. Bartholomew's, the Middlesex, and Hammersmith Hospitals). The radium bomb aims at the massive depth doses possible with X rays, and there is a growing belief in the efficacy of "tele-radium-therapy" reflected in the increasing number of large radium units being set up; an 8-gramme unit in Paris, a 5-gramme one in Stockholm, several 4-gramme units in the United States of America. The Radium Beam Therapy Research Board in this country is now fostering one or more 5-gramme units.

Reference to X ray diagnosis is hardly necessary, so spectacular has been its progress. But it should be mentioned that Russell Reynolds's success in X ray cinematography will in all likelihood prove

a great step forward in the investigation of the physiology, anatomy, and pathology of moving structures.

In a period of 40 years, said Dr. Kaye in conclusion, the British Institute of Radiology and, before it, the Röntgen Society have initiated and carried through much work of both national and international significance and have established fine traditions. Men like Archibald Reid, Robert Knox, and Stanley Melville gave unstintingly of their time and energies, and the part they played will long be remembered.

Diagnostic Radiology

The medical communications to the congress were classified under therapeutics and diagnostics. Dr. G. E. Vilvandré, Dr. R. McWhirter, and Dr. J. Struthers Fulton spoke on various aspects of radiotherapy and papers on diagnosis were given by Dr. M. H. Jupe, Dr. E. W. Twining, and Dr. R. Fawcitt.

Dr. JUPE, dealing with *ventriculography*, pointed out that replacement of the cerebro-spinal fluid by air is not without its dangers; severe reaction in the form of intense headache and vomiting is not unknown, and the procedure must therefore not be undertaken lightly. He showed many instructive ventriculograms, demonstrating enlargement, displacement, or non-filling of the ventricular system, according to the site of the lesion.

Dr. TWINING's subject was *gastro-intestinal neoplasms*. The vast majority of gastric growths, he said, are cancerous, and the characteristic X ray findings are the presence of a filling defect in the shadow of the barium-filled stomach, local rigidity of the area involved, alteration in the mucosal pattern, and six-hour gastric retention, although there may be initial pyloric insufficiency and rapid emptying. In the body of the stomach special note should be taken of the edge of the filling defect: it is abrupt and sharply defined from the adjacent healthy area; on the lesser curvature it must be remembered that a shallow crater deformity may be due to malignancy, the crater deformity being due to encroachment by the growth on the lumen of the stomach. A not uncommon sign of carcinoma of the lesser curvature in the prepyloric region is the presence of a flat shadow above the main part of the stomach shadow, an appearance due to growth holding some of the opaque medium; it has been termed the "meniscus" sign. In hypertrophic pyloric stenosis in adults, of which several cases have been reported, there is a variable narrowing of the pylorus together with the absence of a palpable tumour—valuable points in the differential diagnosis from carcinoma.

Dr. FAWCITT, speaking on *fungoid infections of the lungs*, drew attention to possible infection from damp hay. The vast majority of fungi are, as far as is known, non-pathogenic to man but some are pathogenic and it is probable that in the future more will be added to the latter class. It is necessary to bear in mind that many fungi are abundant in air and that samples of sputum exposed to air may be contaminated; also that fungi are fairly common in the saliva (the patient should gargle and rinse his mouth before being asked to cough and expectorate his specimen of sputum), and that even if the fungus is present it may be non-pathogenic. Among the agricultural population of Westmorland several cases had been found all presenting somewhat similar symptoms—viz., dyspnoea on slight exertion, cough, and some expectoration. In each case the symptoms came on comparatively soon after working with

dusty hay. Tubercle bacilli were not present in the sputa. Radiographically the appearances were those of a fine mottling throughout both lung fields, the apices being clear, together with a considerable degree of emphysema. After treatment with potassium iodide the X ray appearances had altered, the shadows becoming more sharply defined and fibrosis being more evident. Dr. Fawcitt brought forward these cases with the idea of emphasising that where the clinical symptoms and signs are suggestive of pulmonary tuberculosis and yet on repeated examination no tubercle bacilli are found in the sputum the possibility of a bronchomycosis should be considered if the patient is an agricultural worker.

The Mackenzie Davidson lecture was this year given by Dr. G. HARRISON ORTON, who took as his subject Calcium Changes and their Importance in Diagnostic Radiology.

The Exhibition

As usual the exhibition of apparatus attracted many visitors to the Central Hall. This year there has been no revolutionary advance in design or practice, but minor improvements in the construction of the various units was evident. Shock-proof tube cases are smaller; shock-proofing of apparatus is now standard. There is a tendency to increase the output of mobile units suitable for ward work, one being available to give 60 m.a. at 90 kv. A stereoscopic teleradiographic unit aroused much interest, the cassette changer and the tube-shift being electrically controlled. On one stand were noted a urological radiographic couch and a motor-driven radiographic couch in which castings had not been employed, all suitable metal parts having been welded. Nowadays a steady improvement in the design and capabilities of the motor-driven tilting table is to be expected, and it was this year conspicuous. A feature of the exhibition is always the fine collection of skiagrams shown on the film manufacturers' stands; apart from their technical quality many of these films are of great medical interest and provide an opportunity for informal discussion.

The annual dinner of the congress was held at Claridge's on Dec. 6th.

PARIS

(FROM OUR OWN CORRESPONDENT)

B C G

Of the two latest reports on B C G to be presented to the French Academy of Medicine the first concerns the Casba quarter of the town of Algiers, with a population of more than 40,000. The vaccine has been given by the mouth to new-born babies in this quarter since 1926; and in the three-year period 1931-33 about every other child born (2393 out of a total of 4260) was thus inoculated within the first ten days of birth. The general mortality, it is stated, was 29 per cent. higher among the controls than among the inoculated. Figures from Athens, as interpreted by their sponsors, are even more favourable to B C G. Between April 14th, 1925, and April 14th, 1935, 7351 babies were inoculated with B C G, which in 6813 of these cases was given by the mouth on birth. The elder children were given B C G either by the mouth or by subcutaneous injection. The conclusions to which the Greek observers come are (1) that B C G inoculation is harmless; (2) that it should be supplemented by the isolation of the new-

born from possible sources of infection for a certain time; (3) that the morbidity among the B C G children due to "anergising" ailments (presumably such diseases as measles) is less by one-third than that of the controls; and (4) that the general mortality of inoculated children from the age of one month to six years is six times less than that of the controls.

TYPHOID AND UNDULANT FEVER IN FRANCE

In a survey of the infectious diseases notified in France last year, Dr. A. Lemierre¹ urges the health authorities of the different departments to simplify their reports by adopting a uniform system of presentation. Some of these official reports, it appears, are still hand-written. All the 88 departments sending in health reports refer to the presence of typhoid fever in their midst. The most important source of this infection, to judge by the frequency with which it is mentioned, is the polluted well. The consumption in the raw state of shell-fish by the seashore is another potent source of infection; and in spite of official interdiction, the sale continues of shell-fish collected in forbidden areas in the proximity of sewers. In Toulon, for example, typhoid fever is endemic and causes some 30 deaths every year because of this reprehensible practice. Seaside summer visitors need to be taught that their amateurish invasion of the shell-fish domain and their consumption on the spot of whatever they can pick up are fraught with danger. The comparative immunity from typhoid and paratyphoid fever enjoyed by ex-soldiers who have undergone compulsory inoculation against these diseases does not seem to have made the civilian population clamour for their own protection by this means, or even passively allow it. Oddly enough, combined inoculation against diphtheria, typhoid, and paratyphoid fever proves more acceptable; the public strains at the gnat, but does not mind the camel.

Undulant fever is evidently spreading and its existence has now been notified in as many as 42 departments. And as some of those failing to notify a single case are in the most highly infected areas, the immunity enjoyed by them must be more apparent than real. Formerly, undulant fever was limited to the south of France, whereas now it has invaded the east and centre. The organism commonly infecting human beings in this country is the *Brucella melitensis*.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

THE PROBLEM OF WATER POLLUTION

WITHIN the last two years most of the States have set up planning boards, some of them appointed by the governor, others established by act of the legislature. The work of these State planning boards is coordinated by a National Resources Committee in Washington. On most of the State boards public health is represented by the State health commissioner or by his sanitary engineer. It is natural therefore that the subject of stream pollution by human and industrial wastes has not been neglected. Recently published reports of the National Resources Committee lay emphasis on water pollution as one of the major water problems facing the States.

¹ Bull. de l'Acad. de Méd., 1935, cxiv., 304.

The New Jersey board reports that for many miles their streams are so badly polluted that all thought of their recreational use has long since been abandoned. A study made on the Upper Mississippi by Minnesota and Wisconsin shows that "the annual loss to commercial fishing and clamming through water pollution is \$95,000; the annual damage to sport fishing and attendant industries is \$35,000; while decreased property values in the Twin Cities was estimated at \$2,000,000, and damage to lands for recreational purposes at \$1,500,000." The Missouri State Planning Board finds that pollution of its streams is not yet heavy enough to endanger fish life or to create a nuisance, but that it is placing an ever-increasing load on water purification plants in cities depending upon the rivers for their water-supply. Colorado notes that "it is significant that certain land areas in Colorado situated between two river valleys and not subjected to contaminating influence of polluted streams experience relatively low death-rates from water-borne diseases, showing thereby that stream pollution may justly be recognised as a dangerous menace to life and health."

The national committee summarises the dangers to human health as follows:—

"Water-borne diseases are likely to be spread by use of contaminated water for domestic purposes or the irrigation of crops, or for bathing, boating, and fishing, or for the production of ice supplies which later come in contact with food or drinks that are consumed without being cooked. Dairy animals having access to polluted streams present a public health hazard for they may easily pick up disease-producing bacteria on their bodies which are transferred mechanically to the milk."

They add that the protection of water used for municipal water-supplies and recreation is urgent in virtually every State. Rather strangely their report fails to remark that the pressing problem in one State may be the result of an offence in another State. Thus the most serious pollution in New Mexico is that of the Animas river which carries large quantities of untreated sewage from the city of Durango in Southern Colorado across the State boundary. The doctrine of "States Rights" upon which the United States Constitution is based, and which is still regarded by most Americans as sacred, makes the solution of such problems difficult.

INADEQUATE SEWERAGE

Almost every State board has made a study of sewage disposal. In Maine 100 towns were asked for a report. Of those replying 55 per cent. said that they had sewerage systems; of the remaining 45 per cent. without public sewerage many have private sewers that empty into the streams. In Kansas the sewage of 46 per cent. of the urban population is returned to the surface water-supply either untreated or treated inadequately. Population centres comprising a total of 8,393,000 people discharge untreated sewage into the waters of New York State. In Minnesota only 121 of the 256 municipal and 24 large institutional sewerage systems have sewage treatment plants. Denver, the largest city in the Rocky Mountain belt, containing 28 per cent. of the population of Colorado, has no sewage treatment plant. Since the Colorado planning board made its report however, Denver has voted a bond issue to meet this situation.

The disposal of industrial wastes often creates greater difficulties than the disposal of sewage. Too great severity on the part of the State may result in economic loss and unemployment. The Texas

board reports as a particularly difficult problem the disposal of the salt water brought to the earth's surface by the drilling operations of the petroleum industry.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE "ACUTE ABDOMEN" IN CHILDHOOD

At a meeting of the Edinburgh Medico-Chirurgical Society last week Sir Lancelot Barrington-Ward read a paper on the diagnosis and treatment of acute abdominal conditions in children. Of 278 cases of "acute abdomen" admitted to Great Ormond-street Hospital, London, in the last five years, 41·8 per cent. proved to be acute appendicitis, 37·6 per cent. intussusception, 7·7 per cent. intestinal obstruction, and 7·7 per cent. peritonitis; the remainder were rare conditions. Erroneous diagnosis, Sir Lancelot said, would be avoided by not expecting every case to present all the typical features; in particular the symptoms produced by inflammation of a "concealed" or "pelvic" appendix were often misleading. A waiting policy was dangerous in cases of appendicitis in children, and operation at the earliest possible stage was advisable; but it must not leave the abdomen in a rough damaged condition. The speaker held strong views about the after-treatment of peritonitis: absolute starvation provided the rest essential for cure, and nothing should be given by the mouth for 48 hours. Ten per cent. glucose and normal saline should be given per rectum every four hours, and continuous intravenous glucose was often of great value. Purgation should be avoided; heat should be applied to the abdomen; and morphia given as long as necessary.

The diagnosis of acute intussusception had often to be made when there were no symptoms of obstruction. The speaker preferred to resect the involved bowel if the child's condition was moderately good, but this was dangerous in children under 1 year of age. The mortality rate for 88 cases was 20 per cent. Intestinal obstruction he described as the most fatal of abdominal emergencies. The diagnosis was often missed as the symptoms are often atypical. Rarer causes of an abdominal emergency were Meckel's diverticulum (26 cases), acute cholecystitis (1), perforated duodenal ulcer (10), and torsion of the ovary.

In the discussion which followed, Miss Gertrude Herzfeld compared the statistics at Great Ormond-street with those at the Royal Edinburgh Hospital for Sick Children. She was surprised to find that the Edinburgh hospital admitted about twice as many acute abdominal cases as were shown in Sir Lancelot's figures; about 1200 having been admitted during the past ten years. The proportion of cases of acute appendicitis is higher, being 72 per cent. in the Edinburgh hospital. In 120 cases of acute intussusception at Edinburgh the fatality-rate was only 8 per cent. Miss Herzfeld avoids resection if possible, and of the 120 cases only 6 were thus treated.

DRESSMAKERS' WARD AT THE MIDDLESEX HOSPITAL. The Bishop of Willesden dedicated, on Nov. 21st, a ward for the use of dressmakers at this hospital. Three beds have already been endowed and a number of firms have undertaken to raise money to endow further beds. It is hoped that in ten years a sum of £25,000 will be raised. It is believed that this is the first ward to be dedicated to a trade.

PANEL AND CONTRACT PRACTICE

THE PANEL CONFERENCE

REPRESENTATIVES of local medical and panel committees held their long deferred annual conference on Dec. 5th in the Great Hall of B.M.A. House with Dr. H. C. JONAS (Barnstaple) again in the chair.

Dr. H. G. DAIN (Birmingham) chairman of the Insurance Acts Committee (I.A.C.), in moving the adoption of the report said it was gratifying to note that as from July 1st, 1935, the remainder of the cut in insurance practitioners' remuneration had been restored. They would now have to consider whether to approach the Government on the amount of the capitation fee. The long and anxious dispute in Llanelli between the workmen's committee and the local practitioners had, he said, been settled with the help of the National Defence Trust funds. He stressed the importance of pushing forward the B.M.A. pensions scheme; insurance practitioners and others had the opportunity during the remainder of the ten-years period agreed with the insurance companies of entering the scheme at the most favourable rates. When these rates were fixed investments were producing about 5 per cent. and it was unlikely that the premiums would ever be so low again.

Representation on the I.A.C.

Since 1917 the direct representatives have been nominated by the local medical and panel committees of each group, and elected by the votes of the individual members of those committees, a practitioner having only one vote in one group even if a member of more than one committee. In 1922 the I.A.C. recommended that only members of panel committees should vote, but this recommendation was referred back. In 1924 the conference asked the committee to inquire into the disproportion which existed in certain areas between the number of voters and the number of names on the medical list, and one area agreed to reduce the number of its committee members. The I.A.C. has now been considering the proposal of a southern group that the voters should be the local medical and panel committee in their corporate capacity and entitled to a number of votes equal to the number of names on the medical list of the area.

Mr. N. E. WATERFIELD (Surrey) moved:—

That this conference requests the I.A.C. to devise a system by which the various groups of practitioners in an electoral area shall have a voting power approximating to the numbers of panel practitioners in the groups; and to arrange for such a scheme to be put into force for the election in 1936.

There would, he thought, be general agreement that voting power should approximate to the membership in an area. The total number of practitioners in Group N. was 2252, while the total membership of the nine panel committees in the group was 258—one vote for each 9.4 practitioners. But in Canterbury a panel committee of 9 represented 10 practitioners, while in Surrey a committee of 36 represented 752 practitioners.

Dr. DAIN said that if the present method of election gave a satisfactory committee there was no need to alter it. Surrey's proposal was more logical, but it would not prevent counties and boroughs supporting each others' candidates. It was time, he felt, for younger practitioners to be given an opportunity of serving on the I.A.C.

Dr. H. R. CRAN (Surrey) did not think the proposal would involve much extra work. The I.A.C. would

decide the value of each vote cast by different committees; this would give the smaller committees a chance of securing representation. It should be made compulsory for the second vote to be used.

The motion was carried by a large majority.

Dr. JOSEPH STARK (Edinburgh) moved:—

That the voting for members of the Insurance Acts Committee should be by members of panel committees.

In Scotland, he said, the I.A. subcommittee was elected by the panel committees and it was felt that the method of appointing direct representatives to the I.A.C. should be similar. He agreed that in some areas the local medical committees included all the practitioners in the area, but the panel committees were more select.

In reply to questions, the CHAIRMAN stated that in three or four areas in England the personnel of the local medical committee differed from that of the panel committee, and that the functions of the local medical committee were restricted to range of service cases and considering disputes between practitioners.

Dr. DAIN regretted that the question had been raised. From the beginning the election of the I.A.C. had been by insurance practitioners with a leavening of non-insurance practitioners. Having been invited to take part in the work of local medical and panel committees it would be uncivil to take from non-insurance practitioners their right of voting.

The motion was lost.

Fitness for Alternative Occupation

Dr. DAIN (I.A.C.) moved:—

That the conference agrees, in cases where an insured person is considered by his doctor to be fit for work but permanently unfit for his former occupation, that the doctor might give an indication to this effect in his next certificate by the insertion in the "remarks" column of the words "alternative employment."

The proposal considered last year was that when a patient was likely to be fit for some employment but was not likely ever or for a long period to be fit to resume his previous occupation, this fact might be communicated to the society in the form of inquiry what action the society proposed to take. This proposal was open to objection as a possible infringement of professional secrecy. When an insured person was permanently incapacitated for his ordinary work and his complete disability was drawing to an end, directly the practitioner indicated that the patient might be fit for some sort of work certain approved societies stopped payment of benefit. Other societies were prepared to act more liberally. The proposal would give a society the opportunity of consulting an insured person about taking up an alternative occupation.

Dr. W. H. BRADLEY (Somerset) in moving as an amendment—

That the conference agrees, in cases where an insured person is considered by his doctor to be fit for work but not fit for his former occupation, that the doctor might refer him to the regional medical officer and indicate his opinion with regard to employment on Form R.M.2,

said that his committee had grave scruples about the motion. An insured person might come to fear that his whole life would be governed by the medical certificate. Even the modified procedure might be felt to violate the rules of professional secrecy.

Dr. R. WARING TAYLOR (Oxon) thought the I.A.C. were asking a remarkable thing. In every certificate,

except the final one, the practitioner certified that the patient was incapable of work: if he was not incapable of work, it could not be indicated on the certificate. It was not the practitioner's duty to suggest the type of employment for which the patient was fit.

Dr. L. V. BROADHEAD (Barnsley) said a man could either work or he could not work and in distressed areas, such as he represented, there was no alternative employment.

After a prolonged discussion in the course of which it was explained by Dr. DAIN that the I.A.C.'s proposal was to deal with the question before the patient was fit for other work, and the feeling was expressed that it was better for the doctor, the patient, and the society to come to an agreement, the amendment was lost by a large majority.

Returning to the motion Dr. DAIN suggested that the additional remark contemplated by the I.A.C. would not contradict the statement on the certificate that the patient was unfit for work. Professional secrecy would be preserved, as in every other certificate, by giving the certificate to the patient. He would object to the endorsement "now fit for light work." Neurosis cases which might be improved by working were not within the ambit of the motion, which related solely to persons permanently incapacitated for their ordinary occupation. He begged the conference to face up to the practitioners' own responsibilities in the matter.

The motion was lost by 54 votes to 87.

Mortgaging of Practices

Dr. T. P. LEIGHTON (Lancashire), presenting a motion asking the I.A.C. to take steps to curtail or stop the exploitation of medical practitioners in connexion with the purchasing and charging of practices, said that the mortgaging of practices had increased lately to an alarming degree. Lancashire felt the gravity of the problem and the need for immediate action. Money-lenders were sending circulars offering to lend up to a hundred per cent. of the purchase price of practices and clerks of insurance committees were receiving letters offering bribes for information as to practices. In Lancashire alone some £40-50,000 a year due to insurance practitioners was assigned to lay people. He knew of one practice which had changed hands four times in seven years, and of two practitioners who had got into the hands of money-lenders and had committed suicide.

Dr. DAIN said the I.A.C. would like to accept an instruction from the conference as suggested by Lancashire, but no practitioner would welcome restrictions on the sale of his own practice. If a man signed a document blindly it was largely his own fault because advice could always be obtained from the Association. The I.A.C. was alive to all Lancashire's points, but while the purchasers of practices should be safeguarded the rights of the vendors must also be protected. It was usually the fact that the new practitioner could not hold the practice that brought about a crash. In his own area (Birmingham) he was informed that there had been no case of default by the purchaser. The I.A.C. hoped to bring forward a scheme of their own for assisting in the purchase of practices.

Dr. J. W. BONE supported Dr. Dain. The point, to his mind, was that if a purchaser is in a position to put down a substantial part of the purchase money or to find adequate security he could readily borrow money from reputable sources. The difficulty was

when he could do neither. Practices were now such valuable assets that the whole of the purchase price could be borrowed and it was a good thing for young men to get into practices of their own if they could make good. Conditions would always be onerous in the absence of security other than the practice itself, and, clearly, in such cases, if the purchaser did not keep up his payments the lender would foreclose. The British Medical Bureau, the Insurance Acts Committee, and the Medical Insurance Agency had set up a tripartite committee which was making strenuous efforts to reach a solution of the problem.

The motion was carried by 61 votes to 42.

Road Accidents

Dr. L. J. PICTON (Cheshire) moved *inter alia* :—

That it is inequitable to deprive panel practitioners who are called upon by the insurance system to give full treatment to accident patients, not on their panel, of the whole of the fees allowed by that system.

That the system now in vogue in Cheshire (under the sanction of the Ministry) by which the emergency fees are allotted as heretofore but diminished (or wiped out) by the deduction of the amount, if any, paid under the Road Traffic Act appears to be equitable.

The I.A.C. might, he said, have been thinking more of the average requirements of urban areas than those in the counties. Cheshire wanted an elastic system which would apply everywhere. He submitted that there were two kinds of emergency treatment: (1) that required at the time and place of the accident; (2) other within the next 24 hours, perhaps in a cottage hospital. First-aid at the scene of the accident followed by the toilet of a compound fracture should, he felt, attract a fee of more than 12s. 6d.

Dr. DAIN pointed out that the fees for emergency treatment were a matter for settlement between the panel committee and the insurance committee in the areal distribution scheme. Cheshire had already made an arrangement which they regarded as suitable, but this was purely domestic. There was nothing to prevent any other area taking action similar to Cheshire. Books of claim forms could be obtained containing statements of the legal position and it was most desirable that panel committees should see that their constituents had these books.

It was agreed that the points raised by Cheshire should be referred to the I.A.C.

Medical Records

The I.A.C. had given its approval to a new regulation providing for the investigation of alleged failure to keep proper medical records of insured persons. Kent's motion—

That the conference instructs the I.A.C. to press for the abolition of the compulsory statistical compilation of national health insurance medical records and to secure that these medical records be used primarily for such clinical notes as are of real value

led to an animated discussion. Dr. B. H. PAIX thought that definite steps should be taken to alter the bias of the Ministry from the statistical to the clinical side when assessing the value of a practitioner's records. There was no need for compulsory statistics; Scotland and Northern Ireland had abolished the requirement to note all attendances and visits. In reply to a question by Dr. H. J. CARDALE (London) it was however pointed out that the forms of record in Scotland differ much from those in use in England and Wales.

Dr. DAIN stated that the conference had always hitherto decided to retain the medical records in their present form. Scottish doctors had to coöperate in organised research in place of entering ticks; there was no throwing off the shackles. The entry of a tick on a record card ensured that the doctor had the record in front of him in order to make the tick. He gathered, however, that R.M.O.'s are now instructed to pay more heed to the clinical notes and less to the numbers of ticks.

The motion was lost.

Immunisation against Diphtheria

An amendment by Middlesbrough was withdrawn in favour of a London amendment moved by Dr. A. K. GIBSON in the following terms:

That this conference is of opinion that the responsibility of insurance practitioners in regard to diphtheria immunisation should be confined to immunising patients who bring a certificate showing that they are Schick positive.

London generally agreed, he said, that insurance practitioners should take their share in new forms of treatment. Immunising as such was simple, but Schick testing could not always be done thoroughly by general practitioners. There were schemes in London boroughs covering children from the age of 1 to 12 years. After 5 years of age a child was more exposed to infection and usually either got diphtheria or acquired an immunity to it, which gradually increased up to 12 years of age and even beyond. Experts said that unless they could themselves Schick test children between 1 and 5 years old they could not be absolutely certain about the potency of the toxin they were using. The difficulty was not in the application but in reading the results. If an insurance practitioner got a negative result and, as was very often the case, had no chance of testing the potency of the material, he might be led astray.

Dr. DAIN thought the London amendment would lead to an interesting part of insurance practitioners' work being handed over to the public health authorities. He could not think that insurance practitioners as a class were less fit than (say) a junior medical officer of a public health department to apply the test. In these days the material used was unlikely to be impotent.

Dr. C. W. SOMERVILLE (Midlothian) raised the question of the cost to the drug fund. If one child was done at a time, three separate capsules were required; whereas he was frequently able to immunise twenty or thirty at a time when the cost per head was much lower.

Dr. A. J. LEWIS (Southport) asked whether the patient was to be tested and immunised at his own desire. Dr. Dain's reply was that the service would be rendered at the request of the patient but at the practitioner's discretion.

The London amendment was lost by 63 votes to 66.

The Defence Trust

Mr. N. BISHOP HARMAN reported on the present position of the National Insurance Defence Trust; the excess of income over expenditure for the past year was, he said, some £12,000; rise in the price of gilt-edged securities added some £48,000 to the capital value of the fund, which now stood at over £280,000. Dr. DAIN reminded the conference of certain financial responsibilities undertaken in respect of the Llanelly dispute which did not appear in the statement of accounts. Dr. OSCAR WILLIAMS (Carmarthenshire) expressed the appreciation of Llanelly

practitioners for what had been done for them; it was gratifying to find that the Association had weapons which the local practitioners had not realised. He hoped that the experience gained in that dispute would lead to the easier settlement of other disputes. Dr. Dain said that, at the instance of the Llanelly practitioners, the Carmarthen area had subscribed a further 250 guineas to the Trust Fund, although they had reached their quota in 1932.

Dr. J. A. BROWN (Birmingham) moved to authorise the trustees to raise a defence loan from insurance practitioners to supplement the present funds of the trust. The idea of a loan instead of a donation would, he thought, appeal to many practitioners, and it could be based either on equal contributions from each practitioner or on a sliding scale according to the size of his panel. It should be returnable on death or withdrawal from insurance practice and the loan should not be utilised unless and until the existing trust fund had been exhausted. The proposal was referred to the trustees.

Dr. M. W. RENTON moved on behalf of Kent to make one of the objects of the trust the financial support of selected medical candidates for election on public health authorities where it is deemed necessary in the public interest. There was a danger lest lay authorities without medical members to present the medical point of view should make only whole-time medical appointments in their services. In Kent the profession had been refused access to the public health authorities and their only alternative was medical representation on those authorities. This proposal also was referred to the trustees.

Remuneration

Dr. A. BEAUCHAMP (Birmingham) wished the I.A.C. to approach the Ministry and ask for an adequate capitation fee. Since 1924 the capitation fee had remained at 9s.; insurance practitioners in 1935 were doing more work than was anticipated in 1924, both in treatment and in diagnosis. They should give the best possible service but the capitation fee should be commensurate with their obligations.

Dr. A. BALDIE (London) thought that even if this was not the time to press for reconsideration there was work to be done in preparation for negotiations. At present insurance practices of less than 800 patients were not an economic proposition. Numerical statistics were fallacious; insurance practitioners should show how their work was done, so that this information might be submitted to the Ministry when the time came.

Dr. DAIN said that ever since the last award the I.A.C. had been preparing for the next. It would be better, he thought, to wait until they could appear before arbitrators and show how each criticism of the service had been met and the necessary adjustments made. It would be simple to show how the work had increased in volume and intensity; he need only mention the treatment of varicose veins and the Schick test. The award was open to be challenged at any time by either side, but hitherto neither side had challenged it and he was not sure that immediate action would be prudent.

Dr. BEAUCHAMP reiterated his opinion that the time for reconsideration was ripe, but the conference decided (with one dissentient) to proceed to the next business.

Sundry Resolutions

Dr. T. D. LAIRD (Lanark) asked for a ruling that the medical treatment provisions of the National Health Insurance Act ought to be extended to include

all persons of a like economic status to the insured, and the conference agreed.

Dr. R. WALKER (Cardiff) asked for an expression of opinion that all insured persons should be entitled to dental benefit. It was anomalous, he said, that members of some approved societies could get much help with the cost of dental treatment and others could obtain none. In Sweden dental treatment was

provided from three years of age onwards, but at home the dental condition of many of their patients was deplorable. The motion was carried.

A vote of thanks was accorded to Dr. Jonas for his services as chairman of the conference and to Dr. Dain, chairman of the I.A.C. Mr. D. Elliott Dickson, F.R.C.S., of Lochgelly (Fife), was appointed chairman of next year's conference.

PUBLIC HEALTH

Doctor and Midwife

At its council meeting on Nov. 20th the British Medical Association had before it two memoranda drawn up by its National Maternity Service Committee.

NATIONAL MATERNITY SERVICE

The first of these, after reviewing the recent trend of maternal mortality and noting the fact that, in spite of the steadily growing provision of antenatal clinics and hospital accommodation, the number of deaths from eclampsia were still rising, emphasised the principle of continuity of medical and nursing care throughout pregnancy, labour, and the puerperium as the basis of any successful scheme. It had been suggested in some quarters that a State-aided rate-aided service should be conducted by obstetric specialists. The answer to that suggestion was that the incident of pregnancy should not be the signal for the transference of the woman from the care of one practitioner to another. Maternal mortality was not attributable to one clearly defined factor which would be absent from a special service of the kind suggested. The birth of a child was not a mere mechanical event unrelated to the life history of the mother; and a specialist in sole charge of the patient who was without full personal knowledge of her medical history would be imperfectly equipped for her care during pregnancy, labour, and the puerperium. The B.M.A. Council is of opinion that the most frequently needed forms of intervention in childbirth do not require more skill than has been attained by the vast majority of general practitioners, or than can be achieved by medical students during the extended period of training now laid down by the G.M.C. It is rather the judgment to decide when to intervene or whether to intervene at all that is required for good midwifery practice. To secure the required continuity of care the B.M.A. Council would insist on the provision of a general practitioner and a certified midwife for every maternity case. The reform of the practice of midwives would not in itself remedy the present chaotic system. The scheme is set out in brief as follows:—

- (1) Efficient antenatal care by, or under the responsibility of, a medical practitioner throughout pregnancy in every case.
- (2) Attendance in every case by a certified midwife during the antenatal period, labour, and the puerperal period.
- (3) Attendance by the practitioner chosen by the patient during pregnancy, labour, and the puerperal period, when, as a result of his antenatal examination, the practitioner has declared his personal attendance to be necessary, or when his attendance is requested by the midwife.
- (4) The provision in every case of at least one post-natal consultation between the patient and the practitioner (including, if necessary, examination).
- (5) The services when necessary of a second practitioner (for example, to administer anaesthetic).

(6) The services of a consultant when considered necessary by the practitioner.

(7) The provision of laboratory services when considered necessary by the practitioner.

(8) The provision of beds for such cases as in the opinion of the practitioner require institutional treatment; treatment in the institution being, as far as possible, continued by the same practitioner.

(9) Supply of sterilised obstetric dressings in every case.

(10) Provision of ambulance facilities for patients requiring to be removed to institutions.

(11) The provision of "home helps" (i.e., women trained in domestic work), who would relieve the mother of the worries of domestic management during the lying-in period.

The best method of providing a maternity service of this kind would, in the B.M.A. Council's belief, be an extended system of National Health Insurance.

WHOLE-TIME SERVICE OF MIDWIVES

The B.M.A. Council also had before it a memorandum on the report of the Joint Council of Midwifery. It was agreed that if a whole-time service of midwives was to be adopted in certain areas, that was more a matter for the midwives themselves than for the medical profession, provided that if there was to be such a service, the following conditions must be regarded as essential:—

- (1) That there should be as free a choice as possible of midwife by patient.
- (2) That in the case of individual midwives, skill, judgment, and personality should reap their reward.
- (3) That the medical practitioner should have the opportunity of advising his patient as to the midwife who will undertake in association with him the responsibility for that patient's welfare.

Ozone for Water Purification

It is remarkable that ozone, which about 50 years ago was popularly considered to be the most beneficial constituent of sea air, has been little used in this country for the purification of water although on the continent and more especially in France it is frequently used in preference to chlorine or chloramine. Lieut.-Colonel G. Ewart Morgans, of the "Otto" Company, in a paper read at the recent Public Works, Roads and Transport Congress, makes a strong case for ozone as a means of purifying water both for domestic use and for swimming baths. Ozone, it seems, acts entirely by virtue of its oxidising power; hence when it is desired to sterilise water by its means the water should contain little organic matter other than the organisms it is desired to kill. Colonel Morgans suggests not more than three milligrammes of oxidisable organic matter per litre, a degree of purity which in many cases must be reached by sedimentation or filtration. This is perhaps not altogether a disadvantage as it is surely desirable that permanent water-supplies, as distinguished from the water for an army in the field, should not only be sterile but be in every way acceptable to the consumer—a condition which for many sources of public

supply can best be attained by storage, followed if necessary by filtration. Whatever sterilising agent is used will of course be most effective when the water is clear and organically pure; this is essential for treatment by ultra-violet light or catadyn silver, and advisable for ozone if it is to be used at a reasonable cost. The outstanding advantages of ozone are: (1) it yields a fine colourless table water in a very short time, and (2) if excess is removed it leaves no taste or odour whatsoever. The water is then

sterile but is left with no bactericidal action; on the other hand any residual ozone may attack the metal pipes through which it is to be distributed. Whilst the sterilising action of ozone is much more rapid than that of chloramine there seems to be some doubt whether it is as effective against the leptospira of Weil's disease which, from its association with rats, is likely to be present in water which has been contaminated with sewage or to which rats can gain access.

CORRESPONDENCE

REGULATION OF PROSTITUTION

To the Editor of THE LANCET

SIR,—The report of the recent Congress of Dermatology at Budapest (THE LANCET, Nov. 9th, p. 1078) and your leading article on it in the issue of Nov. 30th will interest many who consider the socio-political aspects of medicine. At that congress, which was called international, "It was accepted as a fact that syphilis and gonorrhoea could be made extinct throughout the world within a single year if all who suffer from them would have themselves fully treated. Starting from this principle the Congress proposed the application of legal penalties and State control of treatment, together with the regulation of prostitution." (My italics.) I wonder how many nations had representatives there. What "legal penalties" may mean, I do not know; it probably means penalties for not reporting for cure, and/or for transmission of disease. The first assumes capacity for self-diagnosis; the second implies denunciation of the supposed donor.

Regulation means the licensing of prostitutes, either in brothels or otherwise, to practise their "calling," with enforcement of medical examination at short intervals for detection of disease. Here, as well as in Scandinavian countries and elsewhere, this method has been discarded. France stands at the head of European countries which still regulate prostitution. Germany abolished the system in 1927, but seems to have reverted to it. And I am informed that in other countries there is a tendency to gravitate back to that useless and offensive system.

What are the facts? It is, I believe, undeniable that venereal disease is more prevalent where regulation is in force than where it is not. And the reasons are plain enough. Brothels are a standing temptation to young men, who understand that the government regards them as a necessary evil (if not a necessary good). The examination of the women is a perfunctory procedure, taking a minute or two to each person, which cannot guarantee freedom from disease, and is more likely (through instruments) to transfer disease from one woman to the next. Apart from that, women do not like being dragooned and harassed; so in any great town the "clandestines" are generally about ten times as numerous as the licensed; so that the examination, even if efficient, would only touch a fraction of the prostitutes. Regulation, in fact, is not only a failure from the side of public health, but is a stimulant to debauchery, and, incidentally, is the prime factor in the promotion of the traffic in women.

It is said that if you abolish regulation where it exists and close the *maisons tolérées*, turning the women on to the streets, there will be an increase of disease. This might be so (though not necessarily) if no steps are taken to give due notice of the proposed closure

and to find some means of livelihood for the brothel inmates. But in fact the abolition of regulation has not so resulted where it has been properly tried. There must always be some difficulty attending the abolition of a great evil. The conditions of life in the brothels are revolting; the licensed women are under the control of the *police des mœurs*; blackmail and every kind of abuse is lamentably common; brothels, with their enormous profits to the tenanciers, are a source of corruption in public life.

Am I then advocating free prostitution as a preferable alternative to the regulation system? Yes; so long as there is no persistent molestation in the streets, by either sex, nor public indecency. Prostitution is not a crime in law, and ought not to be under any legal restrictions that are not applicable to all. Free prostitution is better than regulated, whether for public health or public morals. In this country, for better-thinking people of all classes, prostitution (so different from mid-Victorian days) is becoming obsolescent as being beneath human dignity. Its place is being taken, no doubt, by temporary liaisons of a more or less affectional character. That is not ideal; but, at any rate, it is a step in advance from crude promiscuity. Social habits improve slowly.

As to Budapest, no congress can be representative of international thought which seeks to adopt methods which have already been rejected, with advantage, by the most progressive countries in the world.

I am, Sir, yours faithfully,

Harrow, Dec. 3rd.

DOUGLAS WHITE.

COLLAPSE THERAPY IN PLEUROPNEUMONIA

To the Editor of THE LANCET

SIR,—Having used artificial pneumothorax in the treatment of 45 cases of acute lobar pneumonia, and several cases of acute pleurisy without definite pneumonia, I venture to make some comments on the interesting articles by Dr. Cedric Shaw and Dr. W. E. Robertson in your issue of Dec. 7th. I have obtained results as dramatic as those described by Dr. Shaw in the relief of pleural pain, but as the relief does not occur in every case I cannot agree with him that "there remains the universally accepted clinical observation that separation of the visceral and parietal pleural layers, whether by fluid or by air, results, without exception, in the disappearance of the pain of acute pleurisy."

It is commonly taught and generally believed that the pain of acute dry pleurisy is due to the rubbing together of inflamed pleural surfaces. There are many reasons, as Bray¹ has pointed out, for thinking that another mechanism exists—namely, pleural tension. For example, typical pleural pain may occur in a patient with a pneumothorax and a completely collapsed lung without pleural adhesions when the

¹ Bray, H. A.: Amer. Rev. Tuberc., 1926, xlii, 1.

friction element is obviously absent. This pain may cease when effusion occurs, just as it does in cases with pleural friction. On the other hand, patients are sometimes seen with loud and palpable, but painless, basal pleural friction. I note that Dr. Shaw gave a refill when a faint pleural rub reappeared in both his cases, but he does not say whether pain accompanied this rub. I have observed that when pleural pain recurred after artificial pneumothorax (600 c.cm.), X ray examination sometimes showed that the pleural surfaces were still separated. I should mention that in all my cases the presence of pneumothorax has been confirmed by X ray examination taken, when possible, in full expiration. Dr. Shaw himself says that neither the theory of pleural friction nor of pleural tension is universally applicable. It is then perhaps unwise to claim that a measure which may eliminate one of these factors only will invariably relieve pleural pain. The problem is not merely that of separating pleural surfaces.

About the treatment of pneumonia it is difficult to dogmatise, especially when the type of the causal organism is not specified. Many writers—e.g., Coghlan²—have based their claims for the efficacy of pneumothorax in lobar pneumonia on small numbers of cases. Dr. Robertson's series is, I believe, the largest. I am reluctant to draw definite conclusions from my 45 cases (about half of which were not typed), but I would agree that pneumothorax does not appear to have any influence, favourable or otherwise, on the outcome of acute lobar pneumonia, although it may relieve pleural pain in some cases. Incidentally, the credit for first suggesting the employment of artificial pneumothorax belongs to James Carson of Liverpool.³ Typical cases of lobar pneumonia with definite clinical and radiological signs can end by crisis within five days of the onset. Pneumothorax given to such cases might be credited with the cure. I feel that some of the enthusiastic statements of the advantages of pneumothorax lack the restraint which a fuller knowledge of the natural history of the disease would bring.

The proviso with which your annotation wisely concludes, that artificial pneumothorax "should only be adopted if pleural pain and respiratory distress aggravate incipient disease," precludes pneumothorax treatment in many cases, particularly those of the hospital class, since they are well past the incipient stage when first seen.

I am, Sir, yours faithfully,

C. ALLAN BIRCH.

London, N., Dec. 9th.

PHILOSOPHY AND AFFAIRS

To the Editor of THE LANCET

SIR,—You were kind enough four years ago to publish a letter appealing for support of the British Institute of Philosophy, which was founded in 1925 with the late Lord Balfour as its first president. The appeal was based on the existing disorganisation of beliefs in fundamental principles in every department of life, and the need of a cultivation of systematic thought that has the most intimate bearing on practice. Since then this need has not diminished. We have seen in the interval the rise of forms of political life which appear to deny those constructive forces which have been generally regarded as of first importance. On this and on other accounts we need to consider what the primary and wrong in the conduct of nations should be.

We therefore in the tenth year of the Institute venture to ask again for your hospitality with a view to making its work better known and obtaining further support that will enable it to extend its activities. These consist at present of the publication of the quarterly review *Philosophy*, the holding of courses of public lectures, the organisation in London and other cities of reading circles, and the arrangement of monthly evening addresses by leaders of opinion in various departments of thought—scientific, æsthetic, political, moral, and religious. Those of your readers who would desire to become members of the Institute (the subscription is £1 1s., which covers the price of the quarterly review) or to obtain further information with regard to it are invited to communicate with the Director of Studies at the rooms of the Institute in University Hall, 14, Gordon-square, London, W.C.1.

We are, Sir, yours faithfully,

S. ALEXANDER,

COD-LIVER OIL TREATMENT OF BURNS

To the Editor of THE LANCET

SIR,—Since reading Dr. J. P. Steel's account, in your issue of August 10th (p. 290), of his successful treatment of severe burns with cod-liver oil I have used the oil in several cases of severe burns of the eyelids and in one case of a very bad burn of the eyeball with caustic liquid. The first (and worst) case was brought in while I was reading his article. All these cases, really bad ones, have healed in the most remarkable way. The worst of them was back at work again in about a month, and none of them shows any signs of scarring, symblepharon, or discoloration of skin—in fact no sign of having been injured, except that of loss of eyelashes where the lid margins were burnt through. No other treatment was used except the wiping away of mucous discharge, and an occasional drop of atropine. Shortly after my first case I tried the oil as a sort of last resource on the left eye of a child, aged 4, who had been under continual treatment for about 12 months for an unusual chronic ulceration of the cornea accompanied with much pain, œdema of the lids, and photophobia. Drops of oil were instilled every three hours and the result was surprising; after the first day the child opened the eye for the first time for many months, and the whole cornea was healed up in four days.

Since then I have tried cod-liver oil in various corneal conditions and have had excellent results in dendritic ulcer, in which pain is relieved at once and very rapid healing takes place with no other treatment except the oil drops every three or four hours. Chronic keratitis, small ulcers caused by foreign bodies, phlyctenular conditions, and corneal roughness and superficial ulceration of trachoma are also suitable for the treatment. I tried it in one case of hypopyon ulcer, but this was such a severe infection that it was impossible to omit other more drastic remedies, so that the ultimate good result cannot be claimed entirely for the use of the oil.

Application of the treatment is very simple. For burns of the lids the first dressing is a pad of lint saturated with the oil, covered with jaconette or oiled silk and a bandage, the patient being instructed to get a bottle of the oil and to keep the pad moist.

² Coghlan, J. J.: *THE LANCET*, 1932, I., 13.

³ *Essays, Physiological and Practical*, Liverpool, 1822.

with it, leaving the pad undisturbed for 24 hours. There is never any septic discharge. The pad is changed every 24 hours. For use as drops: at home the easiest way is to pour the oil from a warmed teaspoon, rather than use a dropper which is difficult to keep clean, every three or four hours. One remarkable point is the almost instant relief from pain.

I hope that others will try this treatment, for even if unsuccessful it has the advantage of being harmless.

I am, Sir, yours faithfully,

Liverpool, Dec. 9th.

EDGAR STEVENSON.

FEVER HOSPITALS

To the Editor of THE LANCET

SIR,—In the annotation headed Fever Hospitals. Past and Future, which appears in your issue of Dec. 7th (p. 1308), there is a statement against which I desire to protest, to wit: "The bed-spacing which is now the rule would even thirty years ago have seemed fantastically extravagant or divinely fortuitous." Forty years ago the medical superintendents of the fever hospitals of the Metropolitan Asylums Board recognised and insisted upon the necessity of as ample floor-space in the wards as is provided at the present time. As you were kind enough on a previous occasion to publish a letter from me on this subject (see THE LANCET, 1933, ii., 1448) I will not now trespass further on your space, except to say that I had the pleasure of listening to Dr. Harries's admirable address and to the best of my recollection he did not use the words I have quoted.

I am, Sir, yours faithfully,

Hampstead, Dec. 9th.

E. W. GOODALL.

* * Dr. Harries was referring not to bed spacing in the open ward but to the recent provision of ample isolation accommodation and we regret the false impression given in our necessarily brief note. The words "divinely fortuitous" were not his. We take this opportunity of amending other statements in the annotation. After remarking that the decline in the fatality-rate from diphtheria had reached the limit, Dr. Harries added that the disease is now preventable. Dr. Harries did not say that instruction in fevers is at present quite inadequate. What he did say was that knowledge of clinical work of fever hospitals was based upon a limited number of attendances at a fever course which provided no opportunity for day-to-day observation of the patients. The phrase quoted in the annotation about the "apparatus and protocols of a scientific paper" was used specifically in relation to the unsatisfactory literature of the vaccine therapy of whooping-cough.

—Ed. L.

BOTULISM

To the Editor of THE LANCET

SIR,—In your issue of Sept. 28th, in collaboration with Dr. Jones-Davies, I reported a case of botulism. May I be permitted to add a few further details which have since been worked out?

Since our report the organism from the nut brawn has been isolated in pure state and a toxin prepared from it in a similar manner to that which was prepared from the impure culture; this pure toxin killed a guinea-pig within 24 hours in a dose of 0.001 c.cm. Through the kindness of Mr. Dalling, of the Wellcome Physiological Research Laboratories, Beckenham, I was able to obtain monovalent botulism antitoxic sera of the three types A, B, and C. Protection experiments on guinea-pigs gave the following results.

One cubic centimetre of type A antitoxin protected against 0.001, 0.01, and 0.1 c.cm. of the pure toxin but not against 1.0 c.cm. One cubic centimetre

of both type B and type C antitoxin failed to protect against 0.001, 0.01, 0.1, and 1.0 c.cm. of pure toxin, though in the case of the smallest dose of toxin life was prolonged to six days by type B antitoxin and to 19 days by type C antitoxin. The organism is thus a clear-cut type A. The pure strain of the organism fermented with gas production: lactose, glucose, dextrose, and salicin. Fermentation of the last-named is said to be distinctive of type A strains. In glucose agar, however, the deep colonies were not of the compact, discoid nature said to occur with type A, but rather woolly like B or C strains.

The finding of type A in this case is of interest in view of the fact that while the Loch Maree outbreak was due to a type A. Meyer and Dubowsky in their report, in the *Journal of Infectious Diseases* (1922), on an examination of soils and vegetables found type B present, but type A consistently absent in Europe.—I am, Sir, yours faithfully,

Wimpole-street, W., Dec. 3rd. C. RICKWORD LANE.

A TEST FOR CANCER

To the Editor of THE LANCET

SIR,—A few years ago Dr. J. Round designed a test for cancer on Bendien's lines by the use of urine instead of blood. Dr. Round worked with a chemist, Mr. D. A. Ruddle. Dr. Round as director and Mr. Ruddle as chemist for tests and research are now working at a laboratory at No. 12, Park-crescent, W.1. The findings here on cancer urines and suspected cases have been proved to be satisfactory clinically by a number of medical men and have usually confirmed other tests. It is often found preferable to use urine as any one can take a specimen of early morning urine. The patient also prefers this method to having blood taken from a vein.

The undersigned can speak from personal experience of the advantages of the test, not only can malignancy be judged by flocculations at a certain degree of pH, but by the presence of other substances. Further, if the presence of malignancy is not indicated further tests can be made to aid diagnosis. In doubtful cases an additional test can be made from faeces, as in malignancy the amount of zinc in faeces is decreased. Practitioners desiring to use the services of the laboratory should send 4 oz. of urine with a little chloroform added to Mr. D. A. Ruddle, 12, Park-crescent, W.1. Fee £1 1s. Research on the nature of cancer has been carried out and this could be extended if funds were available. The support of the profession is requested for what may lead to still more useful research.

Those desiring further information should address Dr. J. Round, 67, New Cross-road, London, S.E. 14.

We are, Sir, yours faithfully,

GEORGE BURFORD, JNO. ROUND,
R. M. LE HUNTE COOPER, C. E. WHEELER,
W. GUYON RICHARDS, H. WYNNE THOMAS.

London, Dec. 6th.

"A CURIOUS EPIDEMIC OF SORE-THROAT"

To the Editor of THE LANCET

SIR,—I have been using in my practice diphtheria antitoxin (P. D. and Co.) in cases of severe tonsillitis and sore-throat with very gratifying results. The temperature generally falls to normal after two injections; the patient feels more comfortable. I think that in the presence of slight throat signs and mild temperature, quite apart from the presence of diphtheroid bacilli, antitoxin will prove valuable.

I am, Sir, yours faithfully,

S. R. BHAT, M.B., B.S.

Amraoti (C.P.), India, Nov. 15th.

HÆMOPHILIA AND INFANTILE MORTALITY

To the Editor of THE LANCET

SIR,—In your last issue (p. 1289) Dr. W. M. Priest describes a case of hæmorrhage within the central nervous system in a case of hæmophilia, a somewhat exceptional occurrence. In his case the family history was negative, or rather was unobtainable owing to the ignorance of the patient's mother as to essential facts. Dr. Priest was however able to note that the patient had 12 brothers "five of whom died in infancy but there was nothing to suggest hæmophilia as a cause of death." That is to say, out of 13 male infants 5 had not survived infancy, a mortality of over 38 per cent. Such a death-rate in male infants in a hæmophilic stock is full of significance. It has already been noticed and commented on in an article of mine entitled "A Pedigree of Hæmophilia" (Brit. Jour. Child. Dis., 1932, xxix., 276) from which with your permission I will take the following extract:—

"Out of 66 persons, some 14 died in infancy or early childhood (excluding the hæmophilic disasters, which would make these figures even greater), as often as not the cause of death being described as convulsions. If the obvious cases of hæmophilia are excluded from both sides of the calculation the figures are even more striking, the wastage of child life being 14 out of 59 individuals, or nearly 24 per cent., in children born throughout three generations in different environmental conditions in two different counties. Of the fatal cases of convulsions, 5 out of 7 occurred in male children, and it seems possible that some, at least, of these children dying convulsed may themselves have been cases of hæmophilia, dying in this way before the familial stigma had obtained any opportunities to show itself in any of its orthodox manifestations. It seems reasonable to suggest the possibility that some of them may have had an intracranial hæmorrhage, irritating the brain substance, and so leading directly to the convulsions which proved fatal. Perhaps, indeed, every case of convulsions in a male infant in a hæmophilic family should be considered as suspect from this point of view."

From Dr. Priest's figures, where out of 13 male children 5 died in infancy and 1 grew up with hæmophilia, it may be surmised that his case is not so much one where his patient was the subject of sporadic hæmophilia, as one where the mother was the carrier of the taint which she transmitted to 6 out of 13 (or 46 per cent.) of her male offspring, a percentage which accords with expectation.

I am, Sir, yours faithfully,

Manchester, Dec. 7th.

W. J. RUTHERFURD.

EXPLOSION IN OPERATING THEATRES

To the Editor of THE LANCET

SIR,—In connexion with the letter from Sir Joseph Petavel your readers may be interested to learn that the subject has for some time past received attention from the Anæsthetics Committee appointed jointly by the Medical Research Council and the Royal Society of Medicine. This committee has had the benefit of coöperation with the National Physical Laboratory as regards the electric causation of the explosions. The committee has been able, largely owing to the investigations carried out for it by the late Prof. H. B. Dixon, to point out to anæsthetists dangers which had not hitherto been apparent, particularly in connexion with the mixture of nitrous oxide with other vapours. As regards the determining cause of the explosion of an anæsthetic mixture in practice this appears to arise in one of two ways, either from electrification of the table, &c., or from faulty electrical apparatus, small lamps, suction

machines, and so on. The anæsthetist has learned which of his agents to avoid in the presence of open flame, cautery, diathermy, &c. In the absence of these things he naturally expects to work without the risk of getting an electric shock or having his apparatus blown to smithereens, whatever anæsthetic he chooses to employ. We may hope that the efforts of the National Physical Laboratory will result in this assured liberty.

I am, Sir, yours faithfully,

J. BLOMFIELD,

Dec. 9th.

Chairman, Anæsthetics Committee.

TREATMENT OF HÆMATEMESIS

To the Editor of THE LANCET

SIR,—I was much interested in Prof. Meulengracht's paper in your issue of Nov. 30th, as the basis of his treatment of hæmatemesis corresponds fundamentally to my own. Although I think that during the actual time when hæmatemesis takes place no food at all should be given because the stomach secretions diminish considerably during starvation, I agree that no notice need be taken in respect of melena. I am prepared also to accept that "light" food is permissible during hæmatemesis, as it must remain, for the time being, a difficult point to decide whether food in the stomach interferes with the arrest of the hæmorrhage, and I should not be surprised that the presence of solid or semi-solid food has rather the opposite and desirable effect. As the period of practical starvation is only a relatively short one and should not exceed 48 hours, Prof. Meulengracht will agree that there cannot be a very great loss of energy due to lack of food. However, when it comes to the point when food has to be administered, I am afraid I cannot agree with Prof. Meulengracht's diet. As soon as I am satisfied that the hæmorrhage has been arrested, I have no hesitation in putting the patient on a fat-free régime, and up till now I have had no reason to regret my action. In any case, one need not hesitate to administer glucose ad lib. from the very commencement of treatment.

A point of the utmost importance which I should like to emphasise is the paramount necessity of distinguishing acute from chronic ulcer, as both prognosis and treatment must necessarily depend on their differentiation. The correspondence which followed Mr. Gordon-Taylor's recent contribution in your columns, if it did nothing else, illustrated the need to distinguish between the acute and chronic ulcer in reporting results. It would then be realised that a general and different method should be applied to the treatment of cases of acute ulcer which, as I have attempted to show, behaves in every respect as an experimental ulcer, and is either toxic or infective, or, at any rate, systemic in origin. As far as the chronic ulcer is concerned, which is due to active local mischief, these are the only cases where sometimes the physician may require the help of the surgeon. Prognosis will always be influenced by the general condition of the arteries and must therefore be taken into consideration.

Finally, may I draw your attention to the fact that sometimes one comes across cases of hæmorrhage from acute ulcers in patients who have had a long history of dyspepsia with a cured chronic ulcer. I have seen several of these and found it most difficult to convince the doctor in attendance that the hæmorrhage was not due to the old chronic ulcer, but caused entirely by a new condition independent from and superimposed on the old one.

I am, Sir, yours faithfully,

Bolton-street, W., Dec. 7th.

J. JACQUES SPIRA.

THE MAURICE CRAIG MEMORIAL

WE have received from the hon. treasurer of the Sir Maurice Craig memorial fund the following letter:—

"When Sir Maurice Craig, the distinguished psychiatrist, died in January last, it was felt by his friends and colleagues that there should be some memorial of one who was a pioneer in the treatment of nervous and mental illnesses, and who contributed such invaluable knowledge to their early diagnosis and prevention.

"Sir Maurice was a great mental specialist, and with his name must be associated the importance now attached to rest and sleep in cases of nerve exhaustion, the use of small doses of a sedative over a long period, and to the toxic focus as a cause of certain severe mental disorders. He never failed to attach the correct value to the physical condition of his patients, and knew the relative value of the smallest symptoms. His whole life was one of consistent personal service, and his name will be linked with the prevention, and progress in treatment, of mental and nervous diseases. He was never happier than in 'opening up the lives' of young people who in one way or another were being repressed or thwarted, or when highly-strung children were brought to him and he was able to protect their nervous systems against the effects of strains and stresses. His power of throwing the whole of himself into the particular troubles of the individual, which gave him his wonderfully understanding and strengthening sympathy, combined with his charm, were invaluable assets in gaining the confidence and affection of patients.

"Sir Maurice Craig's greatest public work in the field of mental health was in two directions: his part in establishing the National Council for Mental Hygiene, and in the foundation (with the funds generously placed at his disposal by Sir Ernest Cassel) of the Cassel Hospital for functional nervous disorders. Remarkable evidence of Sir Maurice's hold upon the public was seen a few years ago when he made a broadcast appeal on behalf of the National Council. This appeal produced an overwhelming number of letters from listeners in all parts of the country and from all sections of the community, notably among the poorer classes, who emphasised their appreciation of the work done for the mental health of the nation by Sir Maurice and the Council over which he presided.

"The friends of Sir Maurice Craig therefore feel that it would be in keeping with his wishes that sums received for the memorial should be entrusted to the National Council for Mental Hygiene for the furtherance of the work which he had so much at heart, and to found a 'Maurice Craig House' which would become the established centre of the National Council. Such a centre should greatly assist in co-ordinating the work of all voluntary bodies dealing with mental health and the prevention of nervous and mental disorders, and provide, for instance, much-needed meeting rooms for the National Council's various research committees, a library, and an inquiry department to supply the public with particulars concerning treatment facilities, training in all branches of mental health, information, and literature. It is proposed that as a beginning some temporary premises shall be taken with the object of establishing a permanent 'Maurice Craig House' when sufficient funds have accumulated.

"We feel sure that in addition to his professional colleagues, friends, and patients, there must be many among the general public who would wish to co-operate with us in giving permanence to Sir Maurice's work for the alleviation of human suffering, and that in a manner which would do honour to his memory. Contributions to the fund, which should be marked 'Sir Maurice Craig Memorial Fund,' will be gratefully acknowledged by Dr. Eric Wornum, 121, Harley-street, London, W.1, who has consented to act as hon. treasurer."

The letter is signed by the Archbishop of Canterbury.

Lord Wakefield of Hythe, Lord Southborough, General Sir Walter Braithwaite, Sir Reginald Ward Poole, Dr. A. Helen Boyle, Sir Farquhar Buzzard, Lady Limerick, and the Bishop of Chichester.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. A. C. Paterson to *Pembroke* for R.N.B.
Surg. Lt.-Comdrs. J. M. Sloane to *Fernon*, E. E. Malone to *Excellent*, and G. Phillips to *Boscawen*.
Surg. Lts. C. N. H. Joynt and W. J. M. Sadler to be Surg. Lt.-Comdrs.

ROYAL ARMY MEDICAL CORPS

MILITIA

Maj. F. G. Foster retires on attaining the age limit and retains the rank of Maj.

TERRITORIAL ARMY

Capt. F. McL. Richardson to be Div. Adj., 51st (Highland) Div., vice Capt. S. R. M. Mackay, vacated.

Supernumerary for service with O.T.C.—Maj. H. P. Malcolm, M.C. (empld. Queens Univ. (Belfast) Contgt. (Med. Unit), Sen. Div., O.T.C.), resigns his commn, and retains his rank, with permission to wear the prescribed uniform.

Lt. G. Green to be Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS

Lt. C. A. Cromar, from T.A. Res. of Off. (4th Bn. Gordons), to be Lt.

Lt. A. S. Gough resigns his commn.

ROYAL AIR FORCE

Squadron Leader H. Penman to Central Medical Establishment, London, for duty as medical officer.

Flight Lt. J. Hill to R.A.F. Station, Singapore.

Dental Branch.—Squadron Leader G. A. Ballantyne, D.F.C., to R.A.F. Depot, Uxbridge, for duty as Senior Dental Officer.

INDIAN MEDICAL SERVICE

Maj. R. C. Phelps to be Lt.-Col.

The undermentioned officers have vacated appts. in India:—

D.A.D.H.—Capt. A. B. Guild, I.M.S.

D.A.D.P.—Maj. W. D. B. Read, I.M.S., and Lt.-Col.

D. T. M. Large, R.A.M.C.

The undermentioned appts. have been made:—

D.A.D.H.—Capt. V. E. M. Lee, I.M.S.

D.A.D.P.—Maj. R. A. Hepple, M.C., R.A.M.C.

The Commander-in-Chief has made the following appointments:—

Colonel R. P. Lewis, D.S.O., as Assistant Director of Medical Services, Deccan District, in place of Colonel E. C. Hodgson, D.S.O., retired.

COLONIAL MEDICAL SERVICE

Dr. D. H. K. Lee has been appointed Professor of Physiology, King Edward VII. College of Medicine, Singapore; Miss J. McDowall, M.B., Ch.B., Medical Officer, Palestine; Dr. A. A. Peat, Medical Officer of Health, Jamaica; and Dr. J. A. Waterman, Medical Officer (Grade I.), Trinidad.

DEATHS IN THE SERVICES

The death occurred on Dec. 2nd at Cheltenham of Lieut.-Colonel RICHARD PRATT BOND, who was born in 1856, received his medical education at King's College, London, and qualified L.R.C.P. Edin. 1880 and M.R.C.S. Eng. 1881. After serving as house surgeon at King's College Hospital and resident medical officer at the Royal Free Hospital, he joined the Army as surgeon captain in 1883, becoming lieut.-colonel in 1903 and retiring in 1911. He saw service in the Sudan from 1884-88 and in South Africa 1899-1902, receiving the Queen's medal with two clasps. In the European war he was re-employed as an A.D.M.S. at home.

OBITUARY

CHARLES RICHEL

Prof. Charles Richet died quietly at his home in Paris on Dec. 4th, after he had been ailing for some time from broncho-pneumonia. The son of Prof. Alfred Richet, he was born in Paris in 1850. His earlier works were chiefly concerned with physiology, and it was in 1887 that he was appointed professor. In 1898 he was elected to membership of the Academy of Medicine, and in 1914 to membership of the Academy of Sciences, whose president he was in 1933. Among the many honours awarded him was the Nobel Prize which he received in 1913.

PROF. RICHEL

[Photograph Wide World]

What is, perhaps, the most striking feature of Richet's long and distinguished career is the variety of the subjects to which he made fundamental contributions. He was a physiologist, pathologist, bacteriologist, psychologist, engineer (he devised an aeroplane), statistician, author, dramatist, and much else. The interest he took in every subject brought to his notice was characterised by a remarkable freedom from hard-

and-fast, pre-conceived notions. There was something paradoxical in the encyclopaedic dimensions of his knowledge and the facility with which he escaped from it all and with unhampered mind passed to new discoveries.

Richet's first physiological study concerned the composition of the gastric juice. Later, he investigated the physiology of animal heat and respiration, the control of the latter by the nervous system, and the regulation of the heat of the body by polypnoea and shivering. He showed that the respiratory exchanges are proportional to the surface of the body (Richet's and Rubner's law). In 1887 his investigations of cancer made him stumble on the discovery of anaphylaxis. He found in the tumour of a dog a staphylococcus resembling the *Staphylococcus albus* and growing easily on culture. This germ was injected under the skin of dogs in an attempt to reproduce the tumour, but the effect was a simple abscess which healed quickly. When, however, this germ was injected under the skin of rabbits, it provoked gangrenous abscesses, rapidly followed by a septicæmia which proved fatal in a day or two, and sometimes only in a few hours. Hence the qualifying adjective "pyosepticus" applied to this staphylococcus. It now occurred to Richet to introduce into the peritoneal cavities of rabbits the blood of dogs into which the *Staphylococcus pyosepticus* had previously been injected. The results of these experiments and the reflections to which they had given rise were communicated to the Academy of Sciences on Nov. 5th, 1888, by Richet and Héricourt. The title of their communication

was "Transfusion Péritonéale et l'Immunité qu'elle Confère." The gist of this thesis was that the blood of an animal immunised against an infection can, if introduced into another animal susceptible to the infection in question, enable this animal to acquire immunity to it. What was first known as hæmotherapy soon came to be called serotherapy. On Dec. 6th, 1890, at the Hôtel-Dieu, Paris, in Prof. Verneuil's service, Richet gave the first serotherapeutic injection into a human being. It was hoped that this discovery would be applicable to tuberculosis, but the researches pursued by Richet in this field proved disappointing. Meanwhile the same clue was yielding rich discoveries to Behring and Kitasato who had followed it in their therapeutic studies of tetanus and diphtheria. By 1899 the number of specific serums for the treatment of various diseases had risen to 45. When, in 1932, Richet reviewed his life's work in a communication to the Academy of Medicine, he did not venture to invade the realm of astronomical figures in an attempt to estimate the number of specific sera prepared up to date. But what he was successful in showing was the wealth and variety of the therapeutic advances which, since 1888, have their more or less distant roots in his original discovery. He dealt on this occasion not only with such definite achievements as the prevention of measles by the injection of the serum of convalescents from this disease, but also with his hopes that tuberculosis, syphilis, and cancer may all ultimately yield up their secrets in response to the clues he has provided. With regard to cancer he said: "It is also likely that anti-cancer serotherapy which, since 1895, has given us most encouraging results, has not said the last word, and that the investigations undertaken on every side with so much ardour to illuminate the ætiology of the disease will find their application in the preparation of a curative serum." On the same occasion he referred to the future of the serum treatment of tuberculosis; and he noted that encouraging results have already been obtained with tuberculous rabbits treated with the serum of goats or sheep into which filtrates alone of a culture of BCG, or such filtrates combined with a BCG culture, had been injected.

As recently as February, 1935, Richet took a prominent part in a discussion in the Academy of Medicine on the French birth-rate. The Russian statistician, Roubakine, had submitted to the Academy of Medicine figures and opinions which were eminently distasteful to most Frenchmen. Richet did not mince matters in his criticism of the Russian statistics which he compared with those of a certain humorist who published a work on the innocuity of falls from great heights, his argument being based on a dozen perfectly authentic cases in which falls from the fifth storey had inflicted only scratches.

Richet showed much courage and contempt for ridicule in his study of subjects supposed to be occult. He justified these studies by the strictly scientific technique he applied to them. His "Essai de Psychologie Générale" was published in 1890. In the same year he wrote "Possession" which was followed in 1892 by "Sœur Marthe." In 1893 he wrote "A la Recherche du Bonheur," in 1894 "A la Recherche de la Gloire," in 1895 "Conscience d'Homme," in 1898 "La Douleur des Autres," and in 1902 "Pour les Grands et les Petits." His interest in sociological problems found expression

in his work "Les Guerres et la Paix. le Passé de la Guerre et l'Avenir de la Paix." The title of a comedy he wrote was "Socrate." In 1926 the Academy of Medicine celebrated his scientific jubilee, and on this occasion Marshal Foch decorated him with the insignia of Grand Officer of the Legion of Honour.

**HAROLD PRINGLE, M.D. Dub., F.R.C.S.I.,
F.R.C.P.I.**

LATE KING'S PROFESSOR OF THE INSTITUTE OF MEDICINE AND
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF DUBLIN

THE retirement of Dr. Harold Pringle from his professorial duties in the School of Physic, Trinity College, Dublin, was mentioned in a recent issue of THE LANCET (Nov. 30th. 1935. p. 1261). He died on Dec. 7th at his residence, Sandford Grove, Dublin. Although for many months past no hope could be held out of recovery, his death has caused great grief to his friends and colleagues.

Harold Pringle was born at Clones, Co. Monaghan, nearly sixty years ago, and educated at Trinity College, Dublin. He qualified in medicine and surgery in 1899, and proceeded to the degree of M.D. in 1902, in which year he also took the diploma of F.R.C.S.I. A pupil in physiology of John Mallet Purser, one of the most notable teachers of his time, Pringle's tastes lay toward scientific rather than clinical work. Having held some minor appointments he became assistant to the late Sir Edward Sharpey-Schafer at Edinburgh, and was subsequently appointed lecturer in histology in that University. During the European War he served in France, most of his duty being along pathological lines. In 1918 Sir William Henry Thompson, King's Professor of the Institute of Medicine in Dublin, lost his life in the mail steamer *Leinster*, sunk off the Irish coast by enemy action. Shortly after Pringle was elected his successor and held the post until ill-health compelled his retirement a few months ago. In 1922 the University of Dublin established a Professorship of Physiology and appointed Pringle to the post, without, however, making any alteration in his duties. For several years past his colleagues showed their appreciation of Pringle's capacity by electing him unanimously as representative of the professorial staff on the Board of Trinity College.

His onerous duties as head of a great teaching department occupied most of Pringle's time, and he performed those duties with complete efficiency. His pupils received his individual attention, and those who showed any special interest in physiology were given every help and encouragement to carry their studies further. As a consequence his pupils came to regard him as a real friend. His colleagues found him unselfish, sympathetic, helpful, wise in counsel, and full of common sense and shrewdness. In social life he was the most pleasant of companions, humorous, cultivated, a good talker, and a stimulating listener, being not only witty himself but the cause of wit in others.

Two years ago he lost, in rapid succession, his wife and his eldest son—a youth of great promise; while he realised that his own health was beyond hope of repair. The courage and cheerfulness which he showed to the end increased the love and respect of his friends.

ROBERT EARDLEY-WILMOT, M.B. Lond.

Dr. Robert Eardley-Wilmot died at the age of 86 on Dec. 3rd; 60 years ago he made a mark as a young man in obstetric medicine. He received his medical education at King's College Hospital, took the English double diploma in 1871, and graduated

in medicine in the University of London in the following year with the university scholarship and gold medal in obstetric medicine. He was appointed house physician and, later, resident accoucheur for the diseases of women and children at his hospital, and made some practical communications on his subject to the Transactions of the Obstetric Society and to our own columns. Shortly afterwards he went to Leamington where he became visiting medical officer to the Midland Counties Home for Incurables, and wrote an essay on the natural mineral waters of Leamington. On retirement he lived at Petworth, Sussex, and was appointed a J.P. for the county, while he had previously been made a J.P. for the county of Warwickshire.

**ANDREW MACKENZIE ROSS SINCLAIR, M.B.,
C.M. Aberd.**

Dr. Ross Sinclair, who died late in November, was a successful and popular practitioner in Fulham and Wandsworth for the past 30 years. He received his medical education at Aberdeen, and graduated M.B., C.M. in 1893, having secured many prizes and medals in the course of his career, both in preliminary and final subjects. Shortly after graduation he began practice in London and served as clinical assistant at the Chelsea Hospital for Women, the St. Mark's Hospital, St. Peter's Hospital, and the West London Hospital; thus he possessed a wide range of practical knowledge when he started as a general practitioner. He soon acquired a large connexion and a high reputation in his locality, while he did much voluntary service outside his professional engagements as medical adviser to athletic clubs, in which connexion he was also surgeon to the Hurlingham Polo Club. He leant strongly towards specialism in the direction of nose, ear, and throat diseases, was surgeon to the ear, nose, and throat department of the L.C.C. school clinic at Bagleys-lane, and at the time of his death he had commenced special practice in Queen Anne-street. Dr. Sinclair was 69 years of age.

EDWARD ROBERTS, M.R.C.S. Eng., L.S.A.

THE death occurred recently in a London nursing-home, after operation, of Mr. Edward Roberts, for many years surgeon to the Manchester Royal Eye Hospital. He was 78 years of age. He received his medical education at Guy's Hospital, and obtained his English diplomas in 1883. In that year he obtained honours in the intermediary examination for the M.B. Lond. but did not proceed to graduation. He was appointed resident obstetric officer to Guy's Hospital, after filling which post he became house surgeon to the Royal Eye Hospital, Manchester. Here, after five years as an interne, he was elected surgeon to the hospital and also ophthalmic surgeon to the Chorlton Union Hospital. During this period he contributed articles on his subject to the Transactions of the Manchester Pathological Society and to our own columns. On retirement from Manchester he went to live at Aberlloelwyn, near Aberystwyth, and became a prominent supporter of the Aberystwyth Infirmary and Cardiganshire General Hospital, of which institution he was president at the time of his death.

WE noted in a recent issue (August 17th, p. 405) the celebration of the centenary of Dr. Griffith Evans, and took the occasion to write a short biography. We regret to learn that Dr. Evans died on Saturday last, Dec. 7th, at Brynknallt.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

The Debate on the Address

In the House of Commons on Dec. 4th, in the resumed debate on the Address, Mr. ARTHUR GREENWOOD said that if there were to be educational developments, improvements in the health services, and better housing for the people no one would be more pleased than the Labour Party. They were grateful for these proposals in the King's Speech—for what they were worth—but considered that the Speech lacked coherence. The old economic forces could no longer be allowed to operate in the way they had done in the past: the country must either plan or perish. There must be planning under public ownership and public control, with public spirit in the public interest, and it was because the present Government could not possibly live up to that kind of policy that it would be strenuously opposed.

Sir FRANCIS ACLAND said he was disappointed that there seemed to be no prospect of further legislation on housing. What was said in the Gracious Speech came simply to this, that the Acts passed last year and previously would be allowed to take their course. That was really not enough. It was hopeless to expect that houses would be built at rents which working-class people could afford to pay in country districts under any legislation now on the Statute Book.

Mr. F. ANDERSON said that medical officers of health were stating that the application of the means test was leading to a high maternal death-rate, increasing tuberculosis, and damaging the nutrition of children. He appealed to the Government to look at this question from a humanitarian point of view.—Viscountess ASTOR said that Mr. Anderson had referred to the malnutrition of the children, but it was one of the glories of the National Government that the health of the country had never been better than it was last year. They had not got to the bottom of the question of maternal mortality. The Government in the Gracious Speech had taken a welcome step in the proposal that there should be salaried midwifery, but she did not think that even that was going to solve the problem.—Mr. GALLACHER said that maternal mortality came from low wages and low unemployment relief. The mothers and the children had to suffer.

Sir FRANCIS FREMANTLE was glad that the Speech contained a definite promise of attention to physical education, and spoke of the useful work being done by a Lucas-Tooth gymnasium in Tooley-street for unemployed men from the northern coalfields and elsewhere. He hoped that in the general improvement of the school medical arrangements the greatest possible care would be taken to coördinate the system of school medical work with the general medical provisions for the health of the people, not merely during school years but afterwards, and that there would be a continuity of inspection and assistance. The gap before school life started had been largely filled, and he hoped that the other gap between school life and the employment age would now be filled. He regretted that there was no allusion to the bringing of town-planning schemes into force at once, while all the building was going on, and he hoped a plan for immediate action could be brought into effect. He wished to add his voice to the hopeful expectation of the measure to be introduced with regard to an organised service of salaried midwives, but pointed out that difficulties would have to be faced when the measure was introduced. It raised many thorny issues, including the whole question of a salaried service and how far the State was to support any one profession, however useful. How far would it be possible to arrange coöperation between the local authorities and the voluntary

associations so as not to spoil voluntary effort already in existence? If such coördination could be got he hoped all parties would join in giving the Bill an unopposed passage so that it might become law before the House rose for the summer holidays.

POVERTY AND MALNUTRITION

On Dec. 6th, when the debate was resumed, Mr. BOOTHBY said that the problem of poverty in the midst of plenty remained despite the revival in many industries during the past two years. The way to deal with this problem was to promote increased consumption by any and every means, rather than restrict production in order to keep up prices. The acid test of capitalism to-day was whether it could swing over sufficiently from the production of capital goods. The same problem was facing Russia. The problem was both international and national, and he thought that the last meeting of the Assembly of the League of Nations was very encouraging, because in the midst of a great international crisis they devoted three days to discussing the problem of under-nourishment and of increasing consumption throughout the world. What had we done in this country in this direction? The only real success had been the wheat subsidy. The milk position was getting better now, but until they started tackling distribution it had done nothing but raise prices to the consumer and diminish consumption. Experiment was admittedly necessary, but it seemed to him entirely wrong to approach this question, especially where subsidies were concerned, from the point of view of the producer rather than the consumer. He wanted to direct the attention of the House to the investigations reported by Sir John Orr, head of the Rowett Research Institute. He had, for instance, taken the average diet of some of the children in the town of Peterhead and compared it with the ideal diet which was not very much more expensive. He (Mr. Boothby) had seen rats fed on these diets and the difference between them was absolutely fantastic; moreover the relative immunity of the ideally fed rats from disease was very striking. Sir John Orr's tentative conclusion was that diseases due to malnutrition, or to wrong nutrition, were still very prevalent, particularly in the distressed areas. He had also come to the conclusion that food was much more important than housing. Often rent was paid at the expense of food, and he (Mr. Boothby) thought that the claims of housing were now emphasised a little too much and at the expense of food. Nobody denied that houses were valuable, but where the need was desperate food was much more important. Cheap food meant less poverty, less disease, and a lower cost of social services in the long run. Sir John Orr pointed out that 10s. per head per week taken as the expenditure on food, which was the lowest level, meant a consumption of one pint of liquid milk per head per week, which was grossly and totally inadequate. With wages of £2 and over the consumption at once rose to five pints per head; and the same thing happened with regard to eggs and fruit, with enormously beneficial results. Sir John Orr said that if the diet of all families with an income of less than £1 per head per week could be raised to the point attainable by this level it would mean 10 per cent. increased consumption, or £100,000,000 a year increase at retail prices. Sir John's suggestion was that there should be public utility corporations to manage the processing centres, and that they should buy direct from the farmer at a price to be fixed by them and sell direct to the distributor at a price also to be fixed by them and published, thus cheapening the cost of distribution and enabling the public to know exactly how much they ought to pay in the shops for their food-supplies. These proposals ought to receive the very serious consideration of the Government. He agreed with the Labour Party

that one step to be taken in the way of increasing general purchasing power would be the abolition of the family means test, though he did not believe that they could abolish the means test altogether. He also wanted to put in a plea for a more ambitious policy with regard to the provision of milk for children, especially in the distressed areas. Liquid milk should be given absolutely free to children under five years of age and to mothers as well. He would also like to see a much more intensive propaganda among the working classes with regard to the kind of food they ought to eat.

After further debate, Lord EUSTACE PERCY, Minister without Portfolio, said that the whole investigation on which Sir John Orr's figures were based was promoted and carried on by the Government and publication of those figures was designed to awaken public attention to the real need for and the possibilities of a policy of nutrition. If they repeated in the future the growth in consumption which was actually realised in the period 1924-32 they would for most of the commodities have solved nearly the whole problem. For only a few commodities like fish—and strangely enough cheese—would they need any very much greater increase in consumption than was realised in that earlier period. He claimed that the policy which the Government had been pursuing was in its broad outline the policy which was likely to assist such a growth in consumption.

The debate was adjourned.

Employment of Women and Young Persons

On Thursday, Dec. 5th, in the House of Commons Sir J. SIMON, Home Secretary, presented a Bill to make provision for the employment of women and young persons in factories and workshops on a system of shifts. The Bill was read a first time.

HOUSE OF COMMONS

THURSDAY, DEC. 5TH

The Needs Test Regulations

Mr. GRAHAM WHITE asked the Minister of Labour if it was his intention to publish the report of the Unemployment Assistance Board on the working of the needs test regulations.—Lieut.-Colonel MUIRHEAD, Parliamentary Secretary to the Ministry of Labour, replied: It is not yet possible to say precisely what documents will be laid before the House but it will be my right hon. friend's object in due course to supply hon. Members with all relevant information regarding the working of the present arrangements.

The Means Test and the Anomalies Act

Mr. MANDER asked the Minister of Labour what steps the Government proposed to take to abolish the household means test.

Mr. STEPHEN asked the Minister of Labour if he was aware of the widespread dissatisfaction in the country with the means test and the Anomalies Act; and whether he would introduce legislation at an early date for the abolition of the means test and the repeal of the Anomalies Act.—Lieut.-Colonel MUIRHEAD replied: The policy of the Government with regard to the means test has already been made clear. As was stated by the Prime Minister on Tuesday, it is hoped to lay proposals before Parliament not long after the end of the Christmas recess. There are no proposals in contemplation for repealing the Anomalies Act.

Sterilisation of Barbers' Implements

Mr. HICKS asked the Minister of Health if he was prepared to make an order to compel hairdressers and barbers to sterilise brushes, combs, razors, and other implements used in the course of their trade, with a view to preventing the dissemination of vermin and skin and other diseases.—Sir KINGSLEY WOOD replied: I am advised that as a general rule there is little risk of such a state of uncleanness in a hairdresser's establishment as to cause or promote the spread of disease, and as at present advised I do not think it is necessary to make such an order as is suggested by the hon. Member.

Mr. HICKS: Has the right hon. gentleman no information of cases where disease has been spread owing to the fact that the tools used in barbering have not been thoroughly sterilised?

Sir KINGSLEY WOOD: I have not heard of any cases.

Survey under Overcrowding Act

Mr. GRAHAM WHITE asked the Minister of Health if he could make a statement with regard to the progress made by local authorities in carrying out the survey of conditions of overcrowding under the Housing Act, 1935.—Sir KINGSLEY WOOD replied: I have fixed April 1st, 1936, as the date by which the survey should be completed, and I have every reason to believe that local authorities generally will complete the task in the allotted time. In most areas the survey has already started or will be commenced at an early date.

Public Assistance

Sir JOSEPH NALL asked the Minister of Health whether he was aware that public assistance committees, in computing need, were taking into consideration the additional 1s. per week for a child recently granted in unemployment benefit; whether it was intended that the additional 1s. should be so taken into consideration; and what guidance was being given to public assistance committees in the matter.—Sir KINGSLEY WOOD replied: The duty of a public assistance authority is to assess the needs of an applicant for relief which he cannot meet from his own resources, and in doing so they have no power to ignore unemployment benefit. There are, however, very few cases in which it is found necessary to supplement benefit by relief, and I do not think that it is necessary for me to give any special guidance in the matter.

Health Insurance and the Provision of Milk

Lieut.-Colonel MOORE asked the Minister of Health whether, with a view to improving the nation's health, he would consider the introduction of a scheme for enabling milk to be prescribed as well as medicine under the national health insurance scheme in cases where doctors were of the opinion that the health of the insured person in question would benefit thereby.—Sir KINGSLEY WOOD replied: The National Health Insurance Acts provide only for the supply of medicines and approved appliances, and there is no power to introduce the scheme suggested by my hon. friend. Extensive provision has been made in the schemes administered by local authorities acting as local education authorities and as maternity and child welfare authorities for the supply of milk free and at reduced rates to those to whom it is specially valuable and who are found to require this supplementation of their diets.

The Driving Test

Mr. MAGNAY asked the Minister of Transport the proportion of failures in the driving tests set by the examiners of the Ministry of Transport.—Mr. HORE-BELISHA replied: Up to and including Nov. 30th, 166,855 persons have been examined, of whom 24,803 failed to satisfy the examiner.

MONDAY, DEC. 9TH.

Supplies of Milk to Poor Children

Mr. THOMAS WILLIAMS asked the Minister of Agriculture whether his department and/or the Milk Marketing Board had considered a scheme for supplying cheap or free milk to school-children on non-school days and to children of poor parents between the age of 1 year and 5 years; and, if so, with what result.—Mr. ELLIOT replied: Under the existing arrangements the scheme for the supply of milk-in-schools in England and Wales at reduced rates may operate seven days a week and throughout the holidays, provided the children are assembled for the purpose. Careful consideration is being given to the possibility of introducing an experimental scheme for the supply of milk at reduced rates to children below school age in the special areas, but I am not in a position to make any statement on the subject.

Small Traders and Voluntary Insurance

Mr. TINKER asked the Minister of Health if he was aware that many persons in a small business of their own were

anxious to become contributors to the national health insurance scheme for the purpose of becoming entitled to a pension at the age of 65; and if he would examine this question to see if it could be made workable.—Sir KINGSLEY WOOD replied: The Government have indicated their intention of introducing a scheme of voluntary insurance for pensions purposes. The details of this scheme are now under consideration, but it is intended that the scheme shall be open to certain classes of persons, including the class referred to by the hon. Member, which are outside the scope of the compulsory scheme.

The New Milk Order

Mr. THOMAS WILLIAMS asked the Minister of Health whether he had received any complaints regarding the draft of the new Milk Order; and, if so, if he would state the source of the complaints and his reply.—Sir KINGSLEY WOOD replied: I have received representations from a large number of sources on various points arising on the draft order. I am at present considering these representations in consultation with my right hon. friend the Minister of Agriculture, and I hope shortly to issue a revised draft of the order.

National Parks

Mr. EDE asked the Minister of Health if he intended to introduce legislation this session to implement the recommendations of the departmental committee on national parks.—Sir KINGSLEY WOOD replied: I can hold out no hope of legislation this session. By the exercise of their powers, particularly under the Town and Country Planning Act, 1932, local authorities are making steady progress in the acquisition and reservation of land for public open spaces and in the control and premature building operations and will continue to receive all the help and encouragement in these matters which I am able to give them.

Accidents to Young Persons in Factories

Mr. LOVAT-FRASER asked the Home Secretary if he was aware that the figures of accidents to young persons in factories had gone up from 17,000 in 1934 to over 21,000 in 1935, largely owing to the lack of concentration brought about by long hours of work; and if he would take steps to deal with this evil.—Mr. GEOFFREY LLOYD (Under-Secretary to Home Office) replied: The accident figures quoted are those for 1933 and 1934. There was also a large increase in 1934 in accidents to adults, and both increases were, I am advised, due mainly to more extensive employment consequent on the greater industrial activity. I am aware that in some cases this has led to longer hours, but how far fatigue has contributed to accidents among young persons it is not possible to say. As stated by the Prime Minister in debate on the 3rd instant, it is the hope and purpose of the Government to introduce in their second session a Bill to revise and consolidate the Factory Acts.

TUESDAY, DEC. 10TH

Suicides in the Army

Mr. MAXTON asked the Secretary of State for War the number of officers and men in the Army who had committed suicide during the last twelve months, and whether any inquiry, other than coroners' inquests, had been made into the circumstances.—Mr. DUFF COOPER replied: The number of suicides in the Regular Army during the last twelve months, at home and abroad including India, has been: one officer and 36 men. Four of these were the subject of courts of inquiry.

National Health Insurance Cards

Mr. RHYS DAVIES asked the Minister of Health whether he was aware that officers of approved societies were complaining that blank health insurance cards for the first half of 1936 were issued later this time than usual; and if he could give any reason for the delay.—Sir KINGSLEY WOOD replied: The health insurance cards for the first half of 1936 were sent to approved societies at a rather later date than usual. On this occasion it was necessary to print not only 20 million cards, the form

of which had been entirely recast, but also the same number of leaflets explaining to insured persons the important changes made by the amending Act recently passed.

Overcrowding Surveys by Local Authorities

Mr. HERBERT WILLIAMS asked the Minister of Health what progress had been made in the surveys by local authorities under the provisions of the Housing Act, 1935, to determine the extent of overcrowding in their respective areas.—Sir KINGSLEY WOOD replied: I have fixed April 1st, 1936, as the date by which the survey should be completed, and I have every reason to believe that local authorities generally will complete the task in the allotted time. In most areas the survey has already started or will be commenced at an early date.

Free Insulin for Diabetics

Mr. GEORGE GRIFFITHS asked the Minister of Health if he was prepared to make arrangements for all diabetics who had run out of insurance benefit to be given insulin free without any means test.—Sir KINGSLEY WOOD replied: I have no power to make such arrangements, but as the hon. Member is aware, local authorities are empowered to provide insulin for persons in need of it who are unable to purchase it out of their own resources.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 30TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2963; diphtheria, 1413; enteric fever, 27; acute pneumonia (primary or influenzal), 848; puerperal fever, 38; puerperal pyrexia, 101; cerebro-spinal fever, 12; acute poliomyelitis, 13; acute polio-encephalitis, 1; encephalitis lethargica, 6; continued fever, 1 (Lewes); dysentery, 48; ophthalmia neonatorum, 60. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Dec. 6th was 3364, which included: Scarlet fever, 1189; diphtheria, 1283; measles, 119; whooping-cough, 276; puerperal fever, 21 mothers (plus 12 babies); encephalitis lethargica, 279; poliomyelitis, 6. At St. Margaret's Hospital there were 14 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 6 (2) from enteric fever, 25 (0) from measles, 7 (1) from scarlet fever, 10 (0) from whooping-cough, 27 (3) from diphtheria, 35 (4) from diarrhoea and enteritis under two years, and 58 (11) from influenza. The figures in parentheses are those for London itself.

The deaths from enteric fever outside London occurred at Bury, Stockport, Sunderland, and Leicester. Manchester reported 10 deaths from measles, Liverpool 4, Bootle 3, and Blackburn 2. The deaths from diphtheria were reported from 20 great towns, 3 from Manchester, 2 each from West Ham, Liverpool, and Newcastle-on-Tyne. The mortality from influenza is scattered over 32 great towns, Birmingham reporting 6, Manchester 4, Liverpool and St. Helens each 3.

The number of stillbirths notified during the week was 248 (corresponding to a rate of 41 per 1000 total births), including 38 in London.

BIGGER HOSPITAL AT EALING.—A scheme is on foot to add 78 beds to Ealing Hospital, making about 200 in all. The cost of the extensions is put at £100,000.

NEW MENTAL HOSPITAL FOR WEST KENT.—The committee of the Kent county council, appointed to consider the care of mental patients, has recommended that a new area be created for West Kent. A site of not less than 200 acres is to be purchased in the Dartford rural district for the erection of a mental hospital for 1200 patients. The capital cost of the institution, exclusive of land, is expected to be about £660,000.

VOLUNTARY EUTHANASIA

THE inaugural meeting of the Voluntary Euthanasia League Society was held on Dec. 10th at B.M.A. House, Tavistock-square.

Lord MORRIS, who presided, said that this was the first chance there had been of putting the aims of the society before a public meeting, of giving unanswerable reasons in favour of their view, of meeting arguments, and of overcoming the prejudices which existed in the minds of the lay public. Their object was to obtain legal recognition of the principle that, in cases of inevitably fatal disease in which agony reaches or oversteps the limit of human endurance, the sufferer should have the right to demand, and the doctor to give, relief. In spite of the greatly strengthened capacity of physicians and surgeons to relieve pain, there were still cases in which it could be said with certainty that the agony was intense and the fatal issue inevitable. The society had no intention to seek to include any other cases but these. They were not asking permission to end the lives of Mongolian idiots, of the subjects of senile dementia or other mental disease. They asked for authority only in the case of incurable disease in which the pain is intense. There were denominations within the Christian Church whose members had no right to such relief as that for which sanction was desired; these persons were asked to stand aside.

Dr. C. KILLICK MILLARD (hon. secretary of the society) read apologies for absence from Lord Ponsonby, Sir F. Menzies, F.R.C.P., Sir P. C. Varrier-Jones, F.R.C.P., Mr. McAdam Eccles, F.R.C.S., Prof. Julian Huxley, Sir Arnold Wilson, M.P., Miss Eleanor Rathbone, M.P., and others. Miss Rathbone had sent a letter promising her support in Parliament and saying that the movement appealed particularly to women, and letters of support were read from Sir John Robertson, late M.O.H. of Birmingham, the Rev. S. M. Berry, an American doctor, and a woman surgeon. Prof. Creed, professor of divinity in the University of Cambridge, wrote that if the proposed action was duly safeguarded it appeared to him to be a duty to God and to man to abbreviate such suffering when the sufferer himself desired it.

INDIVIDUAL AND SOCIAL ASPECTS

Mr. C. J. BOND, F.R.C.S., chairman of the executive committee, said that the introduction of the subject in its present form dated from Dr. Millard's address to the Society of Medical Officers of Health on Oct. 16th, 1931. He proposed to say a few words on the individual and the social aspect of the problem of euthanasia. On the individual aspect everyone, especially doctors, would welcome the change that has taken place in public opinion concerning suicide in recent years. Instead of regarding the person attempting suicide as a criminal, an effort was now made to deal with the troubles which had led to the tragedy—the alcoholism, the domestic unhappiness, the anxiety about work, or the mental instability—and if friends or relations were willing to accept the responsibility of looking after the sufferer, he was placed under their care.

This change of attitude had an important bearing on the present movement to place voluntary euthanasia on a sound, legal basis.

The social aspect of the problem was equally important. The free discussion which would undoubtedly follow the introduction of the proposed Bill into Parliament would have a profound educational effect on public opinion. Civilised man was to-day being called upon to exercise increasing

control over human development and human life, and this meant control at both ends, at entrance into, and exit from life. In order to exercise this control wisely, a truer conception was needed of the real value of life which consisted not merely in living, but in living usefully and happily. Where there was no hope of cure or restoration to health and usefulness the wish of the sufferer to be allowed to terminate a burdensome and unhappy existence should be respected. It was also well to remember that ours is an ageing population, and that thus the total amount of suffering and of useless lives grows larger, and requires wise handling and more efficient relief. A matter for consideration was whether the legalisation of voluntary euthanasia would tend to weaken the moral fibre of the nation, to lessen endurance and, by example, to lead to a more easy acceptance of defeat on the part of persons confronted with insurmountable difficulties in other departments of life. Mr. Bond did not think it would have any such effect. Even if voluntary euthanasia was legalised, it would still be possible for anyone who thought it his duty, and who wished to do so, to struggle on to the end. The decision to end a suffering life that has become a burden to others would in itself require courage and a high sense of duty.

The position and duty of the doctor in the matter of euthanasia was admittedly a difficult one. It was his duty to relieve suffering by every means in his power. But the sufferer might become habituated to the drug used to relieve pain. Very large doses were then required, and the balance between an analgesic and a lethal dose became a very delicate one. Moreover the repeated returns to consciousness, which it was difficult to avoid, might be a very depressing and sad experience. In fact the actual prolongation of life by the use of drugs might itself increase the total amount of suffering. If the proposed Bill became law, the doctor would be able to deal with the suffering more effectively; his position must be defined and legalised, and then what was now being done secretly, and often ineffectively, could be done openly on a legalised basis. Those who had been instrumental in bringing this subject of voluntary euthanasia before the public had been much encouraged by the widespread support with which their proposals had been received. Many of the objections which had been raised could be overcome, and those which rested on a misconception of the objects aimed at, would, they hoped, be removed by further discussion. Meanwhile, helpful criticism and useful suggestions would be welcomed. Mr. Bond said a word in conclusion about the letters and statements which had appeared in the press. An article which spoke of the proposed Bill as a "Bill to promote murder" and of a doctor who helps a sufferer to end his sufferings in a legalised way, as a "public executioner" was entirely beside the mark. The doctor should be compared rather with an anaesthetist who specialised in the art of preventing pain by inducing insensitivity to pain. A doctor who would assist his patient to end his sufferings by euthanasia would act as an anaesthetist, the difference being that the relief he gave was permanent and not merely temporary. Mr. Bond expressed the belief that the wish to help in the relief of human suffering would induce many to join this movement. They were concerned to-day only with voluntary euthanasia and the provisions in the proposed Bill, but as public opinion developed, and it became possible to form a truer estimate of the value of human life, further progress along preventive lines will be possible. It would then be apparent to what extent help could

be given to cases which from the very beginning were hopeless.

Dr. C. KILICK MILLARD (hon. secretary of the Society) said that much of the pain and suffering in the world was due to certain diseases, which not only killed their victims, but killed them by the slow, lingering process of exhaustion due to pain and suffering—a process often long drawn out over a period of many weeks or even months. All through the world's history there had been those who have wondered whether all this pain and suffering in the process of dying from incurable disease was really necessary; whether it was really God's will; or whether it might not be right, under certain circumstances, to substitute for the lingering and painful death a quick and painless one. Many people to-day thought that the law which prohibited such a course needed emendation. As the law now stood, anyone, no matter how great his sufferings or how certain his doom, who took upon himself to terminate his life or even deliberately to shorten it by a single day was guilty of suicide (a felony); whilst anyone who aided and abetted him, no matter how merciful and disinterested his motives, was guilty of murder. The Society thought that the present law, in this respect, was harsh and unmerciful, and out of harmony with the humanitarian spirit of the age.

SUGGESTED CHANGES IN THE LAW

The Voluntary Euthanasia Legalisation Society has been formed for the express purpose of bringing about a change in the law, so that it might be legally possible for a person who had attained the age of 21 years and was suffering from incurable, fatal, and painful disease, to be granted euthanasia—i.e., easy death—if he so desires, without committing any offence or incurring any stigma. The Society, acting under expert legal advice, had accordingly prepared a Bill, the Voluntary Euthanasia (Legalisation) Bill, to give effect to this reform, and it is one principal object of the Society to get this Bill passed into law.

The procedure provided for in the Bill was briefly as follows:—

The sufferer must sign an official application form (not merely scribble his request on a half sheet of paper), and his signature must be duly attested by two witnesses, one of whom (referred to as the official witness) must be of a certain specified status—e.g., lawyer, doctor, minister of religion, &c. This is to safeguard against any undue pressure by interested relatives at the time of signing.

In addition, the patient must obtain two independent medical certificates, also on official forms, to the effect that in the opinion of the doctor signing the certificate, the patient is suffering from disease of an incurable, fatal, and painful character.

The application and the two medical certificates must then be sent to an official appointed for the purpose, to be known as the euthanasia referee. It will be his duty to satisfy himself, by a personal visit and otherwise, that the application and certificates are all in order, and that the case is a proper one to be granted euthanasia.

If the euthanasia referee is satisfied, he will grant the necessary permit, but the Bill provides that an interval of seven days must elapse before the permit may be acted upon. There is obviously a necessity to interpose some delay.

It has been thought well in the Bill to give to friends, acting through the "nearest relative" as defined in the Bill, a right of appeal to a court of summary jurisdiction, on the ground that all the necessary conditions have not been complied with. The mere fact that the friends object on principle to euthanasia is not sufficient. Probably, in practice, the right of appeal would seldom be exercised.

The medical practitioner who is to administer euthanasia would be named on the permit, and he must be one who holds a licence for this purpose from the Minister of Health:

The Bill had been criticised on the ground that the procedure outlined above was too elaborate and cumbersome, and that it would unduly deter sufferers from applying for the relief. Another objection was that the seven days' delay was too long. If it was thought desirable to simplify the procedure and shorten the time, no objection would be made by the promoters. But the procedure being an irrevocable step must be very carefully guarded against over-hasty action or the possibility of abuse.

OBJECTIONS TO BE MET

The objections to the proposals might be classed under three heads: (1) moral, (2) legal, (3) practical. As regards (1) this was at once the greatest and the least of the difficulties. The strength of the sincere opposition on moral grounds was not minimised. But it must be remembered that only *voluntary* euthanasia was asked for. If the individual sufferer concerned had himself no religious scruples about receiving euthanasia, he ought not to be prevented merely because someone else might have scruples.

As to (2), the legal objections, little serious criticism had been received from the legal profession, but it was recognised that what was suggested was a radical departure from traditional and existing law, and it was to be expected that the representatives of the law should demand adequate and ample safeguards against possible abuse before approving of the proposed reform. The promoters submitted, however, that the present position in which doctors were sometimes impelled, from motives of mercy, to give an overdose of sleeping draught to a patient suffering intolerable pain, and do so, to a large extent, with the approval of public opinion, was very much more open to abuse than anything proposed under the Bill.

As to (3), practical objections, these had all been carefully considered and could, he believed, be met. (a) It was said that even though euthanasia were legalised there would be no demand for it. This was disputed. Not all people cling to life; the demand might be small at first, as with cremation, but it would increase under the force of example. (b) The uncertainty of diagnosis and prognosis was emphasised. Doctors were not infallible, and patients given up as hopeless had sometimes recovered. A certain element of risk in this respect must be admitted, but the patient must take this risk just as he has to do in deciding whether to undergo some major operation. The argument would have more weight in the case of compulsory euthanasia, but human fallibility was not considered a sufficient argument against the compulsory taking of life in the infliction of capital punishment. (c) It was urged that there would be great difficulties in carrying out the proposed scheme, and that it would be unworkable in practice. The promoters contended that the difficulties were certainly not insuperable. (d) The question of possible abuse had already been referred to under legal objections. When the battle for cremation was being fought it was urged that the burning of the body would enable the poisoner to effectually destroy the evidence of his crime; practice had shown that this objection was far less serious than a priori it was thought to be. (e) Lastly, it was said that there would be certain concomitant disadvantages if euthanasia were legalised—e.g., mental distress to the patient through having to decide whether or not to apply for euthanasia. Conscientious persons, although not wishing to die, might feel that it was their duty to relieve their friends of the burden of looking after them in their

last illness. It was submitted that this disadvantage was small in comparison with the great advantages the Bill would confer. Moreover, one effect of legalising euthanasia would be that it would tend to make patients who did not want to apply for it more inclined to bear their pain patiently, which would be all to the good. There is also the possibility of dissensions being caused amongst relatives on the question whether or not to oppose or accede to a sufferer's desire to apply for euthanasia. This was hardly a very serious objection; relatives were apt to quarrel over many things. Against all these objections, and any others which might be brought forward, must be set the great advantage to be gained by the relief of suffering.

The Voluntary Euthanasia Legalisation Society would welcome criticism, especially constructive criticism regarding the provisions of the Bill, the exact details of which were not to be regarded as necessarily final. They asked only that their opponents should be fair and should not misrepresent them as asking for something which in fact they were not asking for.

SUPPORT FROM VARIOUS QUARTERS

The Earl of LISTOWEL said that as a member of the House of Lords he knew the difficulty of altering even the most antiquated law. If they were to be successful in amending the legal code by introducing a piece of progressive legislation they must get support from every quarter of public opinion. "As the first layman to speak from this platform" he desired to express gratitude to those members of the medical profession who had taken the initiative in this campaign and had not feared to seek the burden of additional grave responsibility. The layman owed the profession a debt for the encroachment which it had made on human suffering and that debt would be increased so long as the profession continued to produce men such as those present on the platform. To the ordinary man there could be no more distressing or tragic experience than to watch one he loved sinking toward the grave, and that distress was increased a thousand fold when the friend or the relation had to pass the last moments in a state of the utmost agony. There was a sphere within which pain could be diminished by morphia and the like. By the introduction of voluntary euthanasia they would carry on further the great battle against suffering which the men of science had waged. For all Christians the greatest of all commandments was the exercise of mercy. The quality of mercy should be extended to the dying.

The Rev. HAROLD ANSON, Master of the Temple, said he did not represent the Church of England, but a certain body of opinion within that church including among others Dr. Inge, Canon Sheppard, and two professors of divinity. He believed there was no religious or moral objection to the course proposed. The views of the Church were subject to change. Truth was progressive. It used to be believed that every birth was endowed by God. That opinion had changed, and so too opinion as to the providential character of death must be changed. Judgment must be used as to whether the pain of disease answers any good ethical purpose. If not, it was a duty to do away with pain, when it could be lawfully done away with, and this must apply to the end of life. However, medical men must be satisfied, and legal men must be assured that the procedure could be carried out without danger to relatives. If those two points of view were satisfied there was

nothing in the teaching and philosophy of religion to prevent the exercise of human reason in this matter.

The Rev. F. W. NORWOOD, D.D., said the principal concern of religion was more with the entrance and conduct of life than with its exit. He was troubled not so much as to whether people should be allowed to leave life when its misery was unendurable, but rather why they should have to meet such misery in life. A society which rained death on all ages of both sexes was unduly squeamish if it disallowed those suffering intolerable agony to leave life if they wished. Religion which refused to believe in an indifferent or a punitive God, which called on people to make themselves superior to flesh, to believe that Christ has brought immortality to life, and regards death as going out to meet the Heavenly Father, could not enforce the necessity of escaping from life in a loathsome penthouse of pain, seeking not for God but for extinction. Religion which allowed capital punishment but did not allow it as a spectacle, should not allow the hopeless watching of the death agonies of the loved ones. Religion which regarded medical science as a gift of God should not condemn that science, when it could not cure pain, to prolong it. Why had religion tolerated so long an attitude abhorrent to its deepest instincts and its teaching? The medical profession at least had an opiate to offer; the others had nought save counsel and advice. Few ministers could not tell stories to wring the hearts of all sane persons. He himself had long felt the present condition to be an anomaly and hoped that this movement would end it.

Mr. ROBERT HARDING described how a harrowing and prolonged personal experience had made him rush to welcome this movement, which might save others from the miseries which he had to endure.

A number of written questions were sent up to the platform and were answered by the speakers there.

AN OBJECTION

Dr. C. O. HAWTHORNE then rose to explain why he was against the proposal and pointed out that though the meeting was in the house of the B.M.A. that body had nothing to do with the movement. He regarded the state of affairs in which the proposal was to be justified as an exceptional and rare condition. The remedy proposed was an enormous change, for the sake of an infinitesimal amount of good. Deliberate extinction of life was a principle likely to have extension and repercussion. A patient suffering severe prolonged pain was in no state of mind to exercise calm and collected judgment or to appreciate the issues involved in his decision. The friends and relations might be equally ill-balanced through grief and worry. There was something repulsive in the idea of sons and daughters sitting round a table and discussing whether their parent should be encouraged or deterred from a method of suicide. The final sentence according to the proposal would be passed by a magistrate, who might make a mistake, and the executive officer was to be the doctor, also not infallible. Moreover, many doctors would decline. It was not necessary to have any technical equipment to poison a patient; the right person to perform that office would be a relation or intimate friend.

The resolution, "that in the interests of humanity, it is desirable that voluntary euthanasia should be legalised, subject to adequate safeguards, for persons who are suffering from incurable, fatal, and painful disease," was put to the vote and carried by a show of hands.

MEDICAL NEWS

University of London

A special advisory board has been constituted to deal with questions relating to the academic post-graduate diploma in dietetics, and regulations for the award of the diploma will be issued later.

The following examiners have been appointed for 1936 :

Second Examination for M.B., B.S.—Anatomy: Dr. John Kirk, Prof. H. H. Woollard, Prof. A. B. Appleton, Prof. T. B. Johnston, Prof. William Wright, Dr. Thomas Yeates, and Prof. J. E. S. Frazer. *Pharmacology:* Prof. J. H. Gaddum, Dr. O. Inchley, Dr. Philip Hamill, Dr. V. J. Woolley, Dr. Nathan Mutch, Prof. Samson Wright, Dr. Eleanor Scarborough, and Prof. A. St. G. J. M. Huggett. *Physiology:* Prof. J. C. Drummond, Prof. J. P. Hill, F.R.S., Dr. W. H. Newton, Prof. R. J. S. McDowall, Dr. G. W. Nicholson, Mr. W. R. Spurrell, Prof. D. T. Harris, Prof. E. C. Dodds, Mr. J. H. Woodger, D.Sc., Prof. Samson Wright, Prof. Winifred Cullis, and Prof. Huggett.

Second and Third Examinations for B.D.S.—Anatomy: Prof. Wright and Prof. Woollard. *Physiology:* Prof. Harris and Mr. Spurrell. *Prosthetic dentistry:* Mr. J. B. Milne and Dr. E. W. Fish. *Special anatomy, special physiology and dental histology:* Mr. T. W. Widdowson (one internal examiner to be appointed). *Medicine:* Dr. C. E. Newman and Dr. K. E. Harris. *Surgery:* Mr. E. C. Hughes and Mr. Alan Perry. *Pharmacology:* Mr. Frank Coleman and Dr. W. A. M. Smart. *Pathology and bacteriology:* Prof. C. C. Okell and Mr. Arthur Bulleid. *Dental surgery and operative dental surgery:* Mr. E. C. Sprawson and Prof. E. B. Dowsett. *Orthodontics:* Mr. Harold Chapman and Mr. S. F. St. J. Steadman.

Diploma in Clinical Pathology.—Prof. E. C. Dodds, Prof. James McIntosh, and Prof. J. Shaw Dunn.

Diploma in Public Health.—Part I.: Prof. M. E. Delafield, Prof. W. W. C. Topley, F.R.S., Prof. Okell, and Prof. H. B. Maitland. Part II.: Prof. M. Greenwood, F.R.S., Prof. W. V. Jameson, Prof. R. M. F. Picken, and Dr. Alexander Joe. *Hospital administration:* Dr. Joe.

Dr. J. C. Thomas has been appointed Graham scholar in pathology for two years in succession to Dr. E. S. Duthie, who has been appointed assistant pathologist to the Royal Hospital, Sheffield.

University of Bristol

Dr. N. J. England has been successful in obtaining the degree of M.D.

National University of Ireland

The degree of M.D. has been awarded to Dr. M. Harris O'Connor.

University of Dublin

At recent examinations at the School of Physic, Trinity College, the following candidates were successful:—

FINAL MEDICAL EXAMINATION FOR THE M.B., B.CH., B.A.O. (PART II.)

Medicine.—Bethel Lapedus, S. J. H. Douglas, Benjamin Rogol, G. S. Caithness, H. B. Sutton, R. C. O'Grady, W. S. M'Bride, E. S. Dorman, G. H. B. Roberts, D. P. Harris, D. H. T. Duggan, and L. W. McCaughey (old regulations).

Surgery.—S. J. H. Douglas, D. H. T. Duggan, B. E. T. Aldwell, J. C. Gaffney, A. F. H. Keatinge, Emanuel Cowan, H. C. Bourke, B. M. O'Sullivan, H. B. Sutton, G. W. M. Elliott, S. B. Sachs, D. P. Harris, J. A. Hamilton, J. T. Wellwood, E. S. Dorman, J. R. Shapiro, Philip Citron, R. C. O'Grady, and P. St. G. Robinson.

Midwifery.—H. S. Boyce, W. A. Gillespie, G. W. Patterson, Mandel Friedman, W. D. Chesney, and Max Levy.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS

B. E. Wurm.

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty held on Dec. 2nd, with Prof. Archibald Young, the president, in the chair, the following were admitted to the fellowship: John Charles Alexander, M.B., William Herbert Brown, M.D., and James Gibson Graham, M.D. (Glasgow); Andrew Fergus Hewat, M.D. (Edinburgh); and Isaac Chesar Michaelson, L.R.C.P. Edin. (Glasgow).

The president intimated that the faculty had received a legacy of £600 from the estate of the late Dr. Freeland Fergus, who was its president during the years 1919–22.

Air Hygiene Foundation of America

This foundation has been formed, with headquarters at Thackeray-avenue and O'Hara-street, Pittsburgh, Pa., to investigate air contamination and disseminate information. Research has begun at the Mellon Institute of Industrial Research, Pittsburgh, under the direction of Mr. H. B. Meller, with Prof. Samuel R. Haythorn as medical adviser.

THE King has given permission to Dr. G.W. Spencer to wear the insignia of the fourth class (civil division) of the order of Al Rafidain which has been conferred on him by the King of Iraq for his services as chief ophthalmic specialist in the Iraq health service.

THE death occurred at Canford Cliffs, Bournemouth, on Dec. 6th, of Mr. Henry Walter Pigeon, M.B. Camb., F.R.C.S. Eng., consulting surgeon to the Hull Royal Infirmary.

Bernhard Baron Trust

Under the terms of this trust grants to hospitals and charities are made every year on Dec. 5th, the birthday of the late Mr. Bernhard Baron. This year £41,317 is being distributed and the grants include £16,200 to London hospitals and £9640 to hospitals outside London. Since the fund was created in 1928 over £300,000 has been distributed.

Certifying Factory Surgeons

The annual dinner of the Association of Certifying Factory Surgeons was held at the Langham Hotel, London, on Dec. 5th, Dr. A. Glen Park (Bolton) presiding. In proposing the toast of the Factory Department of the Home Office Dr. W. H. F. Oxley (London) recalled the earliest festive meal in 1901 of which Dr. V. A. Jaynes and Dr. J. A. P. Barnes were, he thought, the only other survivors present. He criticised the use of the word "young person" in the Factory Act, preferring the word "children"—which was indeed used by subsequent speakers—and credited the department with having been the means of stopping the terrible exploitation of child labour; but the number of factory inspectors was still too small, and eternal vigilance was still needed. The standard set by Whitelegge and Legge was not an easy one to live up to. A welcome change in the work of certifying surgeons was due to the fact that children could now, and mostly did, pick and choose their own jobs. The few shillings brought in weekly by these children was a real asset in the family budget, providing as it did the additional vitamins A and D so needful for vigour. The Association's work was preventive medicine applied to the individual, and as such it should, he thought, remain the general practitioner's job.

Mr. D. R. Wilson, H.M. chief inspector of factories, who replied, said he was a great believer in tradition, and the certifying factory surgeon dated from 1844. His was one of the oldest of official medical appointments. It was a heterogeneous system that worked well in practice. Central appointment of certifying surgeons left the selection free from bias, local or political; appointment of local practitioners gave the desirable link in continuity, for the certifying surgeon remained in the same place and was familiar with the local industries, their risks, and the indications of exposure to these risks; moreover, he came into contact with the local employers of labour. The charge of perfunctory work was simply not true; many of the surgeons spent much time on their reports. His own feeling was that the present fees were inadequate, that there should be more contact between the school and the factory (one obvious way would be by continuity of records), and that the effect of occupation on the youngster should be ascertained by re-examination after (say) six or twelve months. Dr. S. A. Henry, a senior medical inspector of factories, who also replied, regretted the absence of the eleven women factory surgeons but was glad to see there three full-time works doctors. He thanked factory surgeons for help rendered outside their statutory duties. Appointed as he was by a State Department, the factory surgeon was endowed with impartiality as between employer and employed, an inheritance to be guarded.

Sir Francis Fremantle, proposing The Association, said that the medical officers of health, to whom he belonged, originated in 1847, three years after the certifying factory surgeons, and the two had grown up side by side out of general practice. He was sorry that the Association only included some 280 of the 1700 to 1800 factory surgeons;

if all were members they could speak with more unity and authority. He agreed that the break between school and industrial life must be bridged. Dr. Park, responding, opened with a tribute to Thomas Percival (1740-1804) and the Manchester Board of Health. From a small beginning the medical section of the factory department had now grown to eight full-time officers. Certain enlightened firms were already examining industrial recruits up to 18-20 years; he would like to see systematic investigation of adults absent from industry through illness, and this need not clash with the work of the family doctor. The toast of The Visitors was proposed by Dr. O. Field, and the Rt. Hon. J. R. Clynes, M.P., in reply, recalled the time when "as a little black-haired nipper of ten" he had to pass the works doctor. He would like to see medicine brought ever more closely in touch with industry, particularly in the direction of informing the worker better about the risks and dangers of his work. Sir Henry Fildes, M.P., also replied. Finally, on the proposal of Mr. C. Entwistle, M.P., the President was toasted with acclamation.

Royal Surgical Aid Society

The Lord Mayor of London, Sir Percy Vincent, who presided at the seventy-third annual meeting held at the Mansion House on Dec. 9th, congratulated the society on its splendid work and said that the legacies received during the year amounted to £12,733, a record sum. Special effort was, he said, being made for one of the depressed areas, Durham; with £1450 already collected 300 dentures had been supplied, and he appealed for more. Prof. G. Grey Turner, who proposed the vote of thanks to the surgeons and the staff, said it was a great comfort to the operating surgeon to feel that, having done what he could in the way of surgery, the patient was to be looked after and his requirements met by a philanthropic body such as this. He mentioned the late Mr. Muirhead Little, who was associated with the work of the society for 40 years. Mr. E. Laming Evans, replying for the staff, spoke with satisfaction of the establishment of an ophthalmic department which would supply properly prescribed and tested glasses to those needing them.

Society of Apothecaries of London

Sir William Willcox presided, as master, over a yeomanry dinner held last Tuesday at the Apothecaries' Hall in Water-lane. Sir Humphry Rolleston, an honorary freeman, proposing the toast of the Society, described it as a happy combination of ancient tradition and modern activity. Its prestige had been increased by the distinction of its recent masters and Sir William added to that distinction. He fitted into the surgeon's definition of a surgeon, for he was "a physician and something more"—a toxicologist, an adviser of judges, and a sportsman with horse and gun. Sir Humphry rejoiced that the master had come back from the end of the world with every one of his fellow-travellers of the British Medical Association safe and sound. Replying, Sir William said that while some people climbed the ladder of fame, Sir Humphry Rolleston had been raised there by the affection and esteem of the whole of the medical profession. In his own travels in Australia what had impressed him most had been the all-round efficiency of the men who had to practise medicine under difficult conditions and their interest in what was written and thought in this country. Turning to the Society's affairs he spoke of his regret that owing to illness Sir George Buchanan had not been able to play his full part as master during the year; his duties had been fulfilled by Dr. Wakelin Barratt, past master. As the most active of the few really active city companies in London, the Society retained its close connexion with its guild, the medical profession, and he would advise all young medical men to join it. The Society also helped those seeking qualification: for while its examinations maintained a standard as high as those of the universities and joint colleges they were held more frequently and lower fees were charged. Dr. A. P. Gibbons, senior warden, proposed The Guests, naming among them Sir George Chrystal, secretary to the Ministry of Health, Sir Henry Gauvain, Lieut.-General Sir James Hartigan, Air-Commodore A. W. Iredell, Sir Henry Dale, Dr. G. C. Anderson, and the deans of the faculties of medicine of Oxford, Cambridge, Cardiff, and Leeds, of

the medical schools of Charing Cross, King's, St. Mary's, St. Thomas's, Westminster, and of the London School of Hygiene. Sir Arthur Robinson, chairman of the Supply Board, responding, spoke of his long and happy associations with the Society when he was secretary to the Ministry of Health. Mr. S. P. Vivian, the Registrar-General, also responding, produced some useful hints, derived from Anglo-Saxon medical works, about the burial of badgers at the gates of boroughs, which he thought might be made the subject of a memorandum to borough councils from the Ministry. After quoting a French statesman who at an official dinner referred to the menu as "the list of the causes of death" he ended with a felicitous quotation from Thackeray about the well-being of those who attend the feasts of doctors. In Thackeray's words, "Ask us again, dear Sirs."

First-aid Course in Chemical Warfare

The British Red Cross Society has arranged a course of eight lectures on first aid in chemical warfare for doctors and trained nurses. The lectures, which will be held on Mondays and Wednesdays at 8 P.M., will begin on Jan. 27th. Applications should be sent to the matron-in-chief of the society at 14, Grosvenor-crescent, London, S.W. 1, before Jan. 8th.

Insurance against Broken Spectacles

The fear of breakage is said to be a serious deterrent against the purchase of spectacles and other optical goods such as cameras, field-glasses, telescopes, and microscopes. Moreover, the expense of repairs leads to delay in bringing them back to the maker after they have been broken. To meet this trade problem a policy of insurance has now been devised by the Eagle, Star, and British Dominions Insurance Co., Ltd., Threadneedle-street, London. While the company is prepared to issue individual policies to wearers of glasses of any type or to users of other optical instruments, it is expected that group policies issued through optical dealers will be more generally useful. Under this scheme the optician will be able to issue an insurance policy with every pair of glasses he sells, thus ensuring that if breakage or loss takes place the customer will return to him for the necessary repair or replacement—and return promptly. The premium for spectacles on policies issued to individuals will be 5s. on the first pair, 4s. on the second pair, and 3s. 6d. on each subsequent pair. Where group policies are issued to opticians, however, special rates will be quoted.

The New Ilford Radiographic Department

Sir Ivor Philipps, chairman of Ilford Ltd., opened a new radiographic department on Dec. 2nd. The department, which is on the first floor of Tavistock House North, contains well-equipped X ray and dark rooms, a studio for clinical photography, lecture and exhibition rooms, all under the charge of Miss K. C. Clark, with the assistance of Messrs. A. E. Dean and Co. in keeping the X ray apparatus up to date. Capt. T. Midgley Illingworth, director of Ilford Ltd., who welcomed the visitors, said the department had been set up with the idea of being of service to radiography, and it would be conducted on professional lines. Sir Ivor said he hoped the department would serve as a convenient meeting place for those interested in radiography, and a place where the technique of X ray photography could be developed and discussed. The expert staff would render assistance in overcoming any difficulties and problems arising in practice. Clinical photography was also being provided for. Dr. Duncan White said that, although at the present time throughout the country there were many places offering excellent tuition in the value of radiography, there was hardly any centre where practical instruction was given. This was of supreme importance both to the radiologist and the radiographer. He had himself given up much time to coaching would-be radiologists how to use the X ray apparatus at a certain hospital without interfering with the routine work of the department. He visualised the Ilford Radiographic Department serving as a centre where radiologists or radiographers in the early days of their search after knowledge might come for a period to be instructed, to beware of the pitfalls, and to learn something of the fascination of the art of radiography.

Nuffield House, Guy's Hospital

Since 1884 private paying patients have been admitted to cubicles in Bright's ward in Guy's Hospital. Now, thanks to the generosity of Lord Nuffield, the accommodation available for such patients has been increased by the erection of a four-storied block containing 70 beds (50 in private rooms and 20 in cubicles), two operating theatres, and an X ray room. The cubicles at 5 guineas a week are reserved for patients with an income under £350 (single person), £450 (married), and £550 (married with children under 21); the private rooms (7 to 12 guineas) are available without restriction to patients of any income under the care of any "person of consultant rank," subject to the approval of the medical superintendent of the hospital. The fees in all cases include maintenance, nursing, and drugs. The Prince of Wales opened Nuffield House, which is situated at the southern end of the open space known to Guy's men as "The Park," on Dec. 10th, and said that King Edward's Hospital Fund for London regarded the provision of pay-beds as a very valuable addition to the voluntary hospital service of the city. He also announced that Lord Nuffield has succeeded Mr. F. P. Whitbread as treasurer to Guy's Hospital.

Grove Hospital, Tooting

Last Friday, Dec. 6th, Mr. W. R. Owen, on behalf of the Medical Services Committee of the L.C.C., opened at Grove Hospital, Tooting, the new block which has been built as part of the general scheme for the extension of isolation accommodation in London. It is two storeys in height and provides accommodation for 60 patients in single-bedded wards separated by partly glazed screens, with duty rooms so placed that the nurses will be able to keep every patient under observation. Each ward is 11 by 10 feet and 9 feet high, giving a cubic space of 990 feet. Among those present at the ceremony, in addition to members and officers of the London County Council and members of the Grove Hospital committee, were Alderman A. J. Hurley, representing the Mayor of Wandsworth, representatives of the Ministry of Health, the town clerk, and the medical officer of health for Wandsworth and medical officers of other metropolitan boroughs.

Fellowship of Medicine and Post-Graduate Medical Association

The special courses during the early part of 1936 will include the following: dermatology at the St. John's Hospital (Jan. 2nd to 30th); cardiology at the National Hospital for Diseases of the Heart (Jan. 13th to 24th); urology at St. Peter's Hospital (Jan. 20th to Feb. 1st); proctology at St. Mark's Hospital (Feb. 3rd to 8th); neurology at the West End Hospital for Nervous Diseases (Feb. 3rd to 8th); gynaecology at the Chelsea Hospital for Women (Feb. 10th to 22nd). Week-end courses will be given on heart and lung diseases at the Royal Chest Hospital (Jan. 18th and 19th); and in physical medicine at the St. John Clinic and Institute of Physical Medicine (Feb. 8th and 9th). A course of surgical tutorial lectures, which are intended for F.R.C.S. (Final) candidates, will be held on Tuesday and Thursdays at 8.30 p.m. at the National Temperance Hospital from Jan. 14th to March 5th. The full list of special courses for the year will be ready shortly and may be obtained on application to the secretary of the Fellowship, 1, Wimpole-street, London, W.1.

Appointments

DRAINER S. K., M.B. Glasg., D.P.H., has been appointed Assistant Medical Officer for the County of Aberdeen.
DUCKWORTH, GEOFFREY, M.R.C.P. Lond., Hon. Physician in Charge of the Skin Department at the East Ham Memorial Hospital.
HANCOCK, P. E. T., B.Chir. Camb., M.R.C.P. Lond., Medical Registrar at the Cancer Hospital (Free), London.
PENMAN, G. G., M.D. Camb., F.R.C.S. Eng., Ophthalmic Surgeon in charge of out-patients, St. Thomas's Hospital. (Corrected notice.)
SHELLEY, URSULA, M.D., M.R.C.P. Lond., Hon. Assistant Physician to the Princess Louise Kensington Hospital for Children.
SMALL, H. A. D., M.B. N.Z., Resident Medical Officer at the Cancer Hospital (Free), London.

STURROCK, G. M., M.B. Edin., F.R.C.S. Edin., Assistant Visiting Surgeon to the Dundee Royal Infirmary.

Queen Charlotte's Maternity Hospital.—The following appointments are announced:—

PURDIE, A. W., M.B. Glasg., Senior Resident Medical Officer;
HARBUTT, S. W. J., M.B. N.Z., Assistant Resident Medical Officer; and

OLDFIELD, JOSIE M., M.R.C.S. Eng., Resident Anaesthetist and District Resident Medical Officer.

Medical Officer's Department, Birkenhead.—The following appointments are announced:—

BLACKSTOCK, ERIC, M.D. Belf., D.P.H., Additional Assistant Medical Officer;

HERP, S. B., M.D. Liverp., M.C.O.G., Consulting Gynaecologist and Obstetrician; and

CHARTERS, D. L., M.B. Glasg., Consulting Ophthalmologist.

Certifying Surgeon under the Factory and Workshop Acts:
Dr. W. D. MACKINNON (Portree (Isle of Skye) District, Inverness).

Births, Marriages, and Deaths

BIRTHS

FITZGERALD.—On Dec. 2nd, at Lucknow, the wife of Major G. H. FitzGerald, I.M.S., Bareilly, of a daughter.

GANNER.—On Dec. 6th, at Birmingham, to the wife of Philip J. Ganner, F.R.C.S. Eng., a son.

GRIFFITHS.—On Nov. 30th, at Bentinck-street, W., the wife of J. Ivor Griffiths, F.R.C.S. Eng., of a son.

HENDLEY.—On Dec. 3rd, at Wrotham, Kent, the wife of Dr. H. J. H. Hendley, of Brasted, of a son.

MCCAY.—On Nov. 29th, at Calcutta, the wife of Frank McCay, M.D. Camb., of a daughter.

MCLAUGHLIN.—On Dec. 8th, at Sheffield, the wife of Dr. A. I. G. McLaughlin, of a son.

PULVERTAFT.—On Dec. 10th, at Ebnal Dyke, Gobowen, Salop, to Betty (née Willock), wife of Guy Pulvertaft, F.R.C.S.—a son.

WIGHT.—On Nov. 24th, at Wangford, near Beccles, the wife of Cecil H. Wight, M.C., M.R.C.S. Eng., of a daughter.

MARRIAGES

PEARSON—KEATING.—On Dec. 7th, Hubert Edward Spencer Pearson, M.R.C.P. Lond., to Ruth Monica Keating.

PETERKIN—ELDER.—On Nov. 30th, at St. Andrew's Church, Edinburgh, George Alexander Grant Peterkin, M.B. M.R.C.P. Edin., to Alison Anne Macainsh, daughter of the Rev. Hugh and Mrs. Elder, Moffat.

STEPHEN—ROYCE.—On Dec. 3rd, at St. John's Church, Westminster, Robert Alexander Stephen, M.D., Captain, R.A.M.C., to Audrey Vivien, youngest daughter of Mr. George Wm. Royce, Cambridge.

THORNTON—BECHER.—On Nov. 23rd, at Baghdad, Thomas Thornton, M.D. St. And., F.R.C.S. Eng., of Dundee, to Joan Becher, of Bexhill.

TOWNSEND—LAW.—On Nov. 30th, R. L. H. Townsend, B.M. Oxon., of Bulawayo, to Brenda, eldest daughter of Mr. C. A. Law, of London.

DEATHS

BABINGTON.—On Dec. 5th, suddenly, Stanley Noel Babington, M.R.C.S. Eng., of Leicester, aged 64.

EARDLEY-WILMOT.—On Dec. 3rd, at Petworth, Sussex, Robert Eardley-Wilmot, M.B. Lond., J.P., aged 86.

EVANS.—On Dec. 7th, at Brynkynallt, Bangor, N. Wales, Griffith Evans, M.D. McGill, D.Sc. Wales, late Inspecting Veterinary Surgeon, Army Department, in his 101st year.

HICKLEY.—On Nov. 26th, at Bromley, Kent, Arthur Mackenzie Hickley, M.R.C.S. Eng.

LONDON.—On Nov. 25th, at Lee Green, S.E., Ernest E. B. London, M.R.C.S. Eng.

MACLAGAN-WEDDERBURN.—On Dec. 7th, at North Berwick, Laurence Craigie MacLagan-Wedderburn, M.D. Edin.

MILLS-ROBERTS.—On Nov. 27th, at Bournemouth, Lieut. Colonel Robert Herbert Mills-Roberts, C.M.G., J.P., F.R.C.S. Edin., of Plas Meini, Festiniog, Merionethshire.

MOORE-GRAHAM.—On Nov. 26th, in London, George Robert Moore-Graham, L., L.M., K.Q.C.P. Irel., of Melbourne, Australia.

PERRIN.—On Dec. 8th, after a short illness, at Upper Wimpole-street, W., Walter Sydney Perrin, M.Chir. Camb., F.R.C.S. Eng.

PIGEON.—On Dec. 6th, at Bournemouth, Henry Walter Pigeon, M.B., M.C. Camb., F.R.C.S. Eng., formerly of Hull, aged 76.

ROBERTS.—On Nov. 30th, at a London nursing home, Edward Roberts, M.R.C.S. Eng., of Aberlholwyn, Llanfarian, Cardiganshire.

RUSHWORTH.—On Nov. 28th, at Walton-on-Thames, Norman Rushworth, M.R.C.S. Eng.

SHAW.—On Dec. 2nd, at Haditha, Iraq, Frederick Roland Studdert Shaw, M.C., M.B. Dubl., late Major, R.A.M.C., Chief Medical Officer, Iraq Petroleum Co.

SMITH.—On Dec. 7th, at Hove, Thomas Morland Smith, M.R.C.S. Eng., late of Bournemouth.

WARD.—On Dec. 7th, at The Sanatorium, Pietermaritzburg, Charles Ward, F.R.C.S.I., in his 85th year.

YOUNG.—On Dec. 6th, at Yarmouth, Isle of Wight, Samuel Leggett Orford Young, M.D. Camb., late of Freshwater, I.W., aged 58.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THORACOPLASTY IN SCANDINAVIA

ALL over the world an endeavour is being made to discover the surest and safest means of securing effective closure of cavities in the lung. One of the most interesting publications of recent years on this subject is by Johan Holst, Carl Semb, and J. Frimann-Dahl (*Acta chir. Scand.*, 1935, lxxvi., Suppl. 135). This paper is an extremely frank exposition of the results of various modifications of thoracoplasty tried by the authors. A recent modification which has given them their most successful results is the addition of Semb's technique for apicolysis in conjunction with thoracoplasty. Even the most extensive rib resection, with total extirpation of the first and second ribs, does not always (it is stated) achieve reliable collapse of cavities of the upper lobe. When, however, the extrafascial apicolysis of Semb is combined with this extensive thoracoplasty it is possible to obtain "effective selective collapse of the cavity and low mortality."

Semb describes his technique in another part of the same volume (*ibid.*, p. 84). The main principle is the division of the upper intercostal muscles, vessels, and periosteum, which attach the lung to the chest wall, combined with the separation of all the extrafascial bands which hold the apex up to the neurovascular structures at the root of the neck and to the vertebral column. As a result of this the apex of the lung, with the cavity, can be displaced downwards; the cavity is flattened from above downwards and it shows less tendency to re-expand. The results within the first two months of 133 operations, quoted in this paper, are as follows. Of 77 cases in which the extrafascial apicolysis was combined with resection of 6 ribs 2 only died. There were 4 deaths out of 35 cases in which 7 or 8 ribs were resected; 4 deaths out of 21 when the apicolysis was combined with the resection of 9 to 11 ribs. In 90 per cent. of the cases collapse of the cavity could be seen on the screen, and the sputum was free from tubercle bacilli in 80 per cent.

In the combined paper the post-operative complications were studied. Attention is called to the frequency of atelectasis in varying degrees; it occurred in about half the cases. Its frequency increased with the size of the operation, and with immobilisation of the diaphragm—a strong argument against preliminary phrenicectomy. The authors summarise the risks of thoracoplasty as "essentially dependent upon the extent to which the expectoratory ability is impaired and retention of bronchial secretion occurs after the operation. The expectoratory ability is impaired by: extensive resection of ribs, suspended mobility of the diaphragm, and poorly fixed mediastinum."

Both papers are full of instructive information.

THE EVOLUTION OF HEARING AIDS

THE portable hearing aid in common use consists of a small microphone, a dry battery, and a receiver; it has been improved in detail of recent years, but suffers from several inherent defects, the result of its necessarily small size and light weight. The receiver may be a disc-shaped ear-piece, a small "button" which fits into the meatus, or a bone-conductor to be worn on the mastoid. The microphone is usually of the carbon granule variety, which is noisy when moved, works only in the upright position, emits "frying" sounds when it becomes worn or dirty, and rapidly loses efficiency as the surface of the granules become worn. The dry battery, also, quickly loses the greater part of its efficiency, and must be frequently renewed. A microphone amplifier is now often added to the instrument, especially when a bone-conductor receiver is employed, but this uses considerable more current and so exhausts the battery sooner.

The great disadvantage of these hearing aids is that the amplification is very uneven; it is usually

greatest at about 1000 cycles a second and falls off rapidly on either side, so that tones above 3000 to 4000 cycles are not amplified at all. In consequence the hearing of speech is but little improved, and such sounds as the letter S are inaudible; music is so distorted as to be unpleasant. With a larger apparatus, especially with valve amplification, these difficulties can be largely surmounted; a less sensitive but more efficient microphone can be employed, and a small accumulator may take the place of the dry battery. In consequence there is less background noise and, what is more important, a uniform or "straight-line" amplification can be obtained, or this can be increased over the higher or lower end of the scale as desired.

The apparatus is contained in a box, the bulk and weight of which was formerly a drawback, but small and light appliances are now obtainable. One of these is the Amplivox.¹ This has two-valve amplification, and a microphone containing fine carbon particles which works in any position; it is run from a small accumulator giving 60 hours' intermittent use, and a high-tension dry battery lasting from four to six months; a disc or button ear-piece may be used, or a bone-conductor can be supplied, but the makers claim that the instrument is so efficient that the latter is seldom required. Straight-line amplification is normally employed, but a low-tone ear-piece can be fitted, or a tone-control for special cases. The whole is contained in a neat leather box 6½ by 3½ by 4½ inches. An even smaller model has recently been produced measuring 5 by 2½ by 4 inches, with a 20-hour accumulator, and a smaller high-tension battery. The larger model is preferable if its size is not considered a drawback. Both instruments cost from 15 to 17 guineas; the makers claim that the cost of upkeep is but a few pence a week, and it is certainly less than that of the usual "portable" type of hearing aid where the expense of replacing dry batteries is considerable.

The apparatus which we examined gave ample volume, a quiet background, good audibility at the length of the room, and a noticeable absence of distortion; it should be far more useful than the ordinary micro-telephone aid, and especially for use at board meetings, theatres, and concerts.

A METHOD OF PAINLESS LABOUR

IN the *Journal* of the Canadian Medical Association for November L. C. Conn and J. R. Vant discuss a number of sedatives and anaesthetics for the relief of pain during labour. The drugs and method to which they give their chief support require, as they themselves insist, either that the patient shall be in an institution or else that she shall, if at home, be under the constant supervision of a medically qualified person. Their choice is for the combination of Nembutal by the mouth with paraldehyde, given per rectum half to one hour later. As a result of their investigation of a series of over four hundred confinements with various anaesthetics they find that this combination did increase the necessity for the use of "low forceps." The method must be started early in labour if it is to be of real value.

NEW PREPARATIONS

PHOSPHO-SODA (FLEET).—This is described as "a pure, non-toxic, highly concentrated, aqueous solution of the primary sodium phosphate, or monosodium phosphate." It thus differs from sodium phosphate B.P. which is di-sodium hydrogen phosphate, and is recommended as being "the same buffer salt that occurs naturally in the blood stream to regulate the body fluids." The Anglo-French Drug Co., Ltd. (11, Guilford-street, London, W.C.1), who introduce it in this country, claim that it has particular value as a saline aperient, cholagogue, and biliary stimulant, acceptable to a sensitive stomach.

¹ Amplivox Ltd., 106, George-street, London, W.1.

and not irritating to the intestinal mucosa. Its action is regarded as less drastic than that of magnesium or sodium sulphate, causing no griping at the time of evacuation. In small repeated doses it acidifies the urine, and it is considered a useful adjuvant to hexamine.

CORAMINE AS CARDIAC STIMULANT.—In our account of a sectional discussion at the Royal Society of Medicine a month ago (*THE LANCET*, Nov. 16th, p. 1122) one of the speakers is reported as saying that "he was rather surprised to hear that coramine was a cardiac stimulant, as he thought Bernard Myers's work had revealed a depressant action on the heart." We understand that the actual reference was to certain experiments made some years ago by Dr. G. Norman Myers, of Cambridge, which were performed on the isolated heart and have not been published.

Vacancies

For further information refer to the advertisement columns
All Saints' Hospital, Austral-street, West-square, S.E.—Res. H.S.
At rate of £100.

Army Dental Corps.—Commissions.
Ashford Hospital, Kent.—Res. M.O. £150.
Bath, Royal United Hospital.—H.P. At rate of £150.
Bechuanaland Protectorate Medical Service.—Two M.O.'s. Each £550.

Benenden, Kent, National Sanatorium.—Jun. H.P. At rate of £150.

Birmingham, Children's Hospital.—H.S. Also Cas. H.S. Each at rate of £75.

Birmingham Maternity Hospital.—Res. M.O. and Reg. £200.

Blackburn Royal Infirmary.—Res. H.P. £175.

Brighton, Royal Alexandra Hospital for Sick Children.—H.P. £120.

Brisbane, Queensland University.—Professorship of Physiology.

Bristol General Hospital.—Res. Surg. O. and Reg. £200. Also two H.P.'s, three H.S.'s, Res. Obstet. O., H.S. to Spec. Depts., also Cas. H.S. Each at rate of £80.

Cardiff, Llandough Hospital.—Jun. Res. M.O. At rate of £100.

Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.—Hon. Third Asst.

Chelsea Hospital for Women, Arthur-street, S.W.—Surgeon.

Derbyshire Royal Infirmary.—Ophth. H.S. and Anaesthetist. £150.

Doncaster Royal Infirmary.—H.P. At rate of £175.

Dover Royal Victoria Hospital.—Res. M.O. £180.

Dublin University.—Chair of Human Anatomy and Embryology, &c. £1100.

Durham, County Council, Education Dept.—Asst. School. M.O. £500.

Eastbourne, Royal Eye Hospital, Perensy-road.—H.S. £100.

East Grinstead and District New Hospital.—Hon. Consultants to Special Depts.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Hon. Clin. Assts. to Med. Out-patients' Dept.

Exminster, Devon Mental Hospital.—Jun. Asst. M.O. and Pathologist. £350.

Great Yarmouth General Hospital.—H.S. £140.

Hammersmith Metropolitan Borough.—Two Asst. M.O.'s. Each £500.

Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Res. H.P. At rate of £100.

Huddersfield Royal Infirmary.—Res. Surg. O. £225-£250.

Hull Royal Infirmary.—Res. Surg. O. £200.

Ilford, West Ham Mental Hospital, Goodmayes.—Jun. Asst. M.O. £350.

Kent and District General Hospital.—Hon. Dermatologist.

Leeds, —Sen. Asst. Res. M.O. £425.

London, —street.—Surg. Reg. £100.

Manchester, —Asst. Pathologist. £300.

Manchester Royal Children's Hospital.—Pendlebury, Res. M.O. At rate of £125.

Manor House Hospital, Golders Green, N.W.—Jun. M.O. £200.

Marie Curie Hospital, 2, Fitz-John's-avenue, N.W.—Res. M.O. At rate of £100.

Middlesex Hospital Medical School, W.—Clin. Asst. to Clinical Research Inst. At rate of £125.

Miller General Hospital, Greenwich-road, S.E.—Hon. Dental Surgeon.

Newcastle-upon-Tyne Royal Victoria Infirmary.—Res. H.P.'s and Res. H.S.'s. Also Anaesthetists. At rate of £50-£100-£200.

Northumberland County.—Sen. Tuberc. O. £1000.

Nottingham General Hospital.—H.S. At rate of £150.

Queensland University School of Medicine.—Professorship of Anatomy. Also Lectureship in Physiology.

Radium Institute, Riding House-street, W.—Asst. M.O. At rate of £250.

Redhill, Reigate Institution, St. John's.—Res. Asst. M.O. At rate of £250.

Rochdale Infirmary and Dispensary.—Sen. H.S. £250.

Royal College of Surgeons of England.—Examiner in Dental Surgery. Also Member to Court of Examiners.

Royal Masonic Hospital, Ravenscourt Park, W.—Res. M.O. £300.

Royal Northern Hospital, Holloway, N.—Hon. Radiologist.

Royal Waterloo Hospital for Women and Children, Waterloo-road, S.E.—Hon. Clin. Asst. for Ophth. Dept.

Royal Westminster Ophthalmic Hospital, Broad-street, W.C.—Asst. Surgeon.

St. Mary's Hospital, W.—Jun. Asst. Radiologist. £75.

St. Thomas's Hospital, S.E.—Obstet. Gynaecologist.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Radiologist.

Sheffield, Jessop Hospital for Women.—Sen. Res. O. Also two H.S.'s. At rate of £150 and £100 respectively.

Sheffield Royal Infirmary.—Clin. Asst. to Surgical Dept. At rate of £300.

Shoreham-by-Sea, Southlands Hospital.—Jun. Asst. Res. M.O. £250.

Singapore, Straits Settlements Mental Hospital.—Asst. Med. Supt. £700.

Staffordshire General Infirmary.—H.P. and Cas. O. At rate of £150.

Stoke-on-Trent, North Staffordshire Royal Infirmary.—Orthopaedic H.S. At rate of £150.

Surrey County Council.—Asst. M.O. £600.

Swansea General and Eye Hospital.—Res. Anaesthetist. £150.

West London Hospital, Hammersmith-road, W.—Med. Reg. £250.

Westminster Hospital, Broad Sanctuary, S.W.—Three Surg. Reg. Each £250.

Weston-super-Mare General Hospital.—Res. H.S. £150.

Wickford, Essex, Runwell Hospital.—Deputy Med. Supt. £650.

Wigan, Royal Albert Edward Infirmary and Dispensary.—Two H.S.'s. Each at rate of £150.

Wilkesden General Hospital, Harlesden-road, N.W.—Res. Cas. O. At rate of £100. Also Hon. Clin. Assts. to Out-patient Depts.

Wolverhampton Education Committee.—Asst. M.O. £600.

York County Hospital.—Asst. H.S. and Res. Anaesthetist. £150.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Shepshed (Leicester) and Alva (Clackmannan).

Medical Diary

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, Dec. 17th. 5.30 P.M. General Meeting of Fellows
Ballot for election to the Fellowship.

THURSDAY

Dermatology. 5 P.M. (Cases at 4 P.M.) Dr. H. W. Barber: 1. Lichen Planus with Herald Patches. Dr. R. D. Moyle: 2. Psoriasis with Lesions in the Mouth. Dr. W. J. O'Donovan: 3. Delayed Radium Burn. Dr. G. B. M. Heggs: 4. Pemphigus Vegetans. Dr. G. B. M. Heggs and Mr. F. A. Williamson-Noble: 5. Pseudoxanthoma Elasticum showing Fundus Changes. Dr. Murray Stuart (introduced by Dr. G. B. M. Heggs): 6. Multiple Xanthoma in a Child. Dr. F. Parkes Weber: 7. Morphea (Atrophoderma) Guttata or a Nevroid Condition, in a Young Man with Acromegaloïd Hands and Feet.
Neurology. 7.45 P.M. (National Hospital, Queen-square, W.C.) Clinical Meeting.

HUNTERIAN SOCIETY

MONDAY, Dec. 16th.—8.30 P.M. (Simpson's Restaurant, Bird-in-Hand-court, Cheap-side, E.C.) Dr. Brincker and Dr. Lennox Wainwright: Measles.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Thornhaugh-street, W.C.

FRIDAY, Dec. 20th.—5 P.M., Dr. Henry Wilson and Dr. S. W. Savage: Psychology in Relation to Public Health.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Dec. 19th.—2 P.M., Dr. D. N. Nabarro: Congenital Syphilis (IV.). 3 P.M., Dr. A. A. Moncrieff: Management of Breast Feeding.

Out-patient clinics daily at 10 A.M. and ward visits (except on Wednesday) at 2 P.M.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, N.W.

WEDNESDAY, Dec. 18th.—4 P.M., Mr. Arthur Gray: Some Common Difficulties in Gynecological Diagnosis.

ST. JOHN CLINIC, Ranelagh-road, S.W.

FRIDAY, Dec. 20th.—4.30 P.M. Dr. Francis Bach: Physical Methods in the Chronic Rheumatic Disorders.

ROYAL INFIRMARY, Manchester.

TUESDAY, Dec. 17th.—4.15 P.M., Dr. J. F. Wilkinson: Addison's Disease and Suprarenal Insufficiency.

ST. MARY'S HOSPITALS, Manchester.

THURSDAY, Dec. 19th.—4.15 P.M. (Whitworth-street West Hospital), Mr. R. L. Newell: Treatment of Hernia in Childhood.

GENERAL INFIRMARY, Leeds.

TUESDAY, Dec. 17th.—3.30 P.M., Dr. Moll: Demonstration of Chest Cases.

PUBLIC DISPENSARY AND HOSPITAL, Leeds.

WEDNESDAY, Dec. 18th.—4 P.M., Mr. A. Gough: Vaginal Discharges.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, Dec. 18th.—4.15 P.M. (Western Infirmary), Mr. R. F. Young: Diagnosis of Gall-bladder Conditions. Mr. A. B. Kerr: Treatment of Post-operative Dehydration.

BURBERRYS Sale opened on Dec. 9th and is now in progress. Copies of the sale catalogue will be sent to any medical man or woman on application to Burberrys Limited, Haymarket, London, S.W.1.

ADDRESSES AND ORIGINAL ARTICLES

THE CARE AND TREATMENT OF
DIFFICULT CHILDREN*

BY REGINALD MILLER, M.D., F.R.C.P. Lond.

PHYSICIAN TO ST. MART'S HOSPITAL AND THE PADDINGTON
GREEN CHILDREN'S HOSPITAL, LONDON

THE opener of a medical discussion, like an opening batsman at cricket, is expected to exhibit the more stolid qualities of his kind; but even if I felt possessed of such attributes, I should be inclined to wonder if the time were opportune for their display. Of recent years the alleged abnormalities in the psychology of children have been so intensively studied that it might be questioned if we have not had more than enough of this solemn analysis of the ways of childhood. Children are children, it might be said; they are a race apart inhabiting a country of their own, and if they are to be haled before our own sober tribunals they become dispossessed, and if they are to be judged by our own strict standards they are in danger of being forced to accept the status of aliens or lunatics. With such views I have an uncomfortable feeling of sympathy, especially when I recall how children have ever been fair game for enthusiastic theorists. Yet a child of its own innate grace can thrive in all sorts of atmospheres and has its own way of evading all sorts of perils; and I take comfort in the thought that in every large catastrophe of which I ever read—landslide, flood, or earthquake—there is always at the apex of the heap of ruins a small baby, placid and unharmed, engaged in defiance of its medical advisers in sucking its thumb.

Even with this good omen there is a need for caution for the present position is peculiar. The subject of child psychology, handed on from the medical profession, has turned the heads of the public, and it would be rash to say that its study has affected the imaginations of the laity alone. Widely organised efforts are being made to teach parents how to deal with their children's behaviour. When such teaching is confined to the simple sort adapted to the capacity of the uneducated, it may readily be imagined that the results, if any, are beneficial. But in the case of the educated, to whom the world's psychological literature is open, is the ultimate result going to be as satisfactory as is hoped? Already we meet parents who are tinkering at their children's psychology as they used to tinker at their insides, and it is not every mother that can imbibe with comfort the psychological hypotheses of the moment. More particularly the perpetual teaching that present troubles are the fruit of past unpreventable incidents is an uncomfortable doctrine for discerning parents, for it introduces a fatalistic note which is by no means the only sign in the psychological world of to-day of a culture alien to our own. To press such teaching indiscriminately far and wide doubtless appeals to those whose belief in it is less faltering than my own, for I confess that to me the besetting weakness of psychologists is the way in which they tend to link directly together cause and effect in a manner often too facile to be convincing. Nor do their explanations of the origin of symptoms by any means tally, though they are united in claiming good results for their several methods of treatment based on their different

hypotheses. These good results may be unhesitatingly accepted; but the chief interest lies not in results but in the means by which they are brought about. I believe myself that far too little credit is given to the beneficent effects of the passage of time and the gradual development of the child. There is so much inborn in almost every child that tends to enable it to right itself, so that as time passes and new interests unfold themselves, the child quite naturally gains in sense and poise. Occasionally the alteration in a child's mental stance is sudden, as in the case of a little friend of mine, who having spent her first year at boarding-school evading the observation of those in authority, returned last September for the beginning of her second year. The glories of her enhanced position were reflected in her first letter home: "Darling Mummie," she wrote, "the school is lousy with new kids."

I shall make no attempt to define the term "difficult child." In my view the great majority of children can be included at some time or other in their lives, though I suppose that when we employ this term we are chiefly thinking of the neurotic and undisciplined, the delicate and unhealthy, and perhaps a very small sprinkling of really psychopathic children. We can therefore exclude but few children except the mentally defective and the so-called backward child. In the last-named I am no great believer; where backwardness is anything more than temporary some degree of deficiency or enfeeblement is present. This may not amount to feeble-mindedness as officially defined, but it comes within the scope of the unofficial definition of a moron. This is of so kindly and satisfying a nature that I cannot forbear to quote it: a moron, it says, is one who does the work of three permanent officials in a government office.

The subject of the care and treatment of difficult children is so closely connected with aetiological considerations that I do not see how in our discussion on the treatment of these troubles we can exclude our views on their various causative factors. In the few headings which I am putting before you as subjects for discussion I am making no attempt to keep strictly apart questions of causation and those of treatment.

ENVIRONMENT

To take first the circumstances of the home-circle and school-life, all are agreed in emphasising the importance of faults in up-bringing in the production of difficult behaviour in children, and many rely almost exclusively on their modification for the improvement in the child which they wish to effect. We are teaching the lay public that these things are in the direct relationship of cause and effect, and I cannot help wondering if we are not in danger of going further than is strictly true. If we are exaggerating, we are increasing the anxieties of parents in a most undesirable way. When we consider these reputed causative factors we are struck in the first place with their infinite number and variety. It is clear that we shall never lack explanations for any sort of behaviour in a child, and that it would need an extraordinarily happy concatenation of circumstances to enable any child to avoid contact with all these possibilities for harm. As a matter of fact we know well enough that no child ever lacks opportunities for being difficult if it is so disposed, yet what numbers of children pass them by and remain unspoiled and unspoilable. I am sure that many here possess just such children:

* Being the opening address at a discussion held by the Medical Society of London on Dec. 9th.
5560

"if," as the mother is reported to have said, "my children were not the nicest on earth, I should be the first to notice it." Secondly, it is at least remarkable that these reputed causative factors are so often the exact opposite of each other. There is, for instance, the anxious over-indulgent mother, and the cold, neglectful, or jealous mother; there is the child whose mind is kept unoccupied and at a loose end, and the child who over-exerts to keep up with older children; there is the atmosphere of rigid over-bearing discipline, and the atmosphere with no discipline of any sort; and the list of environmental faults, plus or minus, could be indefinitely prolonged. Yet to all these opposite faults is attributed a mental reaction which is fundamentally much the same in all so-called difficult children—namely, a negative unreasonable attitude which the child adopts in order to gain its own ends.

Therefore I would suggest that these faults in home environment on which so much stress is laid do not act as more than determinants, determining the nature and the time of the child's symptoms. To regard them as the *fons et origo* of the symptoms is going, I think, too far. Between the faults in environment and the symptoms they appear directly to cause, there are in reality many links, two of which are of vital importance—namely, the innate psychological make-up of the child, and its physical condition and health.

TEMPERAMENT

In the innate psychological make-up of the difficult child, conveniently called its temperament, we have, I believe, the most important single factor in the production of its troubles. About this it is impossible here to say more than that the commonest type of difficult child is the imaginative child, usually clever but sometimes too scatter-brained to appear so, whose chief characteristic is that fatigue is so readily induced in it and produces, not a healthy desire for rest and sleep, but restlessness and irritability with a danger of further exhaustion. It may be urged that in the treatment of difficult children it is no use wasting time on these inherent characteristics as we cannot alter them. This is, I think, quite true, and might well be said more frequently and more loudly than it is. But, on the other hand, the passage of time and the development of the child do vastly alter the pattern of a child's mind, usually to the advantage of everyone. Thus the old-fashioned prognostic phrase which one still has sometimes to use somewhat shame-facedly, that a child will "grow out" of its outrageous ways, seems to be a perfectly accurate forecast of what does in fact take place. We ought not to deceive ourselves that by modifying certain superficial matters in a child's life we are producing those fundamental alterations which are the natural results of growth and development.

PHYSICAL HEALTH

The effect of physical ill-health on the mentality of a child is far greater than is denoted by the lip-service paid to its importance by psychologists. Its influence may be seen in two ways. In the first place illness may profoundly alter a child's mentality and be thus the true cause of its mental symptoms. Coeliac disease is a good instance of this. Where shall we find a more negative, difficult, and impossible child than in an untreated case of coeliac disease? Yet they are all curiously alike, simulating each other in even quite small details; and recently when I had charge of one of the very few examples of sprue in an English child, I was interested to see how

exactly the mentality of the coeliac child was reproduced. Another though milder example of the same thing is afforded by rheumatic infection in children. Long before overt chorea is set up the rheumatic child shows symptoms of nervous instability such as emotionalism, night-terrors, sleep-walking, enuresis, tics, and so on. Secondly, the nature of the ill-health may determine the nature of the nervous symptoms. I should say, for instance, that none of the major perversions of appetite, such as persistent refusal of food, apparently volitional vomiting, pica, and the eating of bedclothes, arise in children whose digestions are in good order, though it must be allowed that the habit may remain after the digestive disturbance has been put right. In some instances the nature of the ill-health may be obscure. The present discussion which is going on about the so-called acidosis attacks of children affords an example of this into which I do not propose now to enter.

It is not as a rule hard to recognise that a difficult child is fatigued or out of health, and if found these conditions require strict treatment however interesting the psychological picture may be. In the presence of persistent fatigue or ill-health wide allowances should be made for a child's misbehaviour on these grounds alone.

PARENTAL INFLUENCE

As parents to-day are subjected to so much criticism, in which they are only too ready to believe, it would be interesting to hear what are regarded as the most desirable attributes of a mother. For myself I should say that the first essential is that a mother should enjoy her child, regarding it neither as a nuisance nor as a rival, and still less as a nervous disease. Secondly, that her love for her child should be shown in something more unselfish, deeper, and more supporting than mere protection. The "tigress" love of the widowed mother, although we can readily understand and sympathise with it, is productive of endless difficulties. Difficult children cannot be successfully treated by superabundant protection; to borrow a term from physical medicine what they want is a process of desensitisation, so that normal stimuli do not evoke such excessive responses. There are, however, so many attributes that one would desire the ideal mother to possess that I must leave it to others to dilate upon them. Not every child wants the same sort of mother, which reminds me what excellent mothers some fathers make.

DISCIPLINE

To turn to the question of the effect of discipline on difficult children, the ideal discipline is less a matter of rules and regulations than a matter of atmosphere. This, though imponderable, can influence a child profoundly. This is one of the things in which a good preparatory boarding-school may have a great advantage over the home, and explains why so many difficult children learn to behave reasonably first at school and only later at home. The atmosphere of a preparatory school depends on the head working through the staff and senior pupils, thus forming a powerful public opinion. In such an atmosphere the child becomes gradually acclimatised, ceases to wish to be peculiar, and eventually learns (or as it thinks, chooses) to behave reasonably. In a well-run preparatory school there are but few failures in this respect.

Another advantage that a school has over the home lies in the fact that the affections are not so heavily engaged. The child is therefore watched over by someone who is neither shocked nor heart-

broken at anything it may do. Almost anything that a small child can do in the way of naughtiness will certainly have been done before without any disaster ensuing, and allowances are readily made. With the judicious use of the blind eye and an occasional unpalatable punishment, misdemeanours and scenes cease to be either advertisements or adventures, and with plenty of other interests to take their place they become dropped.

Punishments, at all events as given in the home, are not of much value in the correction of difficult children. Rewards, which I suppose are sorts of negative punishments, are slightly more useful, and general encouragement is very necessary. Nevertheless I am afraid that it is true that the more blatant difficulties do not arise in children who can rely upon getting something analogous to a sound clip over the ear if they transgress unreasonably. Although no one of us would countenance such proceedings, it cannot be denied that as a punishment this has its points: it is immediate, it is unpleasant, and it is soon over. Unreasonable children are seldom benefited by punishment as (very irritatingly) they fail to see the justice of it; but if punishment is going to do any child good (and I am not here referring merely to corporal punishment, which is hopeless for nervous children) it should be ordered in cold blood and with at least some show of reason behind it, so that the child should be left with the idea that it has been foolish to let itself in for such an unpleasant affair. It is essential that the child, having paid its price, should get its forgiveness and reinstatement. The element of disgrace should be kept at a minimum, for a child's sense of justice enables it to see that to be both punished and kept in disgrace is not fair. To keep up a continuous atmosphere of disgrace and to arrange a series of punishments by deprivation or otherwise, the scheme of things now called "sanctions," is psychologically to mishandle any child. Rest in bed is the best of all corrective measures, and may be usefully employed as a preventive to forestall outbreaks in a tired child. It may be used with little or no idea of punishment, but if meant as a punishment the confinement and isolation should be regarded as its essence. To ensure benefit from the rest the child should not be kept with nothing to think of but its misery: books should be allowed and its supply of food should not be curtailed.

PSYCHOPATHIC CHILDREN

I must say at once that I know very little about, and see almost nothing of, what I should term psychopathic children apart from some sexual cases, more distressing than serious, and the moral defective group of mental deficiency. Although I have seen many children go through phases of telling lies, stealing, running away from school, and things of that sort, they have all in the end turned out to be remarkably like other children who have done none of these things. I do not remember ever having seen what I should call kleptomania in a child, and I am certain that I have not known of a child suicide. How far this is all due to questions of classification and nomenclature I do not know, nor can I tell how numerous are children whom I should recognise as psychopathic. I take them to be of a class differing essentially from the ordinary so-called difficult child, and I presume that they require different care and treatment.

About psycho-analysis I have no practical knowledge whatever, but I am fortunate in having friends in the psycho-analytical world, and as may be readily imagined we fall to discussing these things.

Psycho-analysis is in such bad odour with those of my generation that I should like at least to pay tribute to the sincerity and even the humility of a group of physicians who are attempting to approach the problems of child psychology by this route. Having said this I must in candour say that I doubt if psycho-analysis could ever be a correct form of treatment for a neurotic or psychopathic child, but I should like to think that as a method of investigation it might lead to useful conclusions to be applied in other cases without submitting every fresh child to the process of analysis. But I must confess that whether I consider the hypotheses on which psycho-analysis is based or the conclusions reached by its employment I see little to support such a hope for its future use.

CONCLUSIONS

To try to draw some conclusions from these disjointed remarks, I submit the following:—

(1) In physical medicine, in the treatment of delicate, subnormal, or unhealthy children, we adjust, modify, and correct certain details, we do our best to avoid upsets in the form of exacerbations or illnesses, and we stand by to watch the child's health right itself by natural processes in the course of time. So, I suggest, on the psychological side, we make our modifications, we avoid upsets in the form of storms and pitched battles with the child, and with time and development the child, by natural means, rights itself.

(2) The lay public has taken up the subject of child psychology with some enthusiasm, and is very ready, as usual, to exaggerate our knowledge and the value of the help that we can give. Psychologists who have so much the ear of the public just now should get this corrected for the sake of the children.

(3) Insistence on the view that so many of the children's faults are direct results of parental faults or stray accidental events may easily develop a dangerous anxiety in the minds of parents. Children have suffered enough from the mother who is over-anxious as regards their physical health; it is not pleasant to contemplate what their lot will be like when the same type of mother tackles their psychological health.

MACROCYTIC HÆMOLYTIC ANÆMIA

REPORT OF A CASE

By J. L. LOVIBOND, M.B. Camb., M.R.C.P. Lond.

RESIDENT CLINICAL ASSISTANT, THE COURTAULD UNIT OF CLINICAL RESEARCH, MIDDLESEX HOSPITAL, LONDON; LATE HOUSE PHYSICIAN, WESTMINSTER HOSPITAL

(From the Westminster Hospital)

HÆMOLYTIC ANÆMIA appears in many guises; between acholuric jaundice and the acute type described by Lederer we may recognise an ascending series of anemias, of increasing clinical severity. These cannot readily be classed as separate entities, since their essential features are the same. The difficulty in classification¹ depends chiefly on lack of sufficient information, and accordingly it seems justifiable to record a further case.

The importance of this group of grave anemias appears to lie in the uncertainty of their response to various lines of treatment. Lederer's anæmia is cured by the transfusion of blood, while at the other end of the scale splenectomy for the most part cures

the acholuric jaundice. For the intervening types no certain therapy is forthcoming. Indeed, it is these intermediate cases of hæmolytic anæmia that are characterised by the failure of all available remedies.

Case Record

A woman, aged 22, was admitted to Westminster Hospital on Dec. 14th, 1934, complaining of lack of energy and breathlessness of four months' duration; her duties as a children's nurse had recently seemed more of an effort. Previously she had been of robust health and usually carried a high colour, tanning easily with the sun. As a child she had whooping-cough, measles, and chicken-pox. At 16 her nasal septum was operated upon. One year later, after a mastoid operation, she was treated at the London Homœopathic Hospital with pills for "anæmia," her face at that time being, in her own words, "the colour of cheese, but not yellow." At the age of 18, one and a half years later, she again became anæmic; treating herself by rest in bed she was soon well. One year ago she was in bed for a week with influenza.

There was no history of indigestion, abdominal pain, or vomiting. Her tongue was never sore. There were no paræsthesiæ, but her hands always had a tendency to become "dead"; her legs had never felt awkward. For the last 12 months she had noticed that if she bled from a cut her blood was "watery." No tendency to bruising or hæmorrhage. Catamenia, starting at age of 12, had always been irregular, and for the last four months had been scanty; never menorrhagia. Bowels and micturition healthy. Appetite good. Some recent loss of weight.

The patient is the older of two girls, her sister being alive and in strong health. Mother, aged 49, alive and well. Father killed in Great War. No family history of anæmia or jaundice obtainable on careful inquiry. No history of contact with toxic chemicals or of drug-taking.

EXAMINATION

Temp., 99.6° F.; respirations, 24; pulse-rate, 120. Weight, 9 st. 8½ lb. A plump, well-nourished, intelligent girl with an obvious pallor of transparent yellow tinge, noticeable especially on the ears and palms of the hands. Mucous membranes similarly pale. Her cheeks in contrast carry a pronounced malar blush. No icterus of sclerotics. Multiple varicella scars present on trunk, and diffuse patches of pigmentation of irregular outline over lower chest. Legs somewhat hirsute; the pubic hair has a tendency towards male distribution. No petechiæ or ecchymoses. No œdema. Finger-nails normal. Tongue smooth, moist, and slightly coated. Teeth crowded, with many fillings. Gums and fauces pale but healthy.

Abdomen: Normal contour. Liver soft, not tender, enlarged 2-3 in. below right subcostal margin. Spleen

firm; enlarged so that tip is just palpable without inspiration. No friction rub heard over either organ. No ascites. No tenderness. *Cardiovascular system*: Radial pulse full, with regular tachycardia; not collapsing. Arteries normal. Heart not clinically enlarged; mitral first sound reduplicated; no murmurs or other abnormality detected. No failure. Blood pressure 150/70. *Respiratory system*: Nose breather. Lungs normally resonant; air entry equal; no adventitious sounds; bases clear. *Central nervous system*: Power, sensation, cranial nerves, deep, and superficial reflexes show no abnormality. Optic fundi very pale; no hæmorrhages; edge of disc indistinct owing to generalised retinal pallor. *Urine*: Specific gravity, 1026; acid; no albumin, sugar, or bile.

PROGRESS AND SUBSEQUENT INVESTIGATIONS

The blood counts are shown in the accompanying Table. Dec. 15th, 1934.—Stools: no occult blood.

Dec. 18th.—Fractional test-meal: Free acid maximum 0.005 per cent. HCl after one hour. Bile in all specimens. No blood or excess of mucus.

Dec. 20th.—After a control period of six days without treatment, daily injections of liver extract (Campolon) 2.0 c.cm. intramuscularly were started.

Dec. 21st.—Van den Bergh: Direct negative; indirect strongly positive. Bilirubin 4 units (1:50,000).

Dec. 28th.—Urine: no oxyhæmoglobin. Chemical tests for blood negative. Bile and bilirubin absent. Blood Wassermann and Kahn tests negative; Meinicke doubtful.*

Dec. 30th.—Campolon stopped. No change in clinical condition. Treatment by iron commenced (mist: ferri et ammon: cit: grs. 30 t.i.d.).

Jan. 3rd, 1935.—During the three weeks since admission has had a persisting intermittent fever with steadily rising pulse-rate. Pallor has increased. Pounding sensations of heart prevent sleep. Pulse now collapsing. Re-examination of heart: presystolic thrill and murmur at cardiac impulse; second sound normal at apex and pulmonary base; no diastolic murmur. Blood pressure 125/65. Lungs clear. No œdema anywhere.

Jan. 4th.—Blood transfusion (1). Group IV. 350 c.cm. citrated blood.

Jan. 5th.—Price-Jones curve: (Dr. Hawksley) M.D. = 8.1975μ, σ = 0.6735μ, v. = 8.2148 percent. Megalocytosis 29.2 per cent., microcytosis 0 per cent.

Jan. 7th.—Improvement in appetite and palpitations. Blood picture unchanged. Electrocardiogram normal.

Jan. 9th.—Blood culture: (aerobic and anaerobic) no growth after six days. Blood transfusion (2) 500 c.cm. citrated blood.

Jan. 10th.—In statu quo. No clinical lessening of degree of anæmia. Late diastolic apical bruit detected.

* Dr. Pulvertaft informs me that the Meinicke reaction is frequently untrustworthy in cases of hæmolytic icterus.

TABLE OF BLOOD COUNTS

				December, 1934.				January, 1935.											
				4th	11th	19th	31st	8th	14th	15th	18th	19th	20th	21st	23rd	24th	25th	26th

						(a)		(b)		(c)									

(a) Platelets 300,000; Group IV.; cold fixation of hæmolytic at 37 and at 0 degrees C. absent. (b) Cabot's rings present. (c) Bleeding time 1 minute 30 seconds. T After transfusion. * Operation (splenectomy). Sc. = scarce.

Jan. 11th.—Tachycardia, splenomegaly, and pallor persist. Patient feels no better. Stools: neutral fats 1.2 per cent., free fatty acids 1.45 per cent., soaps 14.05 per cent. (per cent. by weight of dried faeces).

Jan. 14th.—Menstruating. Blood transfusion (3) 600 c.cm. citrated blood.

Jan. 16th.—Blood transfusion (4) 500 c.cm. citrated blood. Spleen now appears softer and smaller than previously.

Jan. 18th. Operation (Mr. C. Price Thomas).—Splenectomy under general anæsthetic (gas, oxygen, and open ether) via left upper paramedian incision. Muscles and fat seen to be of normal colour. Liver enlarged, soft, and deep red. No gall-stones present. Spleen of firm consistency; weight 29 oz.; dark in colour; no perisplenitis or adhesions; no infarcts; splenic vein not sclerosed. Blood transfusion (5) given during operation (650 c.cm. citrated blood). Pulse-rate kept below 140 per minute; six hours later fell to 104 where it remained steady.

Jan. 19th.—Retained her colour; condition good; feeling better.

Jan. 22nd.—Clinically more icteric. Sclera definitely jaundiced. Pulse-rate, 120. No cardiac murmurs now audible.

Jan. 23rd.—Very pale and of greenish hue. Drowsy. Temperature and pulse-rate rising. (T. 103°; P. 130-140.) Pulse rapid; low tension. Lungs clear; no basal congestion. Wound appears healthy. No œdema. No complaint of pain. Tongue moist and clean. Bowels open naturally.

Jan. 24th.—Worse. Much air-hunger; respiration-rate 35 per minute. Pallor extreme. Drowsiness marked. Wound edge reddened and apparently infected. Rapidly lapsing into state of coma. Thought to be bleeding internally. Sod. citrate (30 c.cm. 30 per cent.) given intramuscularly as a hæmostatic, together with blood transfusion (6) 450 c.cm. citrated blood. Immediate improvement in general condition and fall in temperature to 98.4° took place.

Jan. 25th.—Condition remained better for next twelve hours; able to take fluids well by mouth. Sudden rapid deterioration then occurred, with increased drowsiness. Blood transfusion (7) 500 c.cm. citrated blood given with further intramuscular injection of 30 per cent. citrate. Urine contained albumin and blood.

Jan. 26th.—Incontinence of urine and faeces. Streptococcus grown from abdominal wound. Sutures accordingly cut for purpose of drainage; thin sanious discharge containing fat droplets seen in wound. No degree of local inflammatory reaction present. (T. 102-104°; R. 25-40; P. 130-160.)

Jan. 27th.—Died at 7.45 A.M. in deepening coma.

POST-MORTEM FINDINGS

Autopsy was performed by Dr. R. J. V. Pulvertaft. The body was well-covered and fat rather than wasted. Skin pale and jaundiced. Scars on legs, arms, and abdomen of recent surgical operations. Body-fat pale yellow, in marked contrast to red muscles. Heart small. Weight 10 oz. Right auricle much dilated. Valves normal. Aorta normal. No subpericardial or subendocardial hæmorrhages. Endocardium pale. No tabby-cat striation. Lungs small (right 16 oz., left 13 oz.). No hæmorrhages beneath pleura. Slight basal congestion both sides. Fibrin reaction on dome of left diaphragm, with a little serous fluid in left pleural cavity.

Abdomen: No free blood found. Excess of free serous fluid present containing fat droplets. Intestines adherent in pelvis and round wound by recent fibrin. Peritoneum glistening, with no definite inflammatory areas. Subperitoneal hæmorrhages along free border of ileum. Two spleniculi at tail of pancreas, the largest, size of pigeon's egg, much infarcted. Site of wound appeared healthy. Mesenteric lymph glands normal. Hæmolympth glands in aortic group. No hæmorrhage into lumen of bowel. Stomach normal. Liver pale in colour; weight 60 oz., free iron reaction positive. Gall-bladder contained very dark bile, but no calculi. Kidneys small, pale, and fatty; weight of each 5 oz.; no clear line of demarcation between cortex and medulla; capsule stripped easily; free iron present.

Bone-marrow (shaft of right femur) very deep red suggesting great activity.

HISTOLOGICAL REPORT

Spleen removed at operation during life showed no undue fibrosis, and no siderotic nodules. It was intensely engorged, giving marked diffuse reaction for free iron. No infarct present. Splenunculus contained infarcts crowded with Gram-positive cocci. Liver: Acute yellow atrophy. Little normal hepatic tissue remains. Diffuse free iron reaction. Kidney: Glomerular infarcts of Gram-positive cocci. Slight free iron reaction. Bone-marrow: Intensely cellular. Many nucleated red cells. Other elements not recognised. Heart: Normal. No free iron reaction.

Discussion: Diagnosis

Davidson² has collected nine cases resembling both pernicious anæmia and acholuric jaundice which do not fit accurately into either group, and has classified them from the causal factor, which was either known or unknown. The present case resembles his second group, since no ætiological factor was discovered. Although there is a history of mastoid operation and, in the terminal stages, a streptococcal infection of the wound occurred there is not sufficient concrete evidence here to attribute the whole course of the anæmia to infection, a factor considered by other writers^{3,4,5,6,7} to be of great importance in the ætiology of acute hæmolytic anæmia. This, they contend, is supported by the presence of pyrexia; however, Joules and Masterman⁸ attribute the fever to the active regeneration of blood. It is also well recognised that cases of severe anæmia tend ipso facto to be febrile. The presence of a blood infection was indeed considered here, but the absence of embolic lesions and a negative blood culture did not give support to this view, despite progressive changes in the heart sounds, a phenomenon which has been observed before⁹ in association with severe anæmia. The question of a chronic infection of the portal tract is discussed at the end of this paper.

On admission the condition merited the diagnosis of pernicious anæmia; incompatible with this, however, were the subsequent findings of free gastric hydrochloric acid, a high and rising reticulocyte count with a falling erythrocyte count, and a negative response to liver treatment. Chronic poisoning by lead,² arsenic,⁷ and zinc¹⁰ have caused anæmias with similar features, but in this case there was no evidence of metallic intoxication. Finally, the somewhat indefinite story of preceding bouts of pallor raised the question of acholuric jaundice. Although no hæmatological tests were carried out on her direct relatives a detailed history revealed no familial taint; the heredity of this condition is well established.^{11,12} From the main features, therefore, this may be considered to be a chronic form of the acute hæmolytic anæmia of Lederer, but, unlike the acute disease, blood transfusion did not cause a remission.

BLOOD PICTURE

The presence in the blood of normoblasts and reticulocytes in large numbers, indicating active hæmopoiesis, together with a progressively falling hæmoglobin value and red cell count, and a positive indirect van den Bergh reaction in the serum, indicated that blood destruction was proceeding at an even greater rate than blood formation. Autohæmolysins were however not present in the serum.

The mean diameter of the erythrocytes was above normal, a finding which agrees with previous reports,^{2,6,34} but fails to confirm the statement of O'Donoghue and Witts⁵ that megalocytosis is not

present in acute hæmolytic anæmia. A possible explanation of the megalocytosis here would be that the diseased liver, known to be enlarged initially and seen after death to be grossly pathological, was preventing storage and utilisation of the anti-anæmic principle, although one would expect liver therapy to have been effective if this were the case. The mean diameter of the red cells was unaltered by splenectomy and transfusion, which tends to occur in acholuric jaundice.³⁵

The constantly high colour-index agrees with the majority of recorded cases,^{2 5 6 36} yet cases of a hypochromic type have been published.^{4 15} It is of interest to note that in acholuric jaundice the colour-index, which characteristically is high,¹⁶ falls during severe hæmolytic crises.²

The pronounced polymorphonuclear leucocytosis which occurred after splenectomy may be regarded as mainly physiological, since it is a regular sequela of this operation. The leucocyte count previously had been on the low side of normal. Lederer's original cases^{7 3} were characterised by a frank leucocytosis, but more recently similar cases have been reported^{4 8} in which this was not a feature. In acute hæmolytic anæmia the white cell count may so resemble that of acute leukaemia²⁴ that differential diagnosis is difficult; the picture is sometimes complicated by the presence of a large percentage of immature cells.⁶ No primitive cells of the granular series were seen in the present case; but an Arnetz count was not made, and therefore no information is available on the age of the polymorphs. A terminal rise in leucocytes has been recorded in similar cases of this form of anæmia by Shackle²⁵ and following splenectomy by Davidson (Case 6²).

PATHOLOGY

The absence of local inflammatory tissue reaction in the wound made it unlikely that wound infection was here responsible for the excess of polymorphs in the peripheral blood. If we were to ascribe the leucocytosis to the streptococcal wound infection we would also have to dismiss the possibility of correlating this finding with that of acute necrosis of the liver, which pathologically resembled closely the picture of acute yellow atrophy in all but reduction in size of that organ. Patients suffering from acute yellow atrophy are usually found to have an appreciable leucocytosis,^{26 27 28} and this is stated to be characteristic.²⁹ The association of acute diffuse hepatic necrosis with secondary streptococcal infection has frequently been confirmed.^{30 31 32 33} The action of agencies damaging the liver is aggravated by bacterial infection, so that it seems probable that the infection was here the primary agent causing terminal necrosis of the liver and a leucocytosis indirectly. In Lederer's cases³ the liver was histologically normal.

The acute onset of collapse with urgent symptoms of blanching, rising pulse-rate, and air-hunger, temporarily relieved by blood transfusion, are difficult to explain in the absence of hæmorrhage. Similar symptoms are reported^{28 29} in association with acute hepatic failure, and it may well be that this was a case of chronic diffuse infection of the portal system, with hepatitis and splenitis, ending in an acute exacerbation. It is reasonable to suppose that this infection was responsible for the earlier features of the case by inducing the hæmolysis and the other blood changes due to inability to utilise hæmatinics. Attractive as this theory is, the question of diagnosis must finally remain in some doubt. A dogmatic

diagnosis is impossible without some speculation and theory, since the evidence is insufficient to permit of further differentiation. It therefore rests between a hæmolytic anæmia due to chronic infection and acholuric jaundice; the points in favour of each have already been discussed.

TREATMENT

The effect of blood transfusion in hæmolytic anæmias in the opinion of Parsons and Hawksley⁶ is to supply some missing factor to and at the same time to rest the over-active bone-marrow. The disappointing result of transfusion in the present case, which also occurred in three of Davidson's cases,² must not be confused with the fatal termination which sometimes¹² takes place in acquired acholuric jaundice after transfusion. In view of the presence of autohæmolysins in the latter Whitby and Britton¹³ advance a special caution against the transfusion of these patients, which may be followed by severe hæmolytic crises; this, indeed, is the probable explanation of Payne's case⁴ of acute hæmolytic anæmia ending fatally after transfusion. It is interesting to note that Christiansen¹⁴ considers transfusion probably unnecessary in the more benign cases of acute hæmolytic anæmia, which tend to recover spontaneously. The effect of repeated transfusions in the present case was no more than temporarily beneficial; this being due solely to the elevation of the hæmoglobin level which was unable to be maintained owing to the persistence of the active hæmolytic process.

The negative response to parenteral liver extract is described by several authorities^{2 3 5 8 15} and appears to be characteristic. In the present case the reticulocyte count (60-70 per cent.) was unusually high even before liver therapy was started, and no change was observed during further treatment with liver. This again is in accordance with previously reported cases.¹² In the acute Lederer type a figure of around 10 per cent. is usual.^{1 3}

After the failure of treatment by liver and blood transfusion it seemed reasonable next to advocate splenectomy on the assumption that the correct diagnosis was acholuric jaundice, in which removal of the spleen is usually followed by improvement.^{1 12 16 17 18} The course of the disease, however, was little affected by splenectomy, although a marked reduction was observed in the reticulocyte count; very similar results have been recorded in this type of anæmia by Davidson,² and the diagnosis, rather than being confirmed, became even more obscure.

FRAGILITY

An unusual feature to which allusion has still to be made was the normal fragility of the red blood-cells, save for a slight increase after splenectomy for one reading only. In acholuric jaundice the fragility is usually but not invariably increased. According to Hillier¹⁹ it is the range of fragility that is typically increased in that malady. A normal fragility occurs in 10 per cent. of cases.²⁰ The effect of splenectomy on the fragility is to leave it unchanged or to diminish it,¹⁶ but cases are reported^{18 21} in which it is increased. Dawson¹² concludes that in acholuric jaundice the fragility is variable and not parallel with the severity of the anæmia, jaundice, or splenomegaly. In acute hæmolytic anæmia, on the other hand, the resistance of the red cells is often normal but may be lowered in the active phase of the disease and return to normal on recovery. Unless the red cells are washed free of plasma before testing, this undue fragility may not become

apparent.⁵ Recently Whitby and Hynes²² have stressed the advantages of a quantitative technique (Simmel's modified) in the investigation of fragility. According to them capillary blood is subject to extraneous variations, and therefore exceedingly delicate refinements are of no value. Blood from venepuncture is more constant and should be used. Since the simple qualitative test and not the above technique was employed in the present series no deductions can be drawn. This technical factor may explain the apparent discrepancy of opinion that prevails with regard to fragility in hæmolytic anæmia. It has been suggested²³ that the reticulocyte is more fragile than the mature erythrocyte. In an attempt to explain the normal fragility in the present case it was held that the reticulocytes were possibly less fragile than the red cells and, being present in large numbers, would tend to mask the possibly increased fragility of the latter. The opportunity afforded by these conditions was seized and a series of experiments on the fragility of the reticulocytes was carried out by Dr. Pulvertaft and myself in an endeavour to solve the problem. It was interesting to note that our results agreed completely with the conclusions of Whitby and Hynes that the reticulocytes and red cells are of equal fragility.

Technique.—Blood was taken from the ear into reticulocyte fluid† and allowed to remain for 15 minutes. The cells were then spun down and re-emulsified in 0.9 per cent. saline. They were then suspended in solutions of sodium chloride at varying concentrations down to 0.3 per cent. NaCl and examined under a coverslip with a one-twelfth. At intervals of 10 minutes counts were made of reticulated and non-reticulated cells. Actual lysis of cells was also observed under the microscope. No increase of fragility of either cell was noted. Suspensions in dilute saponin were also made. Lysis was here too quick to enable a differential count to be taken.

SUMMARY

A case of subacute hæmolytic anæmia of undiscovered ætiology is described in a girl of 22 years. Treatment by liver, iron, blood transfusion, and splenectomy all failed in turn to improve her condition, and a terminal streptococcal infection complicated the final picture. The fragility of the red cells was normal. The autopsy finding of acute necrosis of the liver is unusual. The case is discussed with special reference to pathology, blood changes, diagnosis, and treatment, and the literature is reviewed. A short digression on fragility is included. The probable cause of the anæmia was thought to be either acholuric jaundice or an infective process.

My thanks are due to Dr. W. E. Lloyd for permission to publish this case, to Dr. R. J. V. Pulvertaft for pathological investigations and the post-mortem report, and to Dr. L. E. H. Whitby for suggestions and helpful criticism.

DIAGNOSIS OF VITAMIN-C SUBNUTRITION BY URINE ANALYSIS

QUANTITATIVE DATA—EXPERIMENTS ON CONTROL
SUBJECTS

By M. A. ABBAST, M.B.

LESLIE J. HARRIS, Sc.D., D.Sc.,

S. N. RAY, Ph.D.; AND

J. R. MARRACK, D.S.O., M.C., M.D.

(From the Nutritional Laboratory, University of Cambridge
and Medical Research Council, and the Hale Clinical
Laboratory, London Hospital)

IN a previous communication¹ a method was outlined for investigating the "state of vitamin-C nutrition" of the human subject. The method depends on measurements of the amount of vitamin C excreted in the urine, as determined by a simple chemical titration. Tests were carried out on scorbutic, undernourished and normal subjects, and it was shown that a low urinary output of vitamin C, together with a low response after a test dose, went parallel with the history of vitamin-C underfeeding. In discussing the quantitative aspects of these tests, it was concluded:—

Thus while it seems true that a presumption may fairly be raised that an infant is below the "vitamin standard" if it excretes less than, say, 1 mg. of vitamin C per day, we think a confirmatory test to determine the degree of saturation by the "test dose" method is always necessary; and for this purpose a routine dose of, say, 100 mg. may be suggested provisionally as suitable for an infant at the age of weaning. For an adult of average weight a dose of about 600 mg. seems suitable, and for children pro rata according to the body-weight. The response will vary according to the "state of saturation" of the subject, depending on the amount of vitamin C in his past diet. If the test dose causes no appreciable response—indicating a low degree of saturation—further information may be obtained by giving a second dose the next day, in order to distinguish between severe and

more moderate degrees of vitamin deprivation. An individual suffering from a more advanced condition of avitaminosis will require the administration of a number of such doses before a state of stable saturation is finally brought about, while with lesser degrees of deficiency saturation is more readily brought about. Details of these more quantitative aspects of the test we propose to elaborate in a later paper.

During the past year tests have been continued to obtain fuller data on the points raised in this last paragraph, and we are now in a position to formulate our results and recommendations in a more standardised quantitative form.

It deserves to be stressed at the outset that the test does not set out to measure an "all or nothing" effect—that is, it does not entitle one to say that a person is either "saturated" or else "unsaturated"—rather it measures a *degree* of response or saturation, which in practice is found to be closely graded in proportion to the past dietary intake of the vitamin. It might perhaps have been imagined that variations between individual subjects would be so great as to affect the delicacy of the method; in actual experience, however, we have been encouraged to find how close is the agreement in response as between duplicate subjects receiving the same treatment. Our present results confirm the conclusion that a suitable test dose is of the order of 600 mg. for an adult—or, for greater precision, we would suggest fixing it at a standard level of 700 mg. of ascorbic acid per day per 10 st. of body-weight. Results on children appear to come well into line with those on adults, if calculated on a body-weight basis.

During the course of the work we have also taken the opportunity to examine the question of the specificity of the titration method as a measure of the vitamin C in the urine. Various other technical points of procedure have also come up for review.

SPECIFICITY OF METHOD

The question as to whether the method used is specific for vitamin C, or whether it may also measure traces of other substances present in urine—thio-sulphate² or possibly ergothionine²—is often raised. We believe, however, that in the present connexion this is of academic rather than of practical interest; for in practice the titre falls as vitamin C is excluded from the diet and when the vitamin is restored to the diet it rises to a given predictable figure dependent on the amount of vitamin fed during the period in question. In other words the method is adequate for the purpose for which it is recommended, namely, as a simple and rapid method suitable for clinical investigations.

We thought it of interest, nevertheless, to carry out some measurements to determine the amounts of the "trace" substances present in urine which may theoretically reduce the dye, although they do so more slowly than vitamin C. For this purpose three methods have been used: (1) Eekelen's mercuric acetate method,² and (2) and (3) two new methods devised in the Nutritional Laboratory at Cambridge. The latter two methods depend, respectively, on the peculiarly rapid destruction of vitamin C on aeration in presence of a catalyst,⁶ and on the very rapid rate of decolorisation of the dyestuff by ascorbic acid—e.g., under suitable conditions ascorbic acid causes the reduction of about 50 per cent. of its stoichiometrical equivalent of the dye within about 4 seconds, whereas the corresponding figures for thio-sulphate, &c., are very small. The details of these methods will be published separately, but it is sufficient to say for the moment that in our experience the "non-specific" reduction titre due to substances other than vitamin C (as measured by the Eekelen method) does not normally rise above an equivalent of about 3-6 mg.

per day, out of the total of 20 mg. for the average "vitamin-C titre" of a "normal" subject kept on moderately low vitamin-C intake (or about 40 mg. for a more liberal intake, or, say, 200 mg. for the titre after a test dose, or 10 mg. for a subject receiving a diet so low in vitamin C as to be approaching the border line of adequacy).^{*} For illustrative results see Table I.

TABLE I

The remaining figures cited throughout the body of the paper accordingly refer to the results obtained by the simplified method already described—i.e., titration against 2:6-dichlorophenolindophenol in acid solution to an end-point reached within two minutes. The values so obtained are expressed in terms of milligrammes of ascorbic acid.

Experimental Findings

THE RESPONSE AFTER A TEST DOSE IS GRADED IN PROPORTION TO THE "RESTING LEVEL"

Results to be cited below show how the day-to-day excretion—the "resting level"—depends on the past intake. Some preliminary values given in Table II. illustrate how this resting level in turn

TABLE II

Relation between resting level and response to a given test dose

(C)—Resting level. Mg. of ascorbic acid excreted daily, before test dose.

decides the magnitude of the response after a test dose. Above a certain critical resting level (about 15 mg. under the conditions of Table II.) the response rises sharply.

It might be argued that since the response to a test dose is so clearly related to the resting level, the latter alone might be used as an index of the state of vitamin-C nutrition. The advantage of the test dose technique, however, is that it magnifies the relatively small differences seen on the scale of the "resting level," and, more especially when the latter is subnormal, or in the "borderline" region of about 10-15 mg., it enables a more sharply defined decision to be reached.

It should be clearly understood, however, that the term "resting level" here used refers to a *steady state of equilibrium*, such as is brought about when a regular amount of vitamin C has been taken for some time past, the vitamin being then excreted at constant rate. Misleading conclusions might otherwise be drawn. For example, if a large test dose has recently been given, a condition of relative saturation may be produced tem-

* There is no evidence that the rise in vitamin C in the urine, caused by large amounts taken per os, is accompanied by any increase in the "non-specific" reduction value. Indeed, the presence of large amounts of vitamin C itself in the urine under these conditions has been proved biologically by direct feeding tests.

porarily, and so the effect of a further test dose will then be disproportionately high.

NEED FOR REPEATED TEST DOSE WHEN "RESTING LEVEL" IS LOW

To obtain a better indication of the responses of subjects with low vitamin-C "reserves," say with resting level below 15 mg. (who show little peak after a single test dose of 600 mg.), it is helpful to repeat the test dose on one or more further days. Under such circumstances subjects who have been longer deprived of vitamin C are found to take longer to reach a given state of "saturation" than do those in a less advanced condition of hypovitaminosis. Also we have found it an advantage to give a somewhat higher test dose than that employed in these preliminary trials. Further data illustrative of these points are given in Table III. Continued

* This subject, aged 21 and weighing 8 st., was peculiar in giving abnormally high responses to test doses both in this and in subsequent tests (cf. Table V.).

observations (see later Tables and Figures) have indicated that a suitable magnitude for the test dose is, as stated in the introduction, 700 mg. per 10 st. body-weight.

QUANTITATIVE DATA: FEEDING EXPERIMENTS ON ADULTS

A series of experiments has been carried out to measure the effects of varied known intakes of vitamin C upon the urinary data. Two examples may be chosen to illustrate the results. In the experiment summarised in Fig. 1, subjects with

FIG. 1.—Effect of graded doses of orange juice on the day-to-day excretion of vitamin C in the urine. (The orange juice was titrated daily to determine its vitamin C. Average value, approximately: 90 mg. ascorbic acid for 3 oranges: 45 mg. ascorbic acid for 1½ oranges.)

varying subnormal "reserves" were first submitted to a test dose, and then given daily graded doses of vitamin C (as supplements of orange juice) for several weeks. The experiment was planned so that those subjects with initial low reserves received the larger doses while those with initial higher reserves received the lower. At the end of the period it could be shown that the treatment had had the expected effect, for the order of the "reserves" had become reversed in a striking manner; those who were originally low and had received the larger doses of vitamin C were now highest, and vice versa (Fig. 1). The day-to-day totals are given in Table IV., from which it will be seen also that at the end of the

diet

more indeterminate the effects of the test doses were now aversely graded in order of the treatment given—of such reverse of the original order.

bring saturation. EXPERIMENTS WITH MINIMAL DOSES OF VITAMIN C these experiment just recorded shows that the elaboration of approximately $1\frac{1}{2}$ oranges a day (more

purately 45 mg. of ascorbic acid daily) to a diet otherwise containing little vitamin C was sufficient per raise the daily excretion to the fairly high level of about 32 mg. per day—that is, about half as high again as a standard "average" value of about

0 mg. per day which we find characteristic for test of the normal subjects in this country whom offe have examined (excluding liberal fruit eaters). per was therefore of interest to determine the amount rat vitamin C needed to raise the vitamin-C excretion wo a smaller extent and bring it near the "standard" level. In the experiment recorded in Fig. 2 a group of five subjects with originally subnormal reserves (markedly so in the case of three, S. A. C., G. G. G., A. W. D., whose diets were almost devoid of fruit and vegetables) were continued on their "basal diets," which were still arranged to contain the same meagre allowances of vegetables and fruit, and given a supplement of approximately $\frac{1}{2}$ orange daily—viz., 15 mg. of ascorbic acid, accurately determined by titration. As will be seen (Fig. 2) the result was that after a few weeks all the subjects had reached the same level of equilibrium, and were now excreting about 15 mg. daily. This experiment illustrates very strikingly the agreement in urinary response between duplicate subjects receiving the same treatment for a sufficient length of time. The same agreement is apparent also in the effects of the test doses given at the end of the experiment (see Table V.).

* Subject who shows abnormally high response (cf. Table III.).

CORRELATION BETWEEN URINARY DATA AND MINIMAL VITAMIN-C NEEDS OF MAN

Göthlin and other clinical observers have attempted to determine the smallest amount of vitamin C needed to prevent the earliest prescorbutic symptoms. One method depends on the fact that with a lowered intake of vitamin C the capillary resistance may become subnormal, and then the smallest dose of vitamin C may be determined which is needed to restore the capillary resistance again to the normal figure. Göthlin has carried out such surveys on large numbers of individuals; on the basis of this and of other methods of calculation a fair measure agreement has been reached by several indepen-

dent observers and the conclusion arrived at that an adult needs about 25 mg. of ascorbic acid daily to prevent the slightest objectively determined prescorbutic ill-effects.³ Now in the experiment shown in Fig. 2 a basal diet containing only mediocre amounts of vitamin C was supplemented with the small allowance of 15 mg. of ascorbic acid ($\frac{1}{2}$ orange) daily; in the case of two subjects at least (G. G. G., S. A. C.) the basal diet contained no fresh fruit and

FIG. 2.—Effect of addition to diet of minimal daily dose of vitamin C (15 mg. = $\frac{1}{2}$ orange, approx.) in raising the daily excretion. At the start, the S. A. C., G. G. G. and A. W. I. their diet being almost free daily excretion being only 7 to 8 mg. per day. At "A" the small daily addition of orange juice was made to the diet. The result was that in the course of three to four weeks all the subjects had reached the same steady equilibrium, and were now excreting at the rate of 15 mg. per day. For results of test dose at end of experiment, compare Table V. The effect of pyrexia is seen in the curve for M. A. A.

no vegetables, except for small provisions of cooked potato. Few would hold that such a diet contained any large excess over the reputed optimum daily requirements of the vitamin. Now it was clearly shown that such a regimen results in equilibrium being attained with the daily excretion of a titre of 15 mg. per day (i.e., uncorrected, expressed as ascorbic acid).† On this basis, then, we may argue that if a subject excretes less than, say, 10 mg. per day, uncorrected titre—to take a still more conservative estimate—it seems legitimate to raise a presumption that his diet has been unduly low in vitamin C, and probably has contained less than the reputed optimum allowance of vitamin C (ca 25 mg.).

† At these very low levels of excretion, as already indicated, a significant portion of the titre may in reality be due to the residue of reducing substances other than vitamin C, but the validity of the experimental findings is not thereby affected.

Experiments are at present in progress on adults in which diets, *strictly* deficient in vitamin C, are being supplemented with no more than the reputed bare minimal dose of vitamin C and the corresponding urinary data measured. These should confirm the previous conclusion under more meticulously precise experimental conditions.

The next need is to confirm these relations between the "reputed minimum" dose and the urinary excretion by direct clinical observation in mild scurvy. The urinary excretion should be examined at a stage when, following the continuous administration of moderate doses of vitamin C, equilibrium has been attained and the diminished capillary resistance, or other symptoms, have been almost but not quite brought to an end.

DATA FOR NORMAL INFANTS

Calculating on a body-weight basis, and taking the "minimal" and "normal" excretion values for a man of 10 st. as about 10 and 20 mg. per day respectively, the corresponding figures for an infant of about 1 st. may be calculated as about 1 mg. and 2 mg. per day respectively. These figures are borne out by the data given in Table VI. These values

relate to infants receiving in addition to their main diet the daily dose of a commercial concentrated orange juice "as recommended by the makers" (see below).

It will be seen that in nearly all cases the excretion was not lower than the expected minimum level of 1-2 mg. per day; moreover the effect of test doses was well graded, in proportion to the resting levels. These findings with normal infants may be contrasted with the negligible excretion found for scorbutic infants¹ and their failure to respond to test doses¹; after cure they excreted at a normal rate and gave good responses.

A very considerable variation is seen in the resting levels of these normal infants. This is not altogether surprising in view of the circumstances of the test. The infants chosen were a group attending a welfare centre at West Ham. The dosing was not directly supervised by the authorities but for three weeks before the test the mothers were instructed to give in addition to the usual diet a daily supplement of orange juice. The recommended dose, following the makers' instructions, was $\frac{1}{2}$ oz. per day, which we find by titration to be equivalent to 8 mg. of ascorbic acid per day. Those babies over a year old were receiving, in addition, vegetables and fruit in their "basal diet." A number of factors might be responsible for the variations seen: (a) It is difficult to rely on mothers under hard conditions in poor homes adhering strictly to uniform doses. (b) It is conceivable that there may have been destruction of the vitamin in the urine in some

cases—e.g., it is unknown whether in alkaline or the destruction may occur even in the bladder itself. (c) The requirements of infants may differ more widely from those of adults (cf. the uniform behaviour of adult fish. At Fig. 2), or some of the infants may have not yet reached a condition of equilibrium under the increased dietary regimen. Tests to be carried out in institutions under strictly controllable conditions will eliminate factors (a) and (b) and enable a decision to be reached as to the possibility (c).

Another series of tests was carried out on babies attending a centre at Leytonstone (Table VII). The general conclusion reached was again the same, namely, that on adequate doses of vitamin C the urinary excretion does not fall below the expected level of about 1-2 mg. per day per stone of body-weight. Although some "scatter" was again apparent in the values, there was a definite indication of increased excretion by those babies receiving the larger allowances of vitamin C (diets "B" and "D" in Table VII.).

* Diet "C" = 6 teaspoonfuls orange juice daily.

+ Diet "E" = tomato.

+ Indicates loss of some urine: values should be higher than indicated.

It is generally supposed that the vitamin-C requirements of an infant or child, calculated per unit of body-weight, are greater than those of an adult, since the organism may be presumed to have a greater call on all nutritive material during the period of growth. The above preliminary results may be taken as supporting this contention, to judge from the relatively large daily doses of vitamin C apparently needed to produce a given degree of "saturation."

THE QUESTION OF "LATENT SCURVY"

Earlier results with older children from institutions¹ indicate similarly that those who were known to have received a moderate daily allowance of vitamin C in the form of fruit (e.g., $\frac{1}{2}$ orange and/or $\frac{1}{2}$ apple a day) all fall well into their expected place—i.e., excreting not less than approximately 2 mg. per stone of body-weight. On the other hand, tests carried out at random on specimens of the infant and child population in several centres in this country have shown that lower reserves are not at all uncommon—i.e., in children whose diet has not been specially supervised by any authority. This points to the suggestion that large numbers of infants receive less than the optimum dosage of orange juice recommended by the clinicians. It may also be taken as supporting evidence in favour of the theory which has more than once been propounded that latent scurvy is not a rare condition. When the mothers are questioned about the diet

more children one not infrequently receives the advice that although the doctor (or the welfare bureau) recommended orange juice, "the baby didn't seem to like it" or "it couldn't be afforded" or it was "not considered necessary."

VITAMIN-C EXCRETION IN PYREXIA

It has already been reported by Schroeder and by others that during fever vitamin C is used up more rapidly than it is normally. We have confirmed this finding, e.g., in the observations shown in Fig. 2, on a subject suffering from mild coryzal fever of short duration. The excretion of vitamin C promptly fell within 24 hours of the onset of fever from 19 mg. to 0.7 mg. per day, and remained at a depressed level for a week or more afterwards although the daily dose of vitamin C was continued as before. A larger dose was needed to restore his "reserves" to their original value.

Such a result is important as indicating that the vitamin (in common with certain other metabolites) is utilised at an increased rate in fever. It confirms the need for the provision of a specially ample allowance of the vitamin during convalescence.

Technique of Method

Collection of specimens: need for storage in dark bottles.—The same procedure was adopted for collecting urine as that previously described. The urines were collected during half-day periods with the addition of 5 per cent. of acetic acid and then titrated immediately. In the presence of the acid the loss which occurs up to a period of about 12–15 hours is generally of little practical significance—viz., about 20–30 per cent.—provided the urine is kept in dark bottles. In the light however we have found that the vitamin may be fairly rapidly destroyed, as is shown by the following comparison between acidified urines kept in colourless and in dark-coloured bottles (Tables VIII. and IX.). By about 24 hours the loss may reach

TABLE VIII

TABLE IX

Loss of vitamin C in acidified urine after standing for 24 hours

No. of specimen.	Titration value in mg. per c.cm.		
	Initial value.	Value after 24 hours in dark bottle.	Value after 24 hours in light bottle.
7	0.08	0.05	0.004
8	0.10	0.03	0.005
9	0.10	0.03	0.003
10	0.09	0.04	0.004
11	0.06	0.03	0.003
12	0.04	0.02	0.002

serious proportions. When the urine has to be kept for such long periods, however, a procedure is available, involving treatment with H₂S, by which the ascorbic acid may be preserved or regenerated.⁵

Method of titration.—Only one point calls for special mention—namely, the need for the titration to be carried out rapidly (within two minutes). This has already been indicated but cannot be over-emphasised. The dye solution should be re-standardised frequently and the titration carried out in acid solution. (In the previous paper the strength of stock dye solution, of which 0.05 c.cm. is approximately equivalent to 0.025 mg. of ascorbic acid, was inadvertently given as about 0.05 instead of about 0.10 per cent.)

CONCLUSIONS ON TECHNIQUE

It is stressed that the total daily excretion of the vitamin in the urine should be measured and not merely its concentration. The urine should be collected in dark bottles, as light accelerates the inactivation of the vitamin. The titrations should be carried out as soon as possible after the urine is passed, but it may be kept with comparatively little loss for about 12–15 hours with the addition of 5 per cent. of acetic acid.

For the test dose, about 700 mg. of ascorbic acid should be given per 10 st. of body-weight. If a small response results, this dose should be repeated on one or more further days in order to distinguish between the milder degrees of deprivation and more severe hypo- or a-vitaminosis.

The rapid method of analysis described may estimate small traces of other substances present in urine as well as vitamin C, but this in no way affects its utility as a convenient clinical method for the purposes indicated, as is shown by the fact that the urinary response is found to be closely graded in proportion to the intake of the vitamin and that different subjects show close agreement in response when given the same vitamin intake. When however results of great precision are needed it is possible to refine the specificity of the technique and several alternative methods are indicated.

Summary of Results

1. Studies have been continued of the application of the method previously described and detailed quantitative data collected. The technique of the method and its specificity are discussed (see preceding paragraph).

2. Various graded doses of vitamin C were taken daily by adult subjects over long periods, and it was shown that their urinary excretion of the vitamin reached levels graded in proportion to their intake.

3. The effect of a test dose was similarly investigated and shown to be graded in proportion to their dietary intake, and so also to their "resting levels" before the test dose.

4. Surprisingly little variation was found between individual subjects, the same daily dose of vitamin given to a number of subjects producing after a time an almost identical rate of excretion.

5. It is confirmed, however, that in fever the output drops and the vitamin appears to be "wasted," and an additional dosage is needed to restore the subject to his original level. This result indicates the need for provision of extra vitamin C during convalescence.

6. In normal adult subjects of about 10 st. the addition to a diet fairly low in vitamin C of 3 oranges per day (90 mg. of ascorbic acid) leads to an excretion of about 50 mg., of 1½ oranges (45 mg.) to an excretion of about 30 mg., and ½ orange (15 mg.) to an excretion of about 15 mg. On the last-mentioned regimen the response to a single test dose of 700 mg. of ascorbic acid is of the order of 40–50 mg.

7. The reputed minimum dose of ascorbic acid needed to prevent the earliest symptoms of hypo-vitaminosis C in adult subjects is said to be about 25 mg. per day. In view of the above results therefore a presumption may be raised that the diet has been unduly low in vitamin C whenever the daily excretion falls below a titration value (uncorrected) of about 10–15 mg. per day (i.e., per 10 st. body-weight) or the standard test dose of 700 mg. fails to give a response on the second day. Direct comparisons have still to be made between the mildest clinical symptoms of vitamin-C deficiency and the corresponding levels of urinary excretion.

In our experience, in this country the average daily excretion of normal adult subjects receiving small

liberal) allowances of fruit (or other source of min C) is about 20 mg. per day. (though the needs of infants and children for min C seem to be relatively greater than those of its, the same figures appear to apply approximately their "normal daily excretion"—i.e., when related to a body-weight basis. Thus children about one year receiving the "recommended" ly dose of orange juice excrete not less than 1 mg. of ascorbic acid per day. Their response to est dose, as with adults, is also graded in proportion the "resting level."

Judged by the urinary excretion figures, sub-minimum intakes of the vitamin are not uncommon.

We wish to express our indebtedness to the medical icer of health for West Ham for permission to publish e results obtained on infants attending the local welfare ntre, and to Dr. M. Gilchrist for the great trouble she ok in obtaining the material for the observations at yntonstone. Messrs. Hoffmann-La Roche generously rovided the ascorbic acid used in these tests.

A CASE OF ADULT SCURVY

By PAUL WOOD, M.B. Melb., M.R.C.P. Lond.

FIRST ASSISTANT, BRITISH POSTGRADUATE MEDICAL SCHOOL
HAMMERSMITH HOSPITAL, LONDON

IN 1933 Harris, Ray, and Ward¹ introduced a titration method for estimating the amount of ascorbic acid in urine. This year Harris and Ray reported further experiences,² showing that the test was of value as an aid in the diagnosis of infantile scurvy, their patients having a low ascorbic acid output and failing to exhibit a peak rise after a large dose of the acid, in contrast to normal controls. Observations on adults showed that a low urinary output of ascorbic acid and a low excretory response to test doses went parallel to a history of vitamin-C underfeeding, and to a state of vitamin-C subnutrition as evidenced by a lowered capillary resistance. The following case is interesting because adult scurvy is now a rare disease and because it was investigated on the lines suggested by Harris and Ray.

CASE REPORT

A woman, aged 53, was admitted to the Hammersmith Hospital on Sept. 28th, 1935. She complained of pains in various parts of her body, a rash on her legs and weakness. She was depressed, irritable, and negativistic, so that a complete history was difficult to elicit, and investigations had to be limited. She discharged herself 12 days after her admission.

Prior to 1925 her previous history contained nothing of significance. Her family history was irrelevant. She had been married twice but had had no children. She objected strongly to all questions of a personal nature. She had an early menopause at the age of 43, after which she developed dyspepsia consisting of flatulence, epigastric pain immediately related to food, nausea, and occasional vomiting. She still suffers from these symptoms, and on

account of them she has held to a fairly strict diet over the last ten years. She avoids green vegetables, fruit of any kind, and potatoes, and she boils all her milk; she eats very little meat; her diet consists practically of fish, eggs, custards, milk puddings, bread and butter. At Christmas time in 1934 she had a severe attack of epigastric pain and vomiting and went to bed, where she stayed for four months during which time her diet was stricter than ever. In May this year she began to improve and left her bed. In the middle of August, however, she had a sudden severe pain in the right thigh, and was helped back to bed where she was given aspirin and a liniment. Her landlady, while applying the liniment, noticed bruises on the right thigh, and later a rash appeared on the legs and abdomen, and small hæmorrhages were seen under the nails. The shoulders, knees, left forearm, and right thenar eminence became the seat of painful blue swellings which were exquisitely tender. She was admitted to hospital with the diagnosis of gastritis, purpura, and neuritis.

Examination revealed a pale thin woman of 53, weighing 5 st. 12 lb. She was irritable and depressed. There were extensive petechiæ, especially under the nails and on the legs, and tender ecchymoses in the right thenar eminence and in the right thigh posteriorly. Both knees and both shoulders were tender on pressure and painful on movement, but the swellings had subsided. There was no fluid in the joints and movement appeared to be restricted only by pain. There were no hæmorrhages in the optic fundi nor in the conjunctivæ; there was no blood in the urine nor in the stools; there had been no epistaxis, hæmatemesis, nor hæmoptysis. Her teeth had been removed with the exception of one lower molar which was loose in its socket, the surrounding gum being retracted, hæmorrhagic, and slightly ulcerated; the rest of the gums were pale and hard. The fauces and tonsils were normal, the tongue furred, large, and flabby. No abnormality was detected in the ears.

The heart was not enlarged, there were no murmurs, the rhythm was regular, there was no signs of congestion, and the electrocardiogram was normal. The arteries were not unduly thick for her age and her blood pressure was 150/90. The lungs showed no abnormality, and the costal cartilages and costochondral junctions were normal. The lower border of the liver was 3 in. below the right costal margin. It was somewhat tender on palpation, and the edge was smooth. The spleen could not be felt, and no other intra-abdominal abnormality was detected. The central and peripheral nervous systems appeared normal in all respects; there was no impairment of sensation and apart from the ecchymoses there was no hyperæsthesia; the pupils, tendon reflexes, and cranial nerves were normal.

The red blood-cells numbered 3,200,000 per c.mm., the hæmoglobin measured 58 per cent. by the Haldane method, and the colour-index was 0.9. There were 2.5 per cent. reticulocytes. The mean red cell volume was 80 cubic microns. The platelets amounted to 340,000 per c.mm. The leucocyte count was 5000 per c.mm., of which 65 per cent. were polymorphonuclear and 32 per cent. were lymphocytes. The blood coagulation time was 2 minutes at 37° C., and the bleeding time was 4 min. 15 secs. The erythrocyte sedimentation-rate was 54 mm. of plasma at the end of one hour with the Westergren technique. The blood fragility test showed that hæmolysis commenced with 0.44 per cent. of sodium chloride, and was complete with 0.28 per cent. sodium chloride. The blood van den Bergh test was directly and indirectly negative. The carbon dioxide-combining power of the blood was 46 c.cm. of carbon dioxide (normal, 50-70 c.cm.).

The urine was alkaline on admission with a specific gravity of 1002. It contained a trace of albumin, but no blood or sugar. Rothera's test for acetone was negative. Microscopically there were numerous squamous, epithelial, and granular casts, and a few red blood-cells were seen.

Radiography of the skeleton showed no joint changes, no alterations of structure or density of bone, and no evidence of subperiosteal hæmorrhages. While the patient was in hospital her temperature varied between 97° and 100° F., but was higher than 99° on only one occasion. Her pulse-rate averaged 90.

¹ Harris, L. J., Ray, S. N., and Ward, A.: Biochem. Jour., 1933, xxvii., 2011.

² Harris and Ray: THE LANCET, 1935, i., 71.

INVESTIGATION

The excretion of ascorbic acid in the urine was then investigated and compared with that of a normal control patient of the same weight. The ascorbic acid was estimated in the freshly voided specimens of urine by titration with 0.1 per cent. dichlorophenolindophenol according to the procedure outlined by Harris and Ray.³ Urine specimens voided during the night were preserved with 10 per cent. of glacial acetic acid. The outputs of vitamin for 24-hour periods before and after administration of a massive dose (600 mg.) of ascorbic acid were determined. A control case was used in which there was no history of vitamin deprivation. The findings were as follows:—

TWENTY-FOUR HOURS BEFORE VITAMIN ADMINISTRATION

Scorbutic.—1303 c.cm. of urine, no ascorbic acid found.

Control.—1442 c.cm. of urine, total ascorbic acid found 53 mg.

TWENTY-FOUR HOURS AFTER VITAMIN ADMINISTRATION

Scorbutic.—1681 c.cm. of urine, total ascorbic acid excreted approximately 1.7 mg.

Control.—1049 c.cm. of urine, total ascorbic acid excreted 231 mg.

It was considered that this result proved that the diagnosis of scurvy was correct. The patient was treated with 80 mg. of ascorbic acid in tablet form daily, while she was kept on a vitamin-C free diet. There were no further hæmorrhages, and the petechiæ and ecchymoses were fading when the patient discharged herself.

DISCUSSION

The case illustrates that even to-day, when the existence and importance of vitamins are common knowledge, scurvy still occurs in adults. In this instance a dyspeptic diet was the cause of the vitamin deficiency.

The case bears out the contentions of Harris and Ray that the ascorbic acid urinary excretion test is a valuable aid in the diagnosis of scurvy. The patient received over 1000 mg. of ascorbic acid and excreted only 1.7 mg., and that was after the test dose of 600 mg. A normal control, after a test dose of 600 mg. of ascorbic acid excreted 231 mg.

There can be little doubt that both children and adults store vitamin C in the tissues, for Harris and Ray have shown that the excretion of ascorbic acid continues at an even rate for many days after complete elimination of the vitamin from the diet, and there is no evidence that human beings can synthesise it. That 1000 mg. of ascorbic acid were almost completely retained in the body of this patient suggests that her stores were very low.

The anæmia of scurvy is of interest. It is generally recognised that vitamin C is necessary for blood formation, and that a definite reticulocyte response can be demonstrated in cases of scurvy with anæmia treated solely with vitamin C. The anæmia may be cured completely with this treatment alone if it is not associated with an iron or other deficiency. Hæmoglobin estimations indicate that the anæmia, when pure, is usually orthochromic,⁴ and the red cells are usually normocytic,⁴ as measured by the method of Price-Jones. In this case the anæmia was moderate, and appeared to be orthochromic and normocytic. It was not possible to estimate the reticulocyte response owing to the patient's objections. The bleeding time was prolonged and the blood-platelets were normal.

SUMMARY

A case of frank adult scurvy is reported. The cause of the condition was a long-continued dyspeptic

diet which was almost free from vitamin C. Examination of the urine showed that the patient was excreting no ascorbic acid by this route, whereas a control patient excreted 53 mg. in 24 hours. After an initial dose of 600 mg. of ascorbic acid by mouth the scorbutic patient excreted 1.7 mg., whereas the control excreted 231 mg. The patient received a further 80 mg. per day for a week, while she remained on a diet containing no vitamin C. During this time she excreted no more ascorbic acid. No further hæmorrhages occurred and the original petechiæ and ecchymoses were fading when the patient discharged herself from hospital.

The biochemical part of this investigation was carried out by Dr. E. J. King in the biochemical laboratory of the British Postgraduate Medical School, and to him my thanks are due. I also wish to thank Prof. F. R. Fraser for his help and interest in the case.

THE SIGNIFICANCE OF
LATERAL ABERRANT THYROIDS

By A. L. D'ABREU, M.B. Birm., F.R.C.S. Eng.

SENIOR ASSISTANT IN THE SURGICAL UNIT, THE WELSH
NATIONAL SCHOOL OF MEDICINE, CARDIFF

THE peculiar behaviour of misplaced thyroid tissue has been studied by many observers. It is now established that thyroid tissue occurring in regions remote from the neck and especially in bones represents metastasis from a malignant growth of the thyroid which may be actually a small undetected malignant adenoma (Joll,¹ Dunhill,² d'Abreu³). If however tissue of the thyroid type is found in the neck apart from the normal gland, the explanation is not so defined or simple. Such tissue may occur either above, below, or lateral to the gland proper. Extremely rarely the aberrant tissue may be found in the larynx.

There is no need here to describe the embryology of the thyroid; it is sufficient to note that the thyroid commences high up in the primitive pharynx as a median pouch between the second arch and the tuberculum impar and then descends relatively caudally; the ultimate bilobed shape of the gland depends upon a lateral attachment to the third arch on each side and glandular tissue runs along the artery of this arch and ultimately fuses with the epithelium of the fourth lateral pouch (Frazer⁴). Occasionally portions of gland continue to pass caudally and the existence of intrathoracic pieces of thyroid tissue is well known. Another site for ectopic thyroid tissue is at the back of the tongue in the region of the foramen cæcum. Anatomically, physiologically, and pathologically thyroid tissue in these two sites differs greatly from lateral aberrant thyroids (Billings and Paul⁵); the latter usually show malignant changes, the former rarely, if ever, do. Further, myxœdema may follow excision of superior and inferior masses (Grace and Weekes⁶), but it never follows removal of lateral thyroid tissue.

In contrast to the simple embryological explanation of superior and inferior thyroid tissue is the obscure origin of lateral aberrant thyroid tissue. Anatomists are unwilling to accept an origin from the fourth arch or the ultimo-branchial body; the more obvious explanation seems to be that as the blood-vessels in the neck, to which the thyroid is intimately attached, grow outwards they carry with them small portions of thyroid tissue (Frazer,⁴ Woollard⁷). The following case suggests that an origin from the fourth arch region is not impossible.

³ Harris and Ray: *Ibid.*, p. 462.

⁴ Parsons, L. G., and Smallwood, W. C.: *Arch. Dis. Childhood*, 1935, x., 327.

CASE 1. *Lateral aberrant thyroid occurring in a branchial cyst.*—A woman, aged 23, was admitted to the General Hospital, Birmingham, on August 14th, 1932, under the care of Mr. Rose, with a lump in the right side of the neck which had appeared five years previously and had remained the size of a marble until a recent enlargement had occurred. The general condition was excellent: a painless, cystic swelling $1\frac{1}{2}$ in. in diameter presented in the posterior triangle of the neck behind the lower third of the sternomastoid; there was no adherence to the skin and the lump was movable on the deeper structures. The preoperative diagnosis was "branchial cyst." Mr. Rose operated and exposed a cyst, the pedicle of which ran behind the great vessels of the neck up to the pharynx to which it was attached and from which it was dissected. During the removal several small hard swellings were felt in the cyst. Convalescence was uneventful and the patient on inquiry early this year (two years and six months after the removal) was well and completely free from recurrence.

The cyst is lined by ciliated columnar epithelium, part of which is arranged in complicated papillary

FIG. 1 (Case 1).—Thyroid tissue in a branchial cyst. ($\times 60$.)

to the pharynx. Branchial cysts are usually lined by squamous epithelium, but branchial fistulae are commonly lined by columnar ciliated epithelium. There is some evidence therefore from this case that certain lateral aberrant tissue may develop

FIG. 2 (Case 2).—Photograph showing the lump behind the right sternomastoid.

FIG. 3 (Same case).—The tumour.

FIG. 5.—Tumours removed in Case 3.

processes, the solid portions consist of poorly developed thyroid tissue in which some colloid is present (Fig. 1).

It will be seen from Fig. 1 that the tissue is papillomatous in type. The evidence against the tumour being solely a lateral aberrant thyroid showing cystic degeneration is the presence of ciliated epithelium and the fact that the cyst was attached

from tissue in the neighbourhood of the fourth pouch. It must be noted however that thyroglossal cysts are lined by squamous epithelium and may be columnar and ciliated (Joll⁵). It would therefore be foolish to exaggerate the significance of this case as indicating an origin from the fourth pouch.

It is now well recognised that these lateral aberrant thyroids are extremely dangerous as potential areas of malignant disease. Dunhill says: "These misplaced bits of tissue . . . foredoom the host to carcinoma from before the day of birth." Others, although regarding them with grave suspicion, are not quite so gloomy in their prognostications. In recording 4 cases, Dunhill² points out that 2 proved fatal from secondary malignant metastases. The malignant tendency is undoubtedly due to the extreme degree of papilloma-formation seen in the intracystic masses. In reporting 35 cases, Billings points out that 70 per cent. were papillary in type. Dunhill, discussing the papillary arrangement, emphasises its potential malignancy in thyroid tissue whether in normal or abnormal situations; it occurs in adolescent and toxic goitre and has been produced in brook trout; he goes on to suggest that stimulation, whether pathological or physiological, causes this architectural type because of the inherent properties of thyroid epithelium; he asks if papilliferous adenocarcinoma is due to stimulation of a part of the thyroid which is subsufficient through maldevelopment or malposition, or whether it is due

FIG. 4 (Same case).—Section showing malignant change. ($\times 8$.)

to abnormal stimulation. From puberty onwards for some 10-15 years the thyroid is subjected to an increasing strain. Dunhill points out that of 45 reported cases the condition was obvious in 25 before the age of thirty, and in 15 before the age of twenty; this suggests that the abnormally placed tissue responds to the acting stimuli by a cystic papillomatous hyperplasia. Of the 35 cases collected by Billings and Paul,⁵ 26 were in females and 6 in males, the sex-incidence not being reported in 3; the extra burden of menstruation, pregnancy, and lactation may account for the greater stress thrown upon the gland in the female.

Why the tendency to papilliferous formation should be more marked in lateral aberrant thyroids than in the superior and inferior median displacements remains unexplained. Whatever be the cause of the papillomatous change, the menace of carcinoma here,

FIG. 6 (Same case).—Section of tumour showing colloid vesicles and papillary structure. ($\times 45$.)

as in the breast, rectum, and tongue, is undoubted and all published series of lateral aberrant thyroids show that this complication occurs frequently although it may be delayed for many years, as in the following case.

CASE 2.—Mrs. A., aged 69, was admitted on March 7th, 1934, to the surgical unit at the Cardiff Royal Infirmary complaining of a lump situated behind the right sternomastoid muscle about $1\frac{1}{2}$ in. above the clavicle (Fig. 2). This was painless and had existed for over two years, with progressive increase in size; there was some dyspnoea and the patient had become more nervous before admission. There was no family history of goitre. On examination the patient was well developed but pale; the pulse was irregular and varied between 110-140 beats per minute; there was auricular fibrillation and the heart was enlarged. In the posterior triangle of the neck on the right side there was a hard large spherical mass 2 in. in diameter and above this a second nodule could be felt; both were movable. The thyroid appeared to be normal and moved on deglutition. At operation under general anaesthesia the swellings were removed without difficulty; the upper tumour had the characteristic bluish-black colour of lateral aberrant thyroid tissue. The larger lower mass was not so dark, and on pathological examination it was seen to have undergone malignant change into papilliferous carcinoma (Figs. 3 and 4). Convalescence was uneventful, but unfortunately efforts to trace the patient have been unsuccessful.

Such a case occurring late in life suggests that certain unexplained so-called branchiogenetic carcinomata may have their origin in misplaced thyroid tissue.

The fourth case of lateral thyroid tumour I have seen is characteristic of the earlier type; diagnosis is rarely made correctly, and although I had had the good fortune to study personally the case recorded

by Forty,⁹ I diagnosed the condition before operation as one of tuberculous adenitis.

CASE 3.—A man, aged 30, a patient in the surgical unit of the Welsh National School of Medicine, had had a swelling in the right side of the neck for five years; this had appeared after a tooth abscess and quinsies had occurred. On examination two swellings existed half-way down the right sternomastoid, one being partly in the anterior triangle and under the sternomastoid, the other being behind the muscle; they were soft in consistence and semifluctuant; there was no movement on deglutition, but the swellings were freely movable on the surrounding structures. As stated, the preoperative diagnosis was tuberculous glands. At operation (Feb. 5th 1934) through a curved incision two bluish-black tumours were exposed and a diagnosis of lateral aberrant thyroid tumour was made. Both tumours were well encapsulated and were easily removed, convalescence being uneventful. In view of the possible danger of malignancy, the patient's condition has been carefully followed; he remains well and free from clinical evidence of recurrence a year after operation.

Fig. 5 shows the two tumours: the upper really consists of two swellings; the multiplicity of these little tumours has been noted by Dunhill² and Billings and Paul.⁵ The lower tumour has been opened and shows small rounded masses projecting into cystic spaces. Fig. 6 is taken from a microscopical preparation from one of these masses, and shows well-filled colloid vesicles. The papillary structure is noteworthy and is an indication of the potential malignancy of the tumour.

CONCLUSION

The embryological explanation of laterally misplaced thyroid tissue remains uncertain. That the outgrowing blood-vessels carry the tissue with them is the modern view; origin from the fourth pouch or from the ultimobranchial body is unlikely, but is accepted by some authorities and is in some respects supported by Case 1 reported here. The pathological changes in these cases are very different from those of aberrant thyroid tissue found in a superior or inferior position; intracystic papilloma-formation is common and this often proceeds to malignant change. Symptoms of hypothyroidism after removal are unknown, and the cases are thus in contrast with those of superior aberrant thyroid where such symptoms are not uncommon. Clinically the condition is not usually diagnosed until operation. The most important diagnostic appearance is the bluish-black colour, and unless this fact be known the surgeon may be puzzled by the appearances and may regard the condition as a melanotic growth. If such tumours are seen careful and complete extirpation is essential because of the danger of their becoming malignant. If a correct preoperative diagnosis be made there is no justification for abstaining from immediate operation. The prognosis is doubtful and all cases must be carefully followed up. The best treatment for recurrence appears to be excision associated with radiotherapy.

I wish to thank Mr. B. T. Rose for allowing me to report the first case.

CLINICAL AND LABORATORY NOTES

PULMONARY EMBOLI OF LYMPHATIC ORIGIN

By ALEXANDER G. CROSS, M.B. Camb.

RECENTLY HOUSE SURGEON TO THE SURGICAL UNIT,
ST. MARY'S HOSPITAL, LONDON

CHYLOUS cysts of the mesentery and mesocolon were first fully described by Rokitsansky in 1842. Since then some 200 cases have been reported.^{1,2} The following case is recorded because of the comparative rarity of the primary condition, and because of the features shown after operation.

History.—A. B., aged 20, a nurse, was seen in January, 1935, and complained that for six years she had had a constant dragging pain in the left iliac fossa, with attacks of a colicky nature, when the pain radiated to the right iliac fossa. It had not been severe enough to keep her awake at night, but was getting worse. It was accompanied by nausea, but no vomiting. It had no relation to food, and was not relieved by lying down. The appetite was good and the bowels open regularly without aperients. She had been kept in bed for a fortnight, six weeks previously, and the pain had been slightly relieved.

Examination.—There was ill-defined tenderness in the left iliac fossa, with a feeling of resistance on deep palpation; but no other abnormality was discovered by clinical examination. Radiography showed no lesion of the gastro-intestinal or renal tracts. Blood count showed a relative lymphocytosis. Vernes's test was negative.

At operation (Jan. 23rd, 9.50 A.M.) a midline subumbilical incision was made and a unilocular cyst, the size and shape of a butcher's sausage, was found in the sigmoid mesocolon. On its outer surface were a number of small white spots. Some clear fluid was aspirated, the cyst excised, and the abdomen closed.

Pathological reports.—Fluid of cyst: clotted rapidly; nothing abnormal on bacteriological examination. Cyst wall: fibrous elastic tissue and muscular tissue arranged as in a vein; in a few parts there is an endothelial lining, but often it is bare; the white areas consist of fibrin, and necrotic tissue which is partially calcified.

After-history.—On the day after the operation, at 10.20 A.M., the patient, who had been quite comfortable, had a sudden attack of dyspnoea, with pain in the right side of the chest. She was pale, with a feeble irregular pulse. Oxygen was given continuously, and within two hours the pain and dyspnoea had disappeared, and the pulse had become more regular. At 1.15 P.M. on the same day there was another attack of severe dyspnoea, with pain on both sides of the chest. She was pale, and the pulse was barely perceptible at the wrist. Coramine 1.7 c.cm. was given, with oxygen, and she became much better in an hour. On Jan. 29th, at 11 P.M., there was a third attack of dyspnoea, with pain in the upper abdomen. The pulse and colour of the patient remained normal. Morphia gr. $\frac{1}{4}$ and oxygen were given, with improvement in an hour. The remainder of the convalescence was uneventful. She got up on Feb. 11th, and was discharged on Feb. 24th.

The three attacks of dyspnoea after the operation were undoubtedly due to pulmonary emboli. They appeared, however, earlier than is usual in post-operative cases. No large vessels were encountered in the removal of the cyst from the mesocolon, and no ligatures were applied. The lymphatic connexions were severed and it is to be expected that clotting of lymph occurred in these lymphatics, extending centrally. Fragments of these clots probably reached the general circulation through the thoracic duct and lodged in the right auricle. There, by deposition of fibrin, they would increase

in size, and they would finally pass through the pulmonary artery to cause obstruction of its branches in the lungs.

I should like to express my thanks to Prof. C. A. Pannett for permission to record this case.

ORCHIDECTOMY ON THE HIGH SEAS

By PHILIP E. F. FROSSARD, M.R.C.S. Eng.

SURGEON, P. AND O. STEAM NAVIGATION CO.

A STEWARD, aged 30, with no previous history of disease, was admitted to the ship's hospital at 6.30 P.M. on Oct. 23rd, 1935. He had been struck on the scrotum by a cricket ball—a full pitch from a fast bowler—two hours previously. He was able to walk on board but was in considerable pain.

Local examination revealed a firm, tender swelling of moderate size of the right side of the scrotum and contents. At this stage there was no pain, tenderness, or swelling over the inguinal canal.

The patient was treated with rest and compresses, morphia gr. $\frac{1}{4}$ being administered after examination. The progress was apparently satisfactory. The patient was comfortable and the swelling began to subside. Five days later, on Oct. 28th, he complained of abdominal pain and of having had a restless night. The temperature was 99° F. and the pulse-rate 80. There was an increase of swelling and tension. The scrotum was red and oedematous. There was definite swelling and tenderness over the inguinal canal extending over its entire length and into the right iliac fossa. Owing to the exacerbation of symptoms and the possibility of added infection, it was decided to explore the scrotal contents and operation was performed on the same day.

The ship's operating theatre (appointed for the purpose) was made ready and the patient was on the table within an hour and a half, the ship having eased down to dead slow. The anæsthetic, administered by Dr. E. O'Brien, the assistant surgeon, consisted of ethyl chloride followed by open ether, a preliminary injection of morphia gr. $\frac{1}{4}$ and atropine gr. 1/100 having been given. Incision revealed the vaginal sac filled with blood clot and altered blood. The testis was seen to have been split near the centre right through to the epididymis, the split being in the transverse axis. The parenchyma bulged through the cleft tunica albuginea; the epididymis and cord were a dark purple, grossly swollen. It was evident that a condition of comparative local stasis of the blood circulation was present.

The left testis being uninjured and apparently normal, it was decided to remove the damaged organ, complete with the epididymis and cord at the level of the external abdominal ring. The infiltrated and inflamed scrotal sac was drained through a stab wound at the lower pole of

The testis after removal, showing the injury. The white line points to the split edge of the tunica albuginea.

the scrotum. The patient was returned to bed and made a satisfactory recovery. Three weeks later, on arrival in London, he was landed "convalescent."

It may be of interest to note that the operation was performed off Cape Guarda Fui in calm weather. The stopping of a ship at sea is a serious matter; like the stopping of a railway train, it is not to be undertaken lightly and there are penalties for the "improper use of the emergency signal." Unless sufficient way is maintained, the ship will not answer

to the helm and will fall off her course, and "not under control" signals have to be hoisted which occasion considerable concern to neighbouring craft. Hence on surgical occasions a speed is ordered which reduces vibration to nil and yet keeps the ship on her course.

Nowadays operations at sea are not the nightmares of old. Full aseptic technique is employed and only two conditions are required—namely, that both surgeon and patient are "sailors."

MEDICAL SOCIETIES

MEDICAL SOCIETY OF LONDON

At the meeting of this society held on Dec. 9th, the President, Prof. G. E. GASK, occupying the chair, a discussion on the

Care and Treatment of Difficult Children

was opened by Dr. REGINALD MILLER, whose remarks are printed on p. 1393.

Dr. WILLIAM MOODIE said that every physician, whether a psychologist or one more or less orientated towards the physical side, must approach the problem of health or ill-health in the same way. It was necessary to define the medical attitude to the question, seeing that the lay press constantly printed articles telling parents how to do their jobs; there was being created in this country a kind of psychology consciousness, not perhaps entirely confined to laymen, which had antagonised scientific thinkers and had retarded the study of practical psychology. The latter could be an excellent servant, though as a master it might be disturbing. Theory was all right in its own place as a background: the foreground should be occupied by practice. He did not feel clear as to what was meant by the "difficult child" unless it was a mixture of the nervous child and the one who presented behaviour disorders or problems. The children under consideration were classifiable under two groups: (1) children who, through exhibiting some disorder of behaviour or conduct, showed nervous symptoms or made one feel that they were laying the foundation of what were termed functional nervous disorders; (2) delinquent children, manifesting something rather different. Every normal child behaved in an unusual way at times, because in the early days learning how to behave was not easy; it seemed to be a kind of match or contest "Self versus the Rest." The child made mistakes, because all learning was largely a matter of trial and error. When the learning period had passed, these slips of conduct must be regarded more seriously. A child sucking its thumb at six weeks of age excited no comment, but at six years this was a different matter. And every child was enuretic at some period. Some errors seen in later childhood might be no more than a persistence of habit. If a child was sucking its thumb at 8 years of age it was generally doing other unusual things also, such as sleep-walking or nail-biting, and was either shy or aggressively violent. Complexes of symptoms might be found which were an external evidence of some deep-lying mental disturbance. In these conditions lay the beginnings of the psychoses and psychoneuroses which showed in later life. Hence the "difficult child" was worthy of careful investigation and every therapeutic effort.

Behaviour was the result of two separate but inter-

dependent sets of circumstances: those (1) of the moment, (2) of the past. Such factors as fatigue, hunger, illness would affect the behaviour in definite ways. The investigation of the condition must be undertaken in a spirit of detachment. Every normal adult had within him the urge and desire to manage children, and in the presence of misbehaviour of the child to adopt a minatory attitude, but didactic methods seldom carried one far in psychology. Cause and effect must be linked only after careful observation, and every examination of a child must include a complete physical one, especially so as to detect any metabolic errors. And all information concerning the environment in which the child had been brought up must be obtained. The treatment must be so planned as to counteract the forces at work. There were four convenient groups from this point of view: (1) Obviously stable children who had to try to adapt themselves to abnormal environment; (2) children who, though stable, had been taught a bad style of living, and so experienced difficulties in adaptation; (3) unstable children who could not adapt to any conditions; (4) the mentally defective and psychotic.

There was, he said, an erroneous idea that the bright child must be kept back academically. Some children were being literally worn out by their own activity. In these children a frequent diagnosis was "nervousness," and the prognosis was usually "He will grow out of it," or "Keep him away from school and he will do well." For these restless energetic children Dr. Moodie considered that there was but one remedy—namely, real academic work: arithmetic, mathematics, reading, and writing. It was necessary that the balance between intelligence and attainment should be adjusted. Schoolmasters could not make this estimation. Dr. Moodie thought that the reliability of school reports sometimes varied inversely with the fees paid, or with the square or cube of the fees paid. Every child was the subject of fears and anxieties, and if his potential energy was dammed up, those fears became accentuated. In the presence of hard academic work the fears were seen to fade. An important matter was the need for a sense of security. This depended on a stable home and reasonable discipline. It was not possible to ensure the former, but discipline was possible for all, though many parents were incapable of exerting it reasonably. Much benefit followed the expression by the child of his thoughts and their subsequent discussion. The great object was to release repressed wishes. In this group of children much research still remained to be done.

Referring to delinquents, Dr. Moodie said that last year he examined 1700 delinquent children who had been tried in the London courts. Among them he found some interesting sexual cases, and some curiosities; but he had never seen any kleptomaniac children. A curve made of results of intelligence

tests among these children were practically of the same shape as that for the normal community, except that the peak was 93 instead of 100, indicating that delinquents as a whole were slightly dull. In all of them there was aggressiveness and resistance to authority, which, in many cases, could be traced back to disturbed marital conditions in the home. Also, a number of these children were compared in educational attainment with a large number taken from ordinary schools; it was found that the number of those backward in arithmetic was more than four times as great as those in ordinary schools; the relative degree of backwardness in the subjects of reading and writing was even greater. Dr. Moodie urged that the few mentally abnormal children in this group should be treated by some form of psychological analysis. Many of the children seen were not in themselves psychopathic and could be treated by general methods, such as by the adjustment of their education or the adjustment of their discipline.

Dr. W. G. WYLLIE pointed out that there was a small group of children who were unable to read or write at 9 to 14 years of age. At schools with large classes such children were either kept down with children younger than themselves and remaining at the bottom of the class even there, or they were said to be mentally deficient and were sent to some special school. For the defect of those children he thought the proper name was "visual imperception." They were able to recognise each separate letter, but stringing letters together to form words confused them. Sometimes parents, impressed by what the teacher said, thought they would see the doctor about them, as they seemed intelligent, and could go shopping successfully and bring back the right change. With the assistance of a psychologist at a child guidance clinic they changed from morose to happy children. He wondered whether the L.C.C. would have intelligence tests done on any large scale in the future.

Dr. C. F. HARRIS said he would like to underline Dr. Moodie's remarks about parental indiscipline, because so many of the children who seemed to have run across authority seemed to be suffering not so much from any evil trait or incompetence of their own, but from the fact that the parents themselves had not been subject to discipline, and so had no idea how to bring up their children. How many children stigmatised as "difficult" would be so under conditions which were normal? He agreed with Dr. Miller's suggestion to get such children away from their home surroundings and send them to a preparatory school. Instead of seeking to establish this "difficulty" as a clinical entity it would be well to realise that the children concerned were normal human beings under abnormal circumstances.

Dr. R. A. YOUNG agreed that this was a question of environment and parental control. The present generation of children had been brought up under rather happy circumstances and had been the friends of their parents. Perhaps there were already indications of a swing of the pendulum to a different state of things.

Dr. G. W. B. JAMES said the title "difficult children" seemed to boil itself down to "difficult parents"; of late years in his out-patient department his method had been to talk more to the parents than to the child. He fully agreed with Dr. Miller's remark that some fathers constituted excellent mothers. It was difficult for many homes in these days of economic stress to be run without a feeling of chronic anxiety, and anxiety exerted a tremendous influence

on the children. This was not confined to the poorer homes where unemployment always hovered; the rich man would return home and bewail that shares were down, and he was likely to be ruined. Examination of the parents and of the atmosphere of the home were the main factors in the treatment of difficult children.

Dr. D. W. WINNICOTT referred to the little band of psychotherapists who were content to peg away at a certain method of investigation which did not affect general practice because so few children could be treated by it. The parental factor was undeniably important, but he contended that it led nowhere in the matter of scientific investigation, because if the parent was difficult little could be done, the feeling being that the said parent ought to have been treated when young. It was not a question of telling some parents what to do, but of making them less anxious and rendering them happy in their home relations, an impossible task if they were not already happy. In the delinquent child the lack of parental love was a very important factor; and earlier experiences such as the lack of love of the infant were also significant. Many of these children were unwanted infants, and were passed from one person to another. The study of children need not be the study of their parents; much could be done by a study of the children themselves. Dr. Winnicott had been able to carry out a successful analysis of children, even when the external circumstances could not be altered and had remained unfavourable. Some children who looked as if they were mismanaged were extraordinarily difficult children who dealt with underlying depression in a manic way, and who, later in life, would become manic-depressives. In many cases of children who had been sent to him because the parents were bad he found himself sympathising with the parents.

Dr. MILLER, in reply, raised the question of the likelihood that children brought up in flats in central London who were unable to go out except fully clothed, and then not into playing fields, might reflect characteristics due to this unnatural environment. He considered that children of divorced parents mostly suffered from the parental side of their lives. It might be said that one mother was bad and one father was bad, but when a child had four parents it was something fairly severe for the child to put up with. His experience of school people was that they dreaded having the children of divorcees. He feared that the wealth of criticism and the spate of articles on the bringing up of children would have, as one result, the increasing of anxiety on the part of the mothers.

Dr. MOODIE, in reply, said he thought children could be brought up well in flats, though central London flats had not the advantages of those on the borders of Regent's Park. In an undue proportion of homes some disturbance of the marital situation existed; and many children came from broken homes. But if children were not subjected too long to disturbed homes and the children themselves were stable, they were able to get over their bad circumstances fairly well. He often pointed out to parents the difference between responsibility and guilt; one could be responsible for a situation without being blameworthy. The lateness of learning to read and write to which Dr. Wyllie had called attention was really an inability to appreciate position and form, which extended beyond the written word to other things.

MIDLAND MEDICAL SOCIETY

At a meeting of the Birmingham Medical Institute section of this society, held on Dec. 4th. with Prof. W. H. WYNN, the president, in the chair, a paper was read by Mr. J. W. RIDDOCH on

Surgical Shock

He said that Boise, writing in 1907, was apparently the first to put excessive sympathetic irritation among its causes. Work done during the late war had resulted in the toxæmic theory of shock being generally accepted, but in more recent years experiments by M. I. Smith and others rendered it untenable. Blalock had shown the importance of local fluid loss in experimental traumatic shock, but though the work of Holt and Macdonald and of O'Shaughnessy and Slome confirmed that of Blalock, they suggested that a nervous factor was also at work. It would be hard to convince clinicians that surgical shock was in no way related to centripetal nervous influences.

The clinical picture of advanced shock included a low blood-pressure, but the early stage might show a rise of, or no change in, the blood pressure. Even at this stage concentration of the blood had been demonstrated and there was diminution of the pulse pressure. Sensory stimuli caused rises of systolic pressure, and only later was there a fall in mean pressure with a big reduction in blood volume.

The causes of sympathetic activity included the unpleasant emotions (e.g., fear and anxiety) and pain, cold, and asphyxia. Such factors were recognised clinically as important in producing or intensifying shock. In postoperative shock and in wounded men (Cannon) the blood-sugar level was always found to be raised, and Mr. Riddoch showed that the rise in blood-sugar which occurs during abdominal operations under general anaesthesia could be stopped by splanchnic analgesia. This indicated that the hyperglycæmia was due to sympathetic action, and supported the theory that the raised blood-sugar in shock was associated with sympathetico-adrenal stimulation. Sherrington and Copeman (1893) had demonstrated a local increase in the specific gravity of the blood on stimulation of the sympathetic supply to the thyroid gland, and Bainbridge and Parkinson (1907) that chromaffin tissue was absent in death from postoperative shock, suggesting that there had been an intense outpouring of adrenaline. Bainbridge and Trevan (1917) produced shock with infusions of adrenaline and believed that the blood volume was reduced. Freeman (1933) with infusions of adrenaline got a reduction in blood volume of 14 per cent., and this was prevented by ergotoxine. In other experiments sham rage reduced the blood volume by 22 per cent., but this did not occur after ergotoxine, or after previous removal of the sympathetic chains. Thus excessive sympathetic activity was known to occur in shock, and all the known features of shock could be produced by excessive sympathetic stimulation.

The curious apathy and diminution of sensation was interesting in the light of recent work. Feng (1933) ascribed decreased sensibility, caused by injury to a piece of frog's skin, to liberation of potassium, which was present in higher concentration in the cells than the fluids of the body, and D'Silva (1933 and 1934) found that adrenaline and other sympathetic stimulants produced a rise in serum potassium. This liberation of potassium might well be the cause of the sensory depression observed in the shocked state.

The theory of sympathetic hyperactivity helped to explain why pleasant surroundings and the avoidance of mental stress are desirable, and why no surgeon likes to deal with the over-anxious type of patient. The good bedside manner thus acquired scientific sanction; and the principle of free choice of doctor had a physiological background.

THEORIES AND TREATMENT

Prof. SEYMOUR BARLING regarded circulatory collapse as the most noteworthy feature of secondary traumatic shock; the systolic pressure might fall to 90 mm. Hg or less, but this was not inconsistent with ultimate recovery. The mental condition varied, and in the presence of a painful lesion restlessness persisted and seemed to hasten the downhill progress. In the shock-like condition seen in gas-gangrene or other forms of overwhelming sepsis, the patient might be delirious, or alert and coherent up to the moment when he lay back dead. The clinician and the experimentalist had studied the problems of shock extensively but so far inconclusively. The experimentalist sought to produce and analyse the condition freed from all secondary factors which might disturb his experiment, whilst the clinician, finding a shock-like condition present under a number of diverse circumstances, sought common underlying factors as an explanation of all. To those who were doing surgery during the war, Dale's theory that shock is caused by histamine-like bodies of a depressor type, produced in the damaged area, was always attractive. Product as it was of the experimental methods, it had now been almost universally disproved by the experimentalists. Nor had it received much support on the clinical side; for although at first it seemed to explain the severe shock associated with burns this explanation broke down when it was found that tannic acid treatment, though otherwise useful, did not lessen mortality in the first 48 hours when shock was the effective cause of death. The theory that shock arises from fluid loss into the traumatised area by exudation of plasma and bleeding independent of external blood loss had always been satisfying to the clinician and had recently been supported by more exact experimental research. It explained the circulatory collapse and the value of remedies known to be helpful. It would be a mistake, however, to overlook the fact that more than one factor may be at work, and that in different types of clinical shock these factors may be effective in varying degree. That nerve-impulses from the traumatised area may play a part in the general depression of vitality seemed reasonable. The relationship of pain to shock; its effect in prolonging and developing the condition; and the beneficial effect of anaesthetics and analgesics had always been apparent to the clinician and seemed to support his contention that nervous influences play a part in the syndrome.

Until recently treatment had been empirical rather than scientific; in general it followed right lines and under conditions of emergency resolved itself into the war-time measures of morphine and rest to allay pain, blankets and hot-water bottles to give warmth, and hot sweet tea to supply fluid and mild stimulation. Undoubtedly prevention, and measures applied at an early stage, were more satisfactory than treatment of established shock. After the general comfort of the patient had been secured by rest, warmth, and morphine, active treatment was called for to deal with the fluid depletion; and in general the depletion of the blood volume in hæmorrhage or shock was best overcome by fluid from alimentary sources. intravenous infusion of saline was disappointing.

The gum-saline infusion of Bayliss was more satisfactory and should certainly be given in the presence of a blood pressure of 90 with a tendency to fall. There appeared to be no advantage in transfusing blood unless hæmorrhage had been the main factor in producing shock. In the natural anxiety to warm up the patient care must be taken to avoid excessive fluid loss by sweating—a fact sometimes overlooked. When active surgical treatment became necessary nitrous oxide and oxygen was undoubtedly the best of the general anaesthetics, with open ether in the second place. There were definite advantages in the use of local anaesthetic when applicable—especially in head injuries. No support had been received for the suggestion that spinal anaesthesia might assist the surgeon in dealing with a patient already suffering from shock.

THE ANÆSTHETIST'S PART

Dr. L. T. CLARKE said that the problem of surgical shock, or more particularly, its prevention, was an everyday matter for the anaesthetist. Formerly the usual prelude to an abdominal operation was a period of acute starvation punctuated by intensive purgation. The patient came to the table with his liver depleted of glycogen and his tissues dehydrated, and it was little wonder he suffered from shock. To-day pre-anaesthetic preparation was the antithesis of this, and the sedatives now in use had done much to eliminate psychic shock. It seemed a fine thing that a patient could be put into a deep sleep and so made unaware of the induction of anaesthesia.

Shock was a state of general depression and its main feature was a diminution in the volume of circulating blood. Where was the missing blood? Experiments on circulatory failure in frogs had shown that a large proportion of the blood stagnates in the liver. If, as was possible, this was also true of man, it followed that squeezing of the liver is a better method of resuscitation than cardiac massage, in that by driving the blood towards the heart it provides the natural stimulus to contraction—namely, distension. From the anaesthetist's point of view shock occurring during operation might be due to hæmorrhage, trauma, overdosage of anaesthetic, oxygen-deficiency, loss of body temperature, or length of operation. For hæmorrhage the surgeon could not be held wholly responsible: an ill-chosen anaesthetic might increase bleeding; for example, in radical amputation of the breast patients seemed to show less shock with chloroform and oxygen than with the more stimulating ether or the more congesting gas-and-oxygen. Trauma must be considered in the light of tissue destruction and nerve stimulation. Tissue destruction was the surgeon's province, yet here again the inadequate anaesthetic which failed to abolish muscle tone would cause him to be more traumatic than necessary. "I put my faith in deep anaesthesia," said Dr. Clarke; "fluctuating depths of anaesthesia invariably cause shock." In some types of operation nerve stimulation, with resultant reflex shock, could be obviated by nerve-block methods of anaesthesia. In these days of surgical diathermy it must be remembered that the diathermy electrode provides a point of intense local stimulation; the remedy was deeper general anaesthesia or some form of nerve-block. With regard to oxygen deficiency, the ill-effects of partial cyanosis over a long period could hardly be exaggerated; a clear airway was a vital necessity. The maintenance of body temperature, again, had a great influence on shock; draughts and unnecessary exposure must be avoided, but a too hot theatre was as bad as a too cold one.

A special problem arose when the patient was shocked before operation. Here there was a golden rule: the only case of shock that is not benefited by delaying operation is the one caused by active bleeding. Even here operation should be preceded by some attempt at fluid replacement, preferably by blood transfusion. The best anaesthetic in established shock was gas-and-oxygen. Spinal anaesthesia was to be avoided because it paralysed vasoconstrictor nerves. The solution of all problems was found in careful preoperative preparation, unfluctuating anaesthesia, and gentle surgery.

OPINIONS AND EXPERIENCES

Dr. STUART McDONALD believed that the histamine theory of shock was now exploded. The shock-producing effects of protein-cleavage substances should be considered, as in intestinal obstruction, acute pancreatitis, &c. The blood volume changes were important in shock; 47 per cent. of the circulating fluid might be lost with a traumatised limb. The sympathico-adrenal reaction was probably a defence mechanism in shock and not a direct cause. The vasomotor reactions might be regarded as an effect of stimulation of the vasodilator centre; or it might be that the vasodilator nerves were activated by acetylcholine in traumatic shock. The final collapse might be due to failure of the vasoconstrictor mechanism to allow of adequate medullary blood-supply. The influence of the nervous system was of great importance in shock.

Prof. BECKWITH WHITEHOUSE described some of his observations on obstetric shock. The element of fear, he said, was not uncommonly induced by comments in the press. In some cases the amount of trauma was negligible but shock was nevertheless severe. He recalled the case of a woman of excitable type who read medical literature and in whom demonstrable fear was exaggerated. She made her will the day before labour. She had a perfectly normal labour, but a short time afterwards she died of sheer fright. In gynaecological surgery, while a severe operation would cause shock in an unemotional patient, the apprehensive patient was a much more dangerous problem. The emotional factor played a large part in the relative frequency of deaths from illegal operations.

Dr. H. W. FEATHERSTONE stated that there were two causes of shock in simple dental gas anaesthesia—namely, asphyxia and preoperative fear. The patient might be cold, clammy, and feel ill for some moments afterwards. With spinal anaesthesia acute shock and collapse occurred. The speaker wondered whether the large bulk of dilute novocain solution injected in splanchnic anaesthesia might cause disturbance in liver function. During anaesthesia the Trendelenburg position was very favourable, whereas there was a real danger if the patient was on the face and the head raised.

Mr. BERNARD WARD thought there was no direct evidence against Crile's views on shock. Crile's kinetic theory was a very useful basis, and had profoundly modified the procedures used for prevention of shock. Nerve-block certainly minimised certain changes in the brain, liver, and adrenals, which otherwise followed trauma.

Prof. W. GEMMILL quoted cases of delayed shock. A boy playing football injured his humerus but continued to play, and after the game passed into profound shock. He believed the sympathetic nervous system tended to counteract shock.

The PRESIDENT wondered whether all the speakers had all spoken of the same condition. Were there

various syndromes of shock? In pneumonia or toxic scarlet fever a condition of circulatory failure simulating surgical shock was seen. He thought that a biochemical basis would eventually be discovered as the essential cause of shock. Fear might start the train of events but he doubted if it could initiate shock.

MANCHESTER MEDICAL SOCIETY

At a meeting of this society on Nov. 6th Mr. H. H. RAYNER spoke on the

Treatment of the Enlarged Prostate

After tracing the development of prostatectomy since its establishment as a practicable operation about 1901, he pointed out that little improvement had been made in the technique until the last few years, though better results had been obtained because preoperative preparation had improved through the whole period. Even to-day, however, in his anxiety to improve the renal function before operation by drainage of the bladder, the surgeon sometimes inflicted the grave handicap of sepsis on the patient by faulty methods in the use of the inlying catheter or by failure to recognise in time that a particular case is unsuited to this type of drainage. During the last ten years there had been considerable advances in the actual technique of treatment; there was perurethral resection on the one hand and the refinement of the open operation introduced by Harris on the other. Harris's operation had really eliminated the chief objections to open prostatectomy—uncertain control of hæmorrhage and sepsis. According to modern views of the mechanism of urination, the opening of the vesical meatus is accomplished by a pulling backwards of its posterior lip. If this lip was thickened or rigid the opening was likely to be obstructed, and this was the explanation of classical symptoms of prostatic obstruction occurring when the prostate is not enlarged. In the treatment of patients with this type of obstruction perurethral resection must be regarded as the treatment of choice, for it gave results as good as the open operation, with much less trouble to the patient. Most surgeons preferred the open operation of enucleation for the patient with gross enlargement of the prostate, for the results were more certain and the risk little if any greater. But with a very infirm or broken-down patient who had lasting retention a very limited resection of a large prostate often succeeded in restoring voluntary micturition, and though this benefit might be but temporary it was clearly preferable in such cases to a radical operation.

Open prostatectomy had received a great impetus from the Harris technique, the essential feature of which was the covering of the ragged walls of the prostatic cavity by the vesical mucous membrane. The advantages of this was assured hæmostasis without use of packing or bags; in consequence suprapubic drainage of the bladder after the operation was either dispensed with or employed for two or three days only with a fine-bore tube. Thus healing of the abdominal wound and restoration of natural micturition could be obtained within about a fortnight with considerable regularity. Mr. Rayner's experience of 19 such operations had led him to regard the method as standard and only to be departed from under exceptional conditions. Finally he pointed out that the personal attention of the surgeon and the services (almost whole-time) of an experienced nurse in the preparatory and after-treatment

were as important as the technique of the operation; hence, in great part, the striking disparity between the results of the operation in private and in hospital practice.

NEW INVENTIONS

FORCEPS FOR ESTABLISHING ABDOMINAL DRAINAGE BY COUNTER-INCISION

THE simple act of draining the abdomen through counter-incisions can sometimes become exasperating when we employ ordinary clamps or forceps. These makeshifts do not protect the finger, though we cut down on them blindly; they are poor targets for the knife, and rarely fit the hand that must open and close them amid coils of gut. It is not surprising then that fingers are hurt, and drains fail to pass through inadequate openings. The best makeshift is a short Lane's tissue-forceps, but the dangerous fenestrations discount the advantage of its wide extremity.

I have therefore had made for me a special forceps that serves—like a pistol—for either hand. The

large "butt" formed by the handles lies comfortably in the palm and does not project; the blades, representing the

barrel, make an obtuse angle with the "butt," and are wide enough when closed to cover

and shield the index-finger which points along them. Before cutting down through the abdominal wall on to the forceps, the tip of the index is slipped out from under the blades to feel for a spot free from gut on the parietal peritoneum. After finding the spot the finger can at once be replaced by the end of the forceps, which is grooved for the knife with a wide gutter, easily felt through skin and muscle. A spring keeps the blades apart, and when closed they overlap along their whole length so that there shall be no risk of the surgeon wounding his finger if he neglects to close them completely. The blades will not gape until the abdominal opening from which they emerge is large enough to admit a drain of average diameter. The pistol shape simplifies the excellent incision for posterior drainage advised by H. R. G. Poate in cholecystectomy (*Jour. Coll. Surgs., Australasia*, 1930, iii., 264) and, after interventions in the upper abdomen, a turn of the wrist will bring a suprapubic drain to the bottom of the pelvis.

I find that I can use this instrument safely with the complete assurance of drawing a tube into the abdomen at the first attempt. The instrument has been made for me by Messrs. Thackray Ltd. of Leeds.

REVIEWS AND NOTICES OF BOOKS

Great Doctors of the Nineteenth Century

By Sir WILLIAM HALE-WHITE, K.B.E., M.D., F.R.C.P., Consulting Physician to Guy's Hospital. London: Edward Arnold and Co. 1935. Pp. 325. 15s.

SINCE his retirement Sir William Hale-White has been spending some of his leisure pleasantly and profitably in writing a book and, as a true son of "Mark Rutherford," he has turned naturally to biography. The book contains 17 short biographies of great figures in nineteenth century medicine. The author's excellent method is to tell us first something about the man and secondly about what he did. Starting with Jenner, naturalist and country doctor, and ending with Sir Ronald Ross, poet and mathematician, we learn among many other things of the urbanity of Sir Astley Cooper and that Sir Charles Bell was not merely a great neurologist, but also a keen angler. Here is to be found an account of the life and work of that distinguished observer Richard Bright who, in addition to the disease which bears his name, first described chronic proliferative peritonitis and also Addison's disease (though he did not connect the latter with morbidity of the suprarenals). Others considered are Marshall Hall, who not only put an end to the practice of indiscriminate bleeding, but also gave us the theory of reflex action and a method of artificial respiration; Thomas Addison who, besides the two diseases called after him, first described appendicitis and inaugurated a system of case-taking by students at Guy's Hospital; Sir William Stokes, of the Stokes-Adams syndrome and Cheyne-Stokes respiration; Sir James Simpson, the obstetrician who introduced chloroform; and Sir James Paget, "the most successful man of his day," whose name, like those of Addison and Stokes, is associated with two distinct morbid conditions. Next come Sir William Bowman, histologist and ophthalmologist; Sir John Simon, the sanitarian who almost deduced the subsequent discovery of pathogenic organisms; Sir William Gull ("the physician in fashion though never the . . ."), famous for his work on . . .; and Sir Samuel Wilks, who not only demonstrated the visceral lesions of syphilis, but also rescued another's name from obscurity by putting Hodgkin's disease on the map. The remaining three articles deal with Lister, Hughlings Jackson, and Manson, names which could not properly be omitted from any such symposium. Naturally other famous figures cross the stage. Many receive more than passing notice from the author, and if most of his heroes are Guy's men none will blame him for his partiality. The reading is so agreeable that it is almost an impertinence to draw attention to certain eccentricities of punctuation or to the occasional harsh treatment of infinitives, but we feel sure that where "trite" is used on page 216, "terse" is really intended.

A book to be commended to doctors, laymen, and, above all, to medical students.

Tumours of the Urinary Bladder

By EDWIN BEER, M.D., F.A.C.S., Visiting Surgeon, Mount Sinai Hospital; Consulting Surgeon, Bellevue Hospital, New York City. London: Baillière, Tindall and Cox. 1935. Pp. 166. 16s.

THERE is no one better qualified to write on the treatment of bladder growths than Dr. Edwin Beer, for it was through his introduction of the high-

frequency current in 1910 as a means of treating vesical papilloma that this valuable therapeutic weapon was first made available to urologists. The present work is the outcome of 25 years' experience of bladder growths. During that time he has employed all the available methods of therapy, and in the work under review he seeks to estimate their value and to show which method of treatment is indicated in a particular case. Results have been analysed and a basis for comparison provided from the statistics of the Mount Sinai Hospital, where most of the work was done.

In Chapter 5 Dr. Beer points out that there are six main methods of therapy available in a case of bladder growth; transurethral electro-coagulation; transurethral introduction of radon seeds; suprapubic cystotomy with excision or open diathermy; suprapubic resection of the involved bladder wall; suprapubic total cystectomy; deep X ray therapy; and a combination of these various methods. Of deep X ray therapy, Dr. Beer has very little good to report. He has never seen a case cured by such means and regards it simply as a method of treatment for intractable hæmorrhage. In general his opinion of other methods of treatment harmonises with that voiced at the International Congress of Urology held in Brussels in 1927 and the French Urological Congress in 1932. Perhaps his view of the dangers and curative value of total cystectomy is less pessimistic than was that of the majority of surgeons speaking at these congresses, but it is only in matters of detail that his views differ from theirs.

The work is provided with the most complete bibliography of the literature of bladder growths that we have seen in any text-book. This bibliography takes up 26 pages and should prove of great value. The illustrations are excellent and include eight coloured plates.

Mucous and Salivary Gland Tumours

A Clinical Study with special reference to Radiotherapy, based on 254 cases treated at Radiumhemmet, Stockholm. By HUGO E. AHLBOM. Stockholm: Kungl. Boktryckeriet. P. A. Norstedt & Söner. 1935. Pp. 452. Swed. Cr.20.

DURING the years since the foundation of Radiumhemmet in Stockholm a number of monographs on malignant tumours have been published by the staff, and this latest addition takes a worthy place in the succession. Dr. Ahlbom begins with a careful review of the pathology of the tumours of the salivary glands; and the large number of references and very varied opinions quoted show that the question presents many difficulties. He accepts Ewing's view that the tumours are epithelial in origin, and the excellent illustrations of histological sections support this contention despite the rather misleading designation of fibro-myxo-chondro-epithelial tumour. The division into benign, semi-malignant, and malignant tumours would appear to be undesirable from the point of view of classification, though clinically it may be convenient. Much space is devoted to the discussion of the relation between the histological findings and the clinical symptoms. The experience gained from the treatment of 254 cases makes this section a striking reminder of the various lines along which these tumours, mostly of slow evolution, may develop, and the varied, and sometimes surprising, symptoms to which they may give rise. Differential

diagnosis is from tuberculosis, actinomycosis, inflammatory conditions, and salivary calculi, and between tumours of the histological types described. For this purpose a preliminary course of radiation may be used, the radio-sensitivity of the tumour giving an indication of its type. If biopsy is performed it should follow radiation, and the necessity of care in selecting the material for examination is emphasised.

The most interesting section is that on treatment. Surgical excision is still frequently chosen and follows the usual lines, complete removal of the capsule being considered essential. The diathermy knife may be used for excision, but more often the tumour with the surrounding tissue is coagulated by means of the endotherm and left to slough spontaneously. After surgical treatment, unless the tumour is benign, radium is inserted into the cavity, either immediately or later, but the wound is primarily sutured as far as possible. Tubes containing 25 mg. of radium of 15 to 20 mm. length and 3 mm. diameter are used, screened with a layer of 2 to 3 mm. of lead covered by a thin layer of dental compound so that the radium to tissue distance cannot be less than 4 to 5 mm. The radium is usually left in for 24 hours, but doses vary from 300 to 1800 milligramme hours, and are usually supplemented by external radiation. This may be given with Sievert's teleradium apparatus containing 3 grammes of radium with a skin distance of 6 cm. and filtered by 6 mm. of lead. 40 'gramme hours are given to one field in one to two weeks, producing a reaction of the order of epidermitis exsudativa.

Radiumhemmet has not yet accepted the r unit for radium dosage, preferring to express this as Imc hours, but the use of Sievert's condenser chambers allows of accurate measurement, and as the Imc bears a definite relation to the r unit (the latest figure given by Mayneord is one Sievert unit equals 8.3 r units) comparison with the doses given elsewhere is easy. With X ray therapy the method is "simple fractional radiation"; 200 to 600 r per day, measured on skin, are given, 10 by 10 or 10 by 12 being the usual size of field. The total dose per field is 3000 to 5000 r.

The results in "semi-malignant" tumours treated surgically show 17 per cent. of recurrence up to 5 years with 4 deaths in 32 cases; with the addition of radiotherapy there were no recurrences in 5 years. The uncertainty of the diagnosis, however, makes this of little significance. In the frankly malignant cases 25 per cent. of 93 cases survived 5 years, and some interesting statistics for the different methods of treatment are given.

Besides the microphotographs there are some excellent clinical photographs and paintings.

A Guide to Human Parasitology

For Medical Practitioners. Second edition. By D. B. BLACKLOCK, M.D. Edin., D.P.H. Lond., D.T.M. Liverp., Professor of Tropical Hygiene, Liverpool School of Tropical Medicine; and T. SOUTHWELL, D.Sc., Ph.D., A.R.C.Sc., F.Z.S., F.R.S.E., Walter Myers Lecturer in Parasitology, Liverpool School of Tropical Medicine. London: H. K. Lewis and Co., Ltd. 1935. Pp. 260. 12s. 6d.

THE authors of this book have done what they set out to do—namely, to give a clear account of the common pathogenic parasites of man in all climates, with descriptions of methods of diagnosis which are quickly learnt and easily carried out. They take

the reader over the care of the microscope and its use for examination and measurement; they discuss adequately the preparation of material; they describe protozoa, worms, and fly larvae in sufficient detail; and they give in addition one series of valuable tables on the diagnosis and spread of parasites, and another of diagrams which set out most clearly their life-histories. There are a few omissions, notably that of trichostrongylus infection, which is not uncommon; the failure to recognise its eggs has brought discredit to the doctor and depression to his patient. The unqualified statement is made that unfertile ascaris eggs are present because the host harbours only female worms; but the experience of G. F. Otto and of A. E. Keller over two large series of cases has been that unfertile eggs mixed with fertile ones are present in over 40 per cent. of cases. There is no mention of the large dorsal tooth of necator. The book is clearly written and well illustrated, and attention has only been drawn to a few matters needing revision in a third edition because of its general excellence and reliability.

The Psychology of Everyman

Nerves and the Masses. By DR. GEORGE DEVINE. London: Hutchinson and Co., Ltd. 1935. Pp. 319. 16s.

ASTONISHMENT is sometimes expressed that so much antagonism and distrust of medical psychology should be shown in certain orthodox quarters. This book serves in part to explain such an attitude towards what is actually a respected and established branch of medicine. Here are the over-confidence, the carelessness about evidence, the assertion of personal opinion, the mixture of knowledge and guesswork, the looseness of language, and the appeal to popular sentiment which antagonise serious doctors, and to which the subject still lends itself in the hands of enthusiasts. "Subconscious psychic force," for example, is here invoked to explain enfeeblement of the "Dormant Personality Unit"; as treatment "Mental Catharsis" is proposed, making use of the "Escape Mechanism"; conjoined with it is the exhibition of unspecified "Hormones" to help in "building up the nervous system of the psychoneurotic." If the book presented current teaching about mental disorder, using the term in the widest sense, then its far from sober style might be condoned; but many of its pronouncements cannot be reconciled with sound psychiatric opinion. Since there are already so many works which give trustworthy accounts of the present state of knowledge in this field, Dr. George Devine's book cannot be recommended.

Handbook of Bacteriology for Students and Practitioners of Medicine

Fourth edition. By JOSEPH W. BIGGER, M.D., Sc.D. Dub., F.R.C.P.I., D.P.H., Professor of Bacteriology and Preventive Medicine, University of Dublin. London: Baillière, Tindall and Cox. 1935. Pp. 458. 12s. 6d.

A NEW edition of this popular handbook issued three and a half years after its predecessor shows signs of extensive revision, though the size of the book has not been increased. No work on the subject covers more successfully the range of knowledge in bacteriology required from the student aiming at a qualification in medicine and the practitioner will find that it meets all his reasonable needs.

THE LANCET

LONDON: SATURDAY, DECEMBER 21, 1935

PLEURAL SHOCK AND/OR AIR EMBOLISM

Two bogies, remote but terrifying, attend on acupuncture of the thoracic wall. Dr. W. F. HAMILTON recently presented¹ to a combined meeting of the American and Canadian Medical Associations a careful analysis of 34,060 such punctures collected from American and German sources among which there were 112 accidents and 12 deaths. He excludes from this series a remarkable record² of M. BORSCH and D. WIDRÉ who made 13,932 punctures on 890 patients with only 12 accidents and no death. Sudden pain, even the touching of a part unused to touch, may, it seems, in rare instances cause syncope or sudden death, but, we may fairly presume, only in those whose constitutions are in a peculiar state. Fatal syncope has been recorded not only during pleural puncture, but even in such simple procedures as digital examination of the rectum. An editorial article in the issue of the Canadian journal containing Dr. HAMILTON's article states that pleural shock is rare, although not all the cases that occur are reported, while it quotes Dr. C. H. COCKE's reiterated opinion³ that air embolism is rare and pleural irritation relatively common as a cause of shock. Something may well depend on the technique. Done in the manner in which pleural puncture is sometimes performed—with blunt or turned instruments, badly made trocars and cannulas, failure to find the intercostal space leading to impact of steel on rib, neglect or imperfect use of local anaesthesia—it may well be that syncope sometimes occurs, and perhaps syncope is sometimes nearer death than we know. Yet there are those in this country who have punctured the chest thousands of times in all types of case and at all ages, without encountering serious shock; the careful clinician, aware of its possibility, endeavours to prevent it by employing every measure to prevent pain or sudden sensation. At the Victoria Park Hospital, where some five thousand refills are given each year, only one case of so-called pleural shock has occurred—and that not fatal. Novocain had been used but there was difficulty in finding the air space.

Air embolism, on the other hand, appears to be less uncommon in this country. Many instances have been recorded in which embolism was proved for certain by physical signs such as hemiplegia and by post-mortem demonstration. It is curious that it should not occur more often in inducing a pneumothorax. The fear of it led Prof. E. RIST to advocate oxygen for induction; but oxygen is not generally used for the purpose in this country,

doubtless because so few cases of air embolism are met with at this stage. It is rather during refills that the disaster occurs. There is no mystery, as a rule, about its mechanism. A pulmonary vein is punctured or lacerated; air enters from the instrument, from the pleural cavity, or possibly from the lung; it is drawn into the left heart, and then travels by the aorta to various destinations. If air embolism happens during a refill it must mean that either an adhesion or the lung itself has been punctured. This is one good reason for inducing local anaesthesia as a preliminary to every refill; not only to avoid pain and possible shock, but to make sure that there is an air space and a free air space. If a long slender needle is pushed gently into the pleural cavity, and air withdrawn through it into the syringe, it is practically impossible for air embolism to occur; whereas if the refill needle when inserted is attached to the tube of the apparatus there is nothing to prevent a considerable quantity of air being aspirated if its point should enter a branch of the pulmonary vein. What happens then is a question of chance. If a little air goes to a muscle, probably no symptoms are produced; if the same amount reaches the brain or the coronary arteries, serious symptoms will be produced. Larger quantities of air entering the pulmonary vein may cause death from disturbance of the heart's action when they reach the left chambers. Post mortem, however, it may be difficult or impossible to demonstrate small quantities of air in the coronary artery, and death is wrongly attributed to pleural shock. All this being borne in mind, in every case where there is or may be difficulty in finding the pneumothorax, the careful operator will introduce the refill needle on the end of a syringe. Air then cannot be drawn into a vein from the apparatus.

If as seems probable, owing to careful technique, both pleural shock and air embolism are now rare accidents of thoracic puncture, they may well be avoided altogether by still more careful technique.

TRICHOMONAS VAGINITIS

Of late years much more notice has been taken of the flagellate protozoon *Trichomonas vaginalis*. What does its presence in the vaginal secretion signify? Some authorities think the organism identical with its neighbour of the lower intestinal tract and also with the *T. buccalis* sometimes found in the mouth and the throat. The suggestion is therefore made that the vagina is infected from the anus—possibly in mechanical fashion through the custom of cleansing the anal region from behind forwards. On the other hand, it is quite certain that the trichomonas can dwell in the vagina without giving rise to symptoms and signs of infection. Hence it is often regarded as a normal vaginal inhabitant which may become pathogenic under abnormal circumstances.

Whatever the true aetiology, there is no doubt that the condition termed "trichomonas vaginitis" is a clinical entity with characteristic features. The onset is usually acute: the vaginal discharge

¹ Canad. Med. Assoc. Jour., October, 1935, p. 370.

² Beitr. z. Klin. d. Tub., 1928, lxi., 324.

³ Amer. Rev. Tub., 1931, xxiv., 545, and 1935, xxxi., 404.

is profuse, greenish-yellow, frothy, and malodorous. Vulvar itching and burning are common, and severe intertrigo of the skin of the vulva and thighs may develop. Clinically the picture is that of acute vaginitis, and examination of a fresh specimen of the discharge shows leucocytes, epithelial cells, bacteria, and large numbers of active flagellate protozoa. The question arises: why this sudden pathogenic activity on the part of an often harmless parasite? The answer most in favour is that something has happened to reduce the local immunity of the vaginal wall. HIBBERT¹ and HESSELTINE² have provided evidence that the additional element is infection by a non-hæmolytic streptococcus; indeed the latter thought the pathogenicity of *T. vaginalis* unproven and deemed it a scavenger which feeds upon bacteria. ALLEN, JENSEN, and WOOD³ now bring forward their reasons for believing that the vaginitis is due to symbiosis between a streptococcus and the trichomonas protozoan. They note that the symptoms vary considerably and that the typical clinical picture is not always seen. Symptoms referred to the bladder and the urethra—such as frequency, dysuria, nocturia, and even incontinence—may be so pronounced as to mask the vaginal source of the infection. This fact has already been emphasised by others, particularly by SAYER,⁴ who believes that the bladder forms the "residual habitat" of the parasite from which reinfestation of vagina and vulva occurs. ALLEN and his colleagues state that about a quarter of their patients develop menorrhagia, occasionally associated with metrorrhagia, and they attribute this to pelvic cellulitis resulting from upward spread of the streptococcal infection. The strains of streptococci which they were able to isolate from the vaginal secretions were of the green-producing type, and they were classified according to the curves of their electrical potential as estimated by their rate of movement towards the anode when in suspension in a cataphoretic cell through which an electric current was passed. In this way it was shown that their electrical grouping was different from that of streptococci isolated from the normal vagina and from the nasopharyngeal and tonsillar regions. The groupings of streptococci obtained from various infections with *T. vaginalis* were closely similar.

Examination of the male contacts of some of the patients gave interesting results. Seven showed evidence of chronic prostatitis and from the prostatic secretions a streptococcus was isolated which showed electrical reactions similar to those of the organisms obtained from the vagina. In six of the male contacts the trichomonas was actually recovered from the prostatic secretions, and in only three of those examined was it impossible to find either trichomonas or streptococcus. The investigators emphasise the regularity of this association of coccus and protozoan and regard sexual intercourse as the most likely means of

transferring the infection. They held that both trichomonas prostatitis and trichomonas vaginitis may well be added to the list of venereal diseases; and while these conclusions are not entirely acceptable on the evidence so far collected, it looks as though further investigations of this kind would soon make the nature of the infection much clearer.

CONTROL OF MYOPIA

THERE has been a growing tendency to take a somewhat fatalistic view of myopia and to belittle the influence of school hygiene on its incidence. Whatever view we may take of its causation, however—and without doubt the factors that play a part are various and differ in different cases—the belief doubted by some but still unrefuted holds the field, that prolonged application to close work by children and young adults with a tendency to myopia, acquired or inherited, leads to its increase. Among ophthalmic surgeons the share taken by excessive convergence in the causation of myopia is still in dispute. Mr. BISHOP HARMAN has no doubt of the harm done by prolonged close eye work, in susceptible children, or of the value of controlling eye work in myopes.¹ Sir JOHN PARSONS, on the other hand, doubts whether a reasonable amount of near work under good hygienic conditions does any harm to low myopes²; and there are some who believe that myopia is neither originated nor increased by near work.³ Those who argue in this way are fond of pointing to certain cases, or classes of cases, where the main cause of the origin or increase of myopia is certainly not near work—e.g., cases where the hereditary element is strong, cases of monocular myopia, myopia in such persons as agricultural labourers who have never been studious. There is also the so-called anterior myopia where the trouble lies not in a yielding sclera but in the cornea or the lens. No one maintains that prolonged convergence is the sole cause of myopia, but only that in the majority of cases, and especially in what is known as school myopia, excessive book work is an important contributing cause.

The mechanism of production is equally in dispute. In the middle of the nineteenth century DONDERs and his successors thought that prolonged accommodation weakens the resistance of the sclera to intraocular pressure; but this idea was proved to be fallacious. It was then argued that pressure of the external eye muscles and especially of the superior oblique, active in convergence, was the explanation; but this has never been proved. Dr. EDWARD JACKSON holds a somewhat different view⁴ of the mechanism of convergence in lengthening the axis of the myopic eye. The main obstacle to free movement of the eyeball, he points out, is the rigid optic nerve, firmly attached to the sclera. In convergence this resistance is constantly added to that of opposing muscles and other tissues. The forces

⁴ Jour. Amer. Med. Assoc., Nov. 2nd, 1935, p. 1412.

meet around the attachment of the optic nerve, but the effects produced on the temporal and nasal sides are different. On the nasal side the tissues are jambed together by the turning in of the eyeball, while on the temporal side of the nerve entrance they are stretched. It is on this side that ophthalmoscopic signs of progressive myopia are nearly always found, beginning with the typical myopic crescent and going on to choroidal disturbances between the disc and the macula. JACKSON'S hypothesis is at any rate plausible and is in accordance with the fundal changes in a great many cases. If it is true, the obvious necessity is to prescribe spectacles for constant wear which by correcting the myopia, together with any astigmatism present, put the eye in the same condition as that of an emmetropic eye—removing the temptation to undue convergence without interfering with the ordinary education. This is in fact the usual present-day practice. But it might be difficult to produce statistical justification for it. The steady increase of myopia during school life no longer counts as evidence, and some recent observations⁵ on

⁵ *Ibid.*, Oct. 26th, 1935, p. 1336.

the increase of myopia in Japan, where it is said to have more than doubled among school-children in the last twenty years during which time the strain of competitive examinations has continually grown, are similarly unconvincing. Dr. JACKSON himself sets out the results of full correction, drawn from 381 of his own private patients watched during a number of years, but obviously he could not check his results by comparison with a similar series of myopes treated by himself on a system in which he did not believe.

No one denies the influence of factors other than excessive convergence in the production of the myopic eye, but it so happens that excessive convergence can be corrected whereas the others cannot. With our present knowledge (or ignorance) it would be unwise to tamper with the principle on which most young myopes are now treated or to discourage efforts to secure special care for myopic children. Besides the wearing of fully correcting glasses this of course includes the correction of any faulty habits of posture that the child may have acquired, but not the attempt to limit the effort of accommodation required in ordinary life.

ANNOTATIONS

RICHET AND ANAPHYLAXIS

THE present age imposes specialisation and demands broadmindedness, and its motto may be said to be "live and let live," a comfortable but sometimes dangerous precept for the scientific research worker. The passing generation did not admit this philosophy; William Bayliss wrote, "my experience teaches me that it is better to hold a well-understood and intelligible opinion, even if it should turn out to be wrong, than to be content with a muddle-headed mixture of conflicting views, sometimes miscalled impartiality, and often no better than no opinion at all." The many-sided life of Charles Richet (of whom a biographical sketch appeared in our last issue, p. 1380) is one of the best examples of this point of view translated into tireless activity; wherever his interest rested, there it begat independent investigation. How many bacteriologists, even with the most catholic interests, would have thought of investigating the toxic properties of the tentacles of the sea-anemone? How many physiologists, having isolated the toxin, would have tested the power of a non-fatal dose to confer immunity to subsequent injections? Yet one has only to glance at the researches of Richet carried out during the last 25 years of the nineteenth century to realise that for him nothing would be more natural. It was not altogether accident which led to the surprising discovery that a fortnight after administration of the toxin a dog was not less but more sensitive to a subsequent dose. This phenomenon was described by Portier and Richet in 1902 and called *anaphylaxis* on account of its being apparently the reverse of immunity. The term has passed into general usage, but Richet lived to see the simple conception from which it sprang fade far into the background. Obviously connected in some way with immunity and allied phenomena, the subject aroused much interest and gave a new impetus to research; in 1912 Richet published a monograph "*L'Anaphylaxie*,"

and in 1913 he was awarded the Nobel prize for medicine. In spite of the enormous amount of work which has been done since then, no theory has been entirely successful in explaining the fundamental reason why the second injection of a foreign protein should cause anaphylactic shock, but the side issues which have been raised have proved fruitful in many directions. Whatever the explanation ultimately accepted, it must also account for, or help to account for, other manifestations of hypersensitivity, from the tuberculin and similar reactions to everyday afflictions such as urticaria, asthma, and hay-fever, and its precise relation to the phenomena of immunity must be revealed.

RECOVERY FROM CORROSIVE POISONING

LAST year Prof. H. Salzer of Vienna published a paper¹ on corrosive burns of the oesophagus and their early treatment by dilatation. In support of such early treatment he stated that 163 of his 180 cases terminated in recovery. This paper has now drawn a well-documented answer and criticism² from Prof. S. Bélinoff of Sofia. During the past five years he has treated an average of 55 cases of corrosive oesophagitis every year; 170 of his 274 cases were acute, the rest were chronic. The 170 acute cases were classified in three groups, according as they were (1) so slight as not to require treatment, (2) so severe that they were fatal before treatment could be instituted, and (3) of moderate severity. The number of cases in these groups was 18, 46, and 106 respectively. If only the 106 patients who received treatment be considered, recovery or improvement could be claimed in 73 per cent., while the mortality was 23 per cent. Salzer's recovery-rate of 89 per cent. must be considered in the light of the fact that all his patients were children, whereas only 20 of Bélinoff's were children under the age

¹ *Wien. med. Woch.*, June 30th, 1934, p. 736.

² *Presse méd.*, Oct. 9th, 1935, p. 1564.

of 15. Now there is a good deal of difference between the corrosive poisoning of children and that of adults. The former take corrosives by accident, spitting them out promptly, and seldom swallowing much. The corrosive poisoning of adults is usually an attempt at suicide, large quantities of corrosive being swallowed, and the resulting burns are comparatively severe. The œsophagus of a child is more elastic than is the adult œsophagus, and the natural growth may widen the lumen; this again is a factor affecting prognosis. Bélinoff, who does not begin to dilate the œsophagus till some seven to ten days after a burn, and who uses apparatus specially designed for the purpose, pleads for the use of a common denominator when the merits of various methods of treatment are compared. Before any claim can be made on behalf of some treatment or other, the claimant must state the age of his patients and classify them according to the severity of their burns. If he does this and eliminates the patients requiring no treatment and those who die before any treatment can be given, he should have a uniform residuum *where-with to compare his therapeutic achievements with those of other observers.*

CORYZA AIGU BANAL

THAT when there are many remedies there is no cure is now a proverb; that doctors cannot cure a cold is a gibe to which we have grown accustomed, if not resigned. In an unusual spirit of optimism the editors of the *Vie médicale* devote their latest symposium¹ to the evergreen problem of coryza. Twenty-two distinguished physicians and laryngologists give their views on the subject; but alas their wide diversity neither refutes the proverb, nor provides an effective retort to the gibe. Dr. P. Aubriot, of Nancy, divides the common cold into two phases, the vasomotor and the infective. It is only in the former, and shorter, phase that treatment may abort the disease. He advocates the use of pilocarpine but does not disclose how, when, or in what dose it is to be given. While not denying the importance of microbic infection and its transmissibility by sneezing, coughing, and so forth, he considers that "only those with pituitaries which are sensitive owing to habitual or transient vasomotor instability" will develop the disease. Dr. J. Barataux recommends, among other measures, the Chinese treatment called *Ko-kou*, which consists in thrusting a needle several millimetres deep into the dorsum of the hand between the thumb and index-finger. Which hand is not specified; nor is it stated whether the doctor's tongue should be in his cheek whilst carrying out this procedure. Many of the contributors regard prophylaxis as the better part of therapy. Thus, Dr. Carréga, of Marseilles, bids us avoid carriers—a counsel of perfection indeed. Dr. Labarrière would have us avoid draughts and cold feet, while Dr. Debidour believes in cold baths and in accustoming the body to cold, a belief shared by Drs. J. Tarneaud and J. Vialle. Again, while Dr. Vialle would "combat endocrine dysfunction," Dr. A. Soulas would "treat the general condition." Dr. Berger likes vaccines, and the correction of nasal deformities is supported by Drs. G. Toitot, A. Bloch, Soulas, and Tarneaud, all of whom, *mirabile dictu*, are oto-rhino-laryngologists. As to drugs, for both local and general use, their name is legion. Ephedrine, adrenaline (with or without storaine), aconite, belladonna, silver salts, magnesium chloride, and urotropine all have their champions. "Purge first" is the

advice of Drs. Jacques and Bloch. Dr. Rachewsky gives morphia; Dr. Jacod, opium. Quinine has two votes; the salicylates three. Menthol is curiously unpopular; Dr. Batier finds that it "provokes reactive congestion," and Drs. Debidour and Leroux-Robert that "it is a generator of laryngeal spasm." Diathermy, infra-red rays, and antiviral therapy are also mentioned. Dr. Leroux-Robert has heard of a way of aborting a cold by inhaling a mixture of equal parts of ammonia, tincture of iodine, carbolic acid and alcohol but "does not know the result of this method." It is with relief that we are able to record that none advocates the wearing of an iodine locket, the hanging of garlic outside the bedroom window, or the draping of the counterpane with a string of onions. After reading the symposium, we are forced to the conclusion that the treatment of the common cold is not one of the many things they order better in France.

OBSessional ILLNESS

PSYCHOPATHOLOGY has received much more attention of late years than any other aspect of neurosis; it has sometimes seemed as though no other aspect was thought deserving of attention. In a paper on the problem of obsessional illness, read before the psychiatric section of the Royal Society of Medicine on Dec. 10th, Dr. Aubrey Lewis indicated the wider range of questions raised by one of the typical neuroses. He pointed out that in the causation of the symptom it was usually possible to discover the mechanism determining the content of an obsession in any individual case, but that these mechanisms were not limited to obsessional illness nor characteristic of it. To go further, one might with the Freudians take certain unprovable premises—Freud had himself called the theory of instincts a mythology—but one could not at present elucidate the special psychopathology of this disorder otherwise than speculatively. The ways in which at various stages of life the obsessional tendencies had manifested themselves was an object of study which had been little pursued, especially in normal persons. The character usually described as obsessional was not infrequently found in those who developed other types of mental illness. The relationship of obsessional neurosis to melancholia and schizophrenia was a frequent observation, which had been little reckoned with. Still more complicated was the issue raised by the occurrence of obsessions after an attack of encephalitis lethargica in persons who had been free from any such traits beforehand. A purely psychological interpretation was here impossible; one had to consider the influence of motor disorders on the structure of the personality as well as the specific cerebral damage, though one would avoid crude efforts at localisation of function.

In any approach to the problem of causation, the psychiatrist is being pushed back to constitution, or, more strictly, heredity as the indispensable factor. In a detailed study of the families of 50 obsessional patients, Dr. Lewis found pronounced obsessional traits to be widespread among the parents and siblings; such data could not, however, be evaluated without comparable investigation of the average population and others. Twins would provide valuable information, but the number of cases was still too small. Prognosis and treatment are generally regarded with much gloom; nothing but psychoanalysis lasting for years can, in the opinion of some, do any permanent good. In order to find out what grounds there might be for such pessimism, Dr. Lewis took 50 patients from the records of the Maudsley

¹ *Vie méd.*, Oct. 25th, p. 891.

Hospital and pursued inquiries into their subsequent history, which covered from five to ten years. These patients were a fair sample of obsessionals taken at random; various forms of treatment, including intensive psychotherapy, had been used. Two of the patients had come only once to the hospital and had no subsequent treatment: one of them was now much worse, the other had been quite well for ten years. Half the patients had been well for five years or more; some others had been well for years but had had a recurrence from which again they recovered. The results did not prove any better outcome from one mode of treatment than from another: many factors entered into this, and in some cases it seemed clearly to be external circumstances that had effected a change. In one case, obsessional symptoms which had been very severe disappeared entirely during the war, to return afterwards. The findings did not indicate that psycho-analysis was the treatment of choice; in many instances it would have been superfluous and unwarranted.

For the prospect of recovery Dr. Lewis finds neither the content of the obsessions nor the patient's age to be the ruling factor. The likelihood of an obsessional patient carrying his impulses into action, and so coming into conflict with society, is small. Suicidal attempts happen because the patient is also depressed; they are seldom the expression of an uncontrollable obsessional impulse. Murder and sexual offences cannot be included in the category of obsessional actions; there were essential differences clinically and psychologically. In his concluding remarks Dr. Lewis emphasised the need for detailed clinical study if the problem of obsessional illness is to be solved.

INTERVAL BETWEEN PRIMARY AND LATER MANIFESTATIONS OF TUBERCULOSIS

Prof. Arvid Wallgren, whose studies of erythema nodosum and tuberculosis in Göteborg have been conducted over many years, has now, with Dr. A. Lundblom,¹ tried to estimate the average interval between the first manifestation of a tuberculous infection (erythema nodosum) and three later manifestations—namely, meningitis, pleurisy, and tuberculosis of the bones. Wallgren's earlier investigations have shown that the incubation period of tuberculosis—i.e., the interval between infection and the appearance of erythema nodosum—is between three and eight weeks, usually between five and six. In a series of 111 cases of serous pleurisy preceded by erythema nodosum it was found that the interval between the appearance of these two conditions was usually 3–6 months. In 64 cases of tuberculous meningitis preceded by erythema nodosum the interval between the two was usually less than three months. These observations suggest that the chances of erythema nodosum being followed by tuberculous meningitis diminish rapidly three months after the appearance of the erythema, and that the chances of pleurisy diminish after the sixth month. The child who develops tuberculous pleurisy as a sequel to erythema nodosum is, therefore, almost out of the wood so far as the chances of developing tuberculous meningitis are concerned. In support of this calculation it is noted that in a children's hospital in Göteborg, in which 400 children have been treated for pleurisy since 1922, only 2 have subsequently developed tuberculous meningitis. In cooperation with the staffs of other Swedish hospitals, Wallgren and

Lundblom have now extended their studies to tuberculosis of the bones; and in 115 such cases they find that the interval between the onset of erythema nodosum and the first signs of tuberculosis of the bones and joints was a year or less in about half, two years or less in about three-quarters, and under three years in almost all. In other words, the child who develops erythema nodosum is not likely to develop meningitis if he has not done so within three months, pleurisy if he has not done so within six months, or tuberculosis of the bones and joints if he has not done so within three years. The survey ends with a study of 2031 cases of tuberculosis of the bones and joints which shows that this condition usually comes on between the ages of 6 and 30, the highest rates being between the ages of 16 and 25 when the opportunities for infection are greatest.

JOHN WHITRIDGE WILLIAMS

"Ease, grace, and dignity were the symbols of his habitual self-control. He seemed to do as he liked without restraint, confusion, or awkwardness." Dr. Morris Slemons has chosen these words from Hazlitt's essay on the "Look of a Gentleman" to describe John Whitridge Williams, to whose work and personality he paid tribute in a presidential address to the Pacific Coast Society of Obstetrics and Gynecology on Nov. 9th. The lecture has now been published in book form,¹ and as the story of Williams's career as obstetrician and administrator is also the story of the department of obstetrics and of the introduction of a system of whole-time teachers at the Johns Hopkins Hospital, it has a general as well as a personal interest. Williams served the hospital for over 40 years, being appointed associate professor of obstetrics in 1896 and professor in 1899. He was twice offered high positions in other cities, but each time he was persuaded to remain, once by the establishment of obstetrics as a whole-time department and once by the founding of the Women's Clinic. At the Johns Hopkins Hospital circumstances had made the separation of obstetrics from gynaecology inevitable, but in an interesting discussion of the system Dr. Slemons makes it clear that Williams himself did not approve of it. A bibliography of Williams's writings up to his death in 1931 is supplied, and his work on the investigation of the problems of placentation, the funnel pelvis, and prenatal care is discussed in some detail.

THE NERVOUS FACTOR IN DECALCIFICATION

Mario Coppo² thinks that the possibility of a nervous control of calcium metabolism in bone has been too summarily dismissed—notably by Leriche and Policard. He himself believes that such control exists, and he visualises the responsible nerve-fibres as leaving the spinal cord by the lateral horns in company with others having a trophic function. He argues that such regulation of metabolism is in line with the nervous control already suggested for glycogen-glucose equilibrium, and for the trophic changes in muscular and adipose tissues. The factors predisposing to, or determining, decalcification of bone he divides into general and local. Under the former heading he lists such conditions as hyperparathyroidism, deficiency of vitamin D, obesity, and (doubtfully) acidosis. Under local causes he includes immobilisation and tuberculosis of bones and joints.

¹ John Whitridge Williams. Baltimore: The Johns Hopkins Press, 1935. Pp. 109. 7s.

² Paris méd., 1935, xxx., 110.

¹ Nord. med. tidskr., Oct. 26th, 1935, p. 1699.

Looking for a single underlying cause, Coppo finds it in the nervous factor: decalcification, in fact, he regards as a trophic phenomenon. In support of this he relates the results of experiments in which he estimated the mineral content of bone previously submitted *in situ* to the action of ischaemia, stasis, nerve section, immobilisation, and the proximity of an abscess. Nerve section, he says, led to definite and constant mineral loss within 10-15 days, whereas none of the other factors, operating over the same period, had any effect on the mineral content of the bone. The conclusion drawn is that the nervous factor is alone of importance, and that all other causes of decalcification act through their influence on the trophic nerves. This sweeping generalisation, however, will not be readily accepted; for there are reports by other workers to the contrary.

THE CALCULATION OF BASAL METABOLIC RATE

Dr. T. J. F. Frank, of Melbourne, has recently made an exhaustive and impartial investigation into the claims of three formulæ for the estimation of basal metabolic rate (B.M.R.) on the basis of pulse-rate and pulse-pressure values.¹ In 250 patients he has compared the result obtained from gasometric analysis with those calculated from the formulæ, and has shown that the latter are extremely inaccurate. The danger of using them for diagnostic purposes is emphasised by the inclusion of 43 patients who had complaints which left the basal metabolic rate unaffected, but which simulated thyroid disease in various ways. In 17 of these patients the calculated B.M.R. differed by more than 20 per cent. from the normal, and in some of them might well have led to a false diagnosis of hyperthyroidism and to surgical treatment. The remaining 207 patients mostly suffered from various forms of hyperthyroidism, but included 5 cases of hypothyroidism. Dr. Frank has tabulated his results according to the pathology of the complaints, and has regrouped them on the basis of the degree to which the B.M.R. (as measured gasometrically) was raised. In no group, classified by either of these methods, is there any striking agreement between the formulæ and gasometric determinations. The former are no safer in either slight or severe cases, whatever the basis of diagnosis. There is rather more to be said for the formulæ as giving comparative results in the same patient, and in some cases, if a preliminary gasometric determination is made simultaneously with pulse and blood-pressure readings so as to estimate the disparity between the two methods, the patient's progress may be followed roughly by periodic calculations from the formulæ. This is by no means always true, and the figures given for 6 cases followed by Dr. Frank are not encouraging. It may be contended that the gasometric method itself is not very accurate under clinical conditions, but the error here lies in the actual determination and can be minimised by employing an expert to make it and by insisting as rigorously as possible on the maintenance of basal conditions. The theory of the method is rational, and although it has not escaped criticism, notably by E. P. Poulton,² it is unlikely to be modified to an extent which would interfere with the usual interpretation of the results obtained in practice. The formulæ, on the other hand, are quite empirical and lack any theoretical background. Moreover, three measurements have to be made—pulse-rate, and

systolic and diastolic blood pressure—and each of these is subject to error. It is clear that the procedure as well as the theory of using such formulæ have very little to recommend it, and it is perhaps unfortunate that it is so easy to carry out. Dr. Frank, like most experienced clinicians, emphasises the importance of giving full value to clinical observations as well as to the basal metabolic rate in estimating the severity of thyroid disease.

INTERNATIONAL LEAGUE AGAINST EPILEPSY

DURING the International Neurological Congress held in London last summer a number of those particularly interested in epilepsy met at the Lingfield epileptic colony: 32 doctors representing 14 countries. After discussion it was unanimously decided to revive the International League against Epilepsy with a view of improving the social condition and institutional care of sufferers from epilepsy. It was agreed to issue a publication, annually or oftener, acquainting readers with facilities and with remedial efforts carried on in various countries. Plans were also laid for the league to meet during the next neurological congress in Copenhagen. At a later meeting, Prof. A. Ley of Brussels being in the chair, the following officers were elected: president, William G. Lennox, Boston, U.S.A.; treasurer, Tylor Fox, Lingfield, Surrey; secretaries, H. I. Schou, Dianalund, Denmark, and L. J. J. Muskens, Amsterdam. All who are interested in improving the condition of epileptics are invited to join the league. The membership fee, which includes subscription to the periodical, is the equivalent of 5s. a year, or 15s. for the four-year period.

RESPIRATORY DISEASE IN NEW-BORN INFANTS

ALTHOUGH pneumonia and atelectasis are generally recognised as important causes of death in the newly born, they have mostly been investigated from the pathological rather than the clinical standpoint. It is useful therefore to have Dr. W. S. Craig's account¹ of his observations in the Royal Maternity Hospital, Edinburgh, where he has made a study of all those infants showing disturbance of general health, and has correlated the clinical and pathological findings in 146 cases coming to autopsy. Radiography was not employed, so that the conditions correspond to those of ordinary practice. In 60 cases no signs of pulmonary disease were found on physical examination; at autopsy, the lungs appeared normal in 52 of these, while 8 showed extensive atelectasis. Consolidation was diagnosed clinically in 50; of these, 28 showed pneumonia, 8 pneumonia with hæmorrhage, 12 hæmorrhage without inflammatory changes, and 2 pleurisy without pneumonia. Atelectasis was diagnosed in 24, and was found in uncomplicated form in 20 of them, in 1 where consolidation had been suspected, and in the 8 cases already mentioned, in which no physical signs had been found. Uncomplicated bronchitis was present in only 4. Analysing the clinical findings, Craig first groups together those cases in which pneumonia or hæmorrhage, or both, produced consolidation. In these he found that the most common sign was cyanosis, which was not so deep as that due to subdural hæmorrhage and responded more readily to oxygen administration. Feebleness at birth, or shortly afterwards, due to prematurity or difficult delivery was noted in the majority. Cough was rare, and the *aké nasi* were only seen in action shortly

¹ Med. Jour. Austral., Sept. 30th, 1935, p. 397.

² See THE LANCET, 1934, I, 197.

before death. The temperature chart was not typical, the temperature being irregularly raised or subnormal. Respiration was rapid, at first deep and subsequently shallow, and sometimes there was retraction of the intercostal or upper abdominal muscles during inspiration. Percussion of the chest was seldom of any help in diagnosing consolidation and the breath sounds were not typically bronchial. Crepitations, however, were constantly present, and were sharp and crackling, localised at the bases or in the axillæ and heard only at the end of inspiration. The physical signs in the cases where bronchitis was later found at autopsy were similar to those noted in cases of consolidation, except that cyanosis was always present and cough commoner; rhonchi and coarse bubbling râles were heard on auscultation. There were 8 recoveries among cases in which bronchitis was diagnosed. Atelectasis was characterised clinically by general limpness, a tendency for the temperature to be subnormal, a variable tinge of cyanosis uninfluenced by oxygen administration, and rapidity but no embarrassment of respiration. The physical signs were less definite than in other conditions described, the breath sounds being distant and often jerky, with no accompaniments. Craig emphasises the tendency for respiratory disease to occur in premature and asphyxiated infants, and its frequent association with intracranial hemorrhage. The speed with which pneumonia proves fatal in the newly born is shown by his figures: of the 56 cases with consolidation, 51 died within three days and 2 within six days of the condition being recognised.

HEMOLYTIC ANÆMIAS

"HEMOLYTIC anæmia appears in many guises: between acholuric jaundice and the acute type described by Lederer we may recognise an ascending series of anæmias." These are the opening words of an instructive paper by Dr. J. L. Lovibond which we publish this week. How far, it may be asked, is his conception of hemolytic anæmias valuable in practice? Acholuric jaundice is a clearly defined clinical and pathological entity. It is a hereditary condition characterised by increased spherocytosis, reticulocytosis, and fragility of the red cells associated with splenomegaly and a positive indirect van den Bergh reaction. These abnormalities may give rise to no symptoms, being recognised only when a careful examination is made, or they may result in either a chronic or acute form of anæmia. The acute hemolytic anæmia of Lederer, on the other hand, presents a very ill-defined clinical and pathological picture. Before casting aside the diagnosis of a definite disease such as acholuric jaundice for an indefinite condition like "acute hemolytic anæmia," it is essential that in any particular case red cell fragility determinations should be made by an accurate quantitative technique both upon the patient's blood and upon that of his relations though they claim to have excellent health. A survey of recently reported cases suggests that if such investigations are carried out acholuric jaundice is the final diagnosis (Scott,¹ Murray-Lyon²). Four cases described by Joules and Masterman³ cannot be accepted as proved not to have acholuric jaundice; other members of the family were not examined and in at least one patient fragility was increased. Since Doan, Curtis, and Wiseman⁴ have brought forward

conclusive evidence that splenectomy is indicated even in acute cases of acholuric jaundice, the necessity of making an accurate diagnosis in hemolytic anæmias is not only of academic but also of immediate practical importance.

A FOOD POLICY

THE report drawn up by the Expert Commission on Nutrition, which met in London under the chairmanship of Prof. Edward Mellanby last month, has now been issued, and we are able to reproduce its essential features on a later page. The report is itself a landmark, but it is only the first stage of the Commission's work. Since the general principles laid down in it are to be applied in different countries and must therefore be adapted to varying conditions of population, customs, and social life, the report is now to be communicated for study to representative scientific institutions in those countries. They in turn will collect advice from technical experts—clinicians, pædiatricians, school medical officers, and the like—and this advice will be analysed and summarised by the Commission and will then be placed at the disposal of a special committee appointed by the League of Nations Council. In this country the advisory body is the Medical Research Council, in the U.S.A. the National Research Council, and in France the Academy of Medicine. In the meanwhile all who are interested in the initiation of a comprehensive national food policy will study the report and, if they are wise, supplement this study by reading the remarkable survey issued¹ in the summer by Dr. E. Burnet and Dr. W. R. Aykroyd, two officers of the League's Health Organisation.

WE regret to announce the death last Monday of Mr. Frank Chetwode Crawley, formerly President of the Royal College of Surgeons in Ireland.

WHO'S WHO for 1936 contains some 40,000 biographies of men and women of the time arranged in convenient form and, for the most part at all events, certified by their eponyms. This is the 88th year of issue of a book of reference which becomes every year more indispensable. Those who would save themselves trouble and anxiety will also procure the two companion volumes, "Who was Who," 1897-1915 and 1916-1928. Year by year names drop out of "Who's Who" on account of death; when details of these biographies are afterwards required much search may be needed unless the actual year of death is known. The prices of the volumes are I., 60s., and II. and III., 21s. each, from Messrs. A. and C. Black Ltd.

MR. FRED BUTTERFIELD, who died in London on Dec. 14th at the age of 67 years, had been for more than forty years secretary of the Incorporated Dental Society. When the Dental Board of the United Kingdom was set up in 1921 Mr. Butterfield was appointed by the Privy Council to represent the practising dentists registered under the 1921 Act without diploma, and three years later he was elected to the Board by the free vote of these dentists. On the Dental Board he did all he could to further the interests of the dental practitioner and he served on four of its committees, including the discipline committee and the education committee. His colleague, Mr. W. L. Edwards, representing dental practitioners, died suddenly in April of this year.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXI.—PROGNOSIS IN MALIGNANT GROWTHS OF THE TESTICLE

VARIOUS classifications and descriptions of malignant growths of the testicle have at times been given and the subject has led to a good deal of controversy. For clinical purposes however, it is sufficient to divide them into two big classes: (1) seminomas or spermatocytomas arising from differentiated germinal epithelium, and (2) embryomas or teratomas arising from undifferentiated germ cells. No further subdivision of the seminomas is necessary, but embryomas or teratomas can be again separated according to their gross or microscopic characteristics, into dermoids, mixed tumours, chorionic carcinomas, and the various types of carcinoma and sarcoma which may be developed within a pre-existing teratoma. From the clinical point of view it may be said that the chief points which distinguish the seminoma from the teratomatous tumours are that the former develop at a later period of life and do not so readily form metastases. The prognosis is therefore better in the case of a seminoma than in that of a teratoma.

Although the outlook is slightly better for a patient who has developed a seminoma than for one who has a teratoma, it must be realised that all malignant growths of the testicle have a high degree of malignancy. The prognosis will therefore depend on the date at which the trouble is discovered and the completeness of the measures taken for its eradication. It is an unfortunate fact that because malignant growths of the testicle are comparatively rare (Russell Howard found 65 cases in 110,000 male cases admitted to the London Hospital) a new growth is seldom suspected before the risk of dissemination has occurred. For this reason L. Chevassu, who has had a unique experience in the treatment of malignant testicle, urges that the organ should be explored under an anæsthetic whenever a hard area has been detected in a testis that otherwise appears to be normal. The earliest sign that may be discovered at such an exploration is an unusual vascularisation of the tunica albuginea in the region of the induration, and this alone should be sufficient in the absence of any explanation to entail immediate orchidectomy.

Experience has definitely proved that simple orchidectomy fails as a means of cure. Chevassu collected statistics from 100 cases in which removal of the testicle alone had been performed and found 19 cures and 81 deaths. Of the 19 cures, 13 were alive and well from 4-7 years and 6 from 7-10 years after operation. Of the 81 who died 47 per cent. were dead within a year of operation. Simple orchidectomy is even more irrational than simple removal of the breast in mammary carcinoma, since the lymphatic spread is more rapid in the case of malignant disease of the testicle than in that of malignant disease of the breast. As a supplementary measure to orchidectomy two means of dealing with secondary deposits are possible: (1) removal of the testicle together with the whole of the lymphatic field as far up as the renal veins, and (2) orchidectomy followed by deep X ray therapy.

ORCHIDECTOMY WITH SURGICAL EXTIRPATION OF THE LYMPHATIC FIELD

The operation is a severe one and carries with it a definite operative mortality that is probably in the region of 10 per cent. Frank Hinman (1935), in report-

ing on 9 cases in which he carried out removal of the testicle, together with its lymphatic field, states that amongst the 8 who survived operation 2 died of metastases at 9 and 18 months respectively, and another at 4½ years. H. H. Young (1926) states that in another 8 cases, 4 survived, one being alive 9 years later, one 4½ years, and 2 one year after operation. Of the 4 who did not survive even for so long a period as a year, 3 died with regional metastases.

ORCHIDECTOMY AND DEEP X RAY THERAPY

Deep X ray therapy may be begun a week or ten days after the operation or the testicle may be irradiated before its removal. According to most authorities the latter plan is preferable, since it reduces the chances of malignant cells being liberated at the time of operation. As, however, in many cases the diagnosis can only be confirmed by exploration, X ray therapy is more commonly carried out as a secondary procedure. A. L. Dean, reporting on teratoid tumours of the testis treated by X rays of high voltage, states that out of 7 patients with operable tumours 5 remained free from all signs of disease, whilst of the 49 patients who were first seen with inoperable metastases, only 5 were free from signs of disease after treatment. In his opinion pre-operative irradiation of the primary tumour is highly desirable, his results showing a much lower mortality in patients so treated. Although the number of cases treated by orchidectomy and deep X ray therapy in my practice has been small, I am able to report patients living free from recurrence at the end of 8, 7, 6, 3, and 2 years respectively. In one of these there already existed a large mass in the left hypochondrium when X ray treatment was started. This mass rapidly disappeared a few weeks after Dr. N. S. Finzi had instituted treatment, and the patient remains alive and well six years later. Dr. Finzi has reported to me that he treated a case of malignant testicle with a secondary mass in front of the rectum 25 years ago, and that he believes this patient to be alive at the present time. But in spite of these successes with secondary deposits, it is an undoubted fact that the prognosis is always better when deep X ray therapy is started before secondary lesions are apparent. The prognosis of later recurrences occurring subsequent to the deep X ray therapy is undoubtedly bad, such recurrences proving to be more radio-resistant than those that may previously have been dealt with.

Although surgeons have not yet reached unanimity on the subject, the majority are of the opinion that the results of deep X ray therapy are better than those obtained from surgical extirpation of the lymphatic field, and H. Cairns has even gone so far as to state that after an analysis of 43 cases in which simple orchidectomy was performed and of 17 who were subjected to the radical operation, it seems to him questionable whether the latter offered enough to justify the risk it entailed.

SUMMARY.—The prognosis of malignant disease of the testicle may therefore be said to depend on the following factors: (1) histological characteristics of the growth; (2) date at which it is discovered; (3) the presence or absence of secondary deposits; (4) the intensity and thoroughness of the X ray treatment.

KENNETH M. WALKER, F.R.C.S.,

Surgeon to the Genito-urinary Department, Royal Northern Hospital; Surgeon to St. Paul's Hospital.

SPECIAL ARTICLES

GENERAL MEDICAL COUNCIL

WINTER SESSION, NOV. 26TH-DEC. 3RD

SECOND REPORT FROM THE CURRICULUM COMMITTEE

THE Curriculum Committee, G.M.C., was appointed in June, 1934, to consider the information and proposals received in respect of the revision of the curriculum. This committee, of which Dr. H. L. Tidy is the chairman, reported to the Council on May 31st, 1935, and it was resolved that the documents should be circulated to the licensing bodies and the deans of the medical schools for their observations, when the whole matter would be further considered at the next November session. A full abstract of the recommendations forming the first or interim report was published in our columns, the resolutions being given verbatim (see THE LANCET, June 15th, 1935, p. 1403).

A second interim report was received by the G.M.C. at its recent winter session, and in this document the provisional views of the Curriculum Committee on the important points are set out, with the alterations in accordance with suggestions received. It will be convenient to readers to have before them the text of the later report, although so much of it has been substantially published in our columns recently. The alterations are printed in italics. It is recommended that every student should be registered at the commencement of his studies in the Medical Students' Register.

I.—Pre-Registration Examinations

Before registration as a student or commencement of the medical curriculum proper every person shall be required to pass, in addition to an approved preliminary examination in general education, an examination or examinations conducted or recognised by one of the licensing bodies, and comprising the following subjects:—

1. One or two subjects of general education at an approved standard.

2. Chemistry (theoretical and practical), the elementary principles of the chemical combination of elements, including carbon.

3. Physics (theoretical and practical), the elementary mechanics of solids and fluids, the elements of heat, light, sound, electricity, and magnetism.

4. *Elements of General Biology: A course of instruction, including practical work, in the fundamental facts of vegetable and animal structure, life-history, and function; and an introduction to the study of embryology.*

The examination in the subject of biology may be taken after registration as a student in the period of study of the professional scientific subjects.

II.—Medical Curriculum

With regard to the course of study and examinations which persons desirous of qualifying for the medical profession shall go through in order that they may become possessed of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery, the Council recommend as follows, viz.:—

The period of professional study, between the date of registration as a medical student and the date of the final examination for any diploma which entitles its holder to be registered under the Medical Acts, should be a period of certified study during not less than five academic years.

The first two years should be devoted to the study of professional scientific subjects with an intro-

duction to clinical subjects. The last three years should be devoted to the study of the clinical subjects together with the clinical application of the professional scientific subjects.

Throughout the whole period of study, the attention of the student should be directed by his teachers (a) to the importance of the measures by which normal health may be assessed and maintained, and (b) to the principles and practice of the prevention of disease.

In every course of professional study, and in the examinations, the following subjects should be included:—

A.—PERIOD OF STUDY OF THE PROFESSIONAL SCIENTIFIC SUBJECTS (FIRST AND SECOND YEARS)

1. Human Anatomy and Human Physiology: These courses should include:—

- (1) Dissection of the entire cadaver.
- (2) Anatomy of the living body.
- (3) Elements of human embryology.
- (4) *Histology, the elements of cytology.*
- (5) *The elements of genetics.*

NOTE.—This subject may be taken with Biology.

(6) The principles of general physiology, the chemistry and physics of bodily functions studied as far as possible in the human subject.

(7) *Instruction in normal reactions of the body to injury and infection as an introduction to general pathology and bacteriology.*

(8) Elements of normal psychology.

Instruction, illustrative of that given in anatomy and physiology and introductory to later studies, should be given in the second year in the following subjects, the amount of time to be allotted to them not to exceed one-third of the total time available in that year:—

2. Elements of the Methods of Clinical Examination, including physical signs, the use of the stethoscope, ophthalmoscope, &c., and the examination of body fluids (with demonstrations on living subjects, normal and abnormal).

3. An Introduction to Pharmacology.

NOTE.—It is recommended that students should not pass to the period of clinical studies until they have satisfied the examiners in the subjects of the first and second years.

B.—PERIOD OF CLINICAL STUDIES

This period occupies the third, fourth, and fifth years of the medical curriculum proper. These should be calendar years, during which clinical instruction should be continuous.

A minimum period of three years should in every case be given to clinical study in an approved hospital after the completion by the student of the professional examinations held at the close of the second year of the medical curriculum proper.

4. Medicine, including:—

(1) Systematic instruction in the principles and practice of medicine.

(2) A medical clinical clerkship in the hospital wards for a period of six months.

(3) A continuous period of not less than one month in residence in hospital or conveniently nearby, attached to medical wards.

(4) A clinical clerkship for a period of not less than one month in a children's ward or hospital.

(5) Regular attendance in a medical out-patient or equivalent department for a period of three months.

(6) *Regular instruction and demonstrations in applied anatomy and physiology during the period of clinical studies, to be carried out as arranged by the teachers of anatomy and physiology and of the clinical subjects.*

(7) Instruction in methods of treatment, including: (a) dietetics; (b) therapeutics and prescribing; (c) physiotherapy; (d) principles of nursing.

(8) Instruction in the following branches of medicine: (a) disease in infancy and childhood, and child welfare; (b) acute infectious diseases; (c) tuberculosis; (d) *psychology and mental disease and*

deficiency; (e) diseases of the skin; (f) radiology in its application to medicine; (g) theory and practice of vaccination.

NOTE.—Instruction in these branches of medicine should be directed to the attainment of sufficient knowledge to ensure familiarity with common conditions, their recognition and treatment.

5. Surgery, including:—

(1) Systematic instruction in the principles and practice of surgery.

(2) A surgical dressership in the hospital wards for a period of six months.

NOTE.—During his period of surgical dressership a student should spend the greater part of his time at the bedside and in the out-patient department; and he should not be required to attend in the operating theatre unnecessarily.

(3) A continuous period of not less than one month in residence in hospital or conveniently nearby, attached to surgical wards.

(4) Regular attendance in a surgical out-patient or equivalent department for a period of three months.

(5) Practical instruction in surgical methods, including physiotherapy.

(6) Practical instruction in minor operative surgery on the living.

(7) Instruction in the administration of anaesthetics, the candidate being certified to have administered anaesthetics on at least ten occasions.

(8) A course of instruction in operative surgery.

(9) *Regular instruction and demonstrations in applied anatomy and physiology during the period of clinical studies, to be carried out as arranged by the teachers of anatomy and physiology and of the clinical subjects.*

(10) Instruction in the following branches of surgery: (a) disease in infancy and childhood; (b) diseases of the eye and principles of refraction; (c) diseases of the ear, nose and throat; (d) radiology in its application to surgery; (e) venereal diseases; (f) orthopaedics; (g) dental diseases.

NOTE.—Instruction in these branches of surgery should be directed to the attainment of sufficient knowledge to ensure familiarity with common conditions, their recognition and treatment.

6. Midwifery, Infant Hygiene and Diseases of Women, including:—

(1) Systematic instruction in the principles and practice of midwifery and gynaecology, including the applied anatomy and physiology of pregnancy and labour.

(2) Lectures and demonstrations in clinical midwifery, infant hygiene and gynaecology, and attendance on the practice of a maternity hospital or of the maternity ward of a general hospital, and on in-patient and out-patient gynaecological practice, for a period of six months, this period to be subsequent to the medical clinical clerkship (paragraph 4 (2)) and the surgical dressership (paragraph 5 (2)).

During this period the hours of clinical instruction should be so allotted that at least two-thirds are given to midwifery, including antenatal care and the hygiene of infants.

(3) Of this period of clinical instruction not less than two months should be spent as a resident pupil either in a maternity hospital, or in a hostel attached to a maternity hospital or the maternity wards of a general hospital, and these two months should be devoted exclusively to instruction in midwifery and in the hygiene of infants. *The student should during these two months attend at least twenty cases of labour under proper supervision.*

(4) Throughout the six months the student should receive practical instruction in the wards and out-patient department of the maternity hospital in the principles of: (a) antenatal and postnatal care; (b) the management of the puerperium; (c) the care of the new-born infant.

A certificate of having attended twenty cases of labour should be signed by a responsible medical officer on the staff of the hospital, and should state:—

(i) That the student has personally attended each case during the course of labour, making the necessary abdominal and other examinations under the supervision of the certifying officer, who should describe his official position;

(ii) That the first five at least of the twenty cases were delivered by the student in the lying-in hospital or ward;

(iii) That satisfactory written histories of the cases attended, including when possible antenatal and postnatal observations, were presented by the student and initialed by the supervising officer.

7. *Pathology and Bacteriology: Courses of instruction throughout the period of clinical studies in (1) general and special pathology (functional and structural) and morbid anatomy; (2) clinical and chemical pathology; (3) general and clinical bacteriology; and (4) immunology and immunisation.*

Each student should be required to have received practical instruction in the conduct of autopsies, and to have acted as a post-mortem clerk in at least ten cases.

8. A Course in Pharmacology and Materia Medica, including practical pharmacy.

9. Hygiene and Public Health.—Instruction in these subjects should be given during the later stages of the period of clinical studies.

10. Forensic Medicine.—Instruction in this subject and its application to practice should be given during the later stages of the period of clinical studies.

11. Legal and Ethical Obligations of Registered Medical Practitioners.—Instruction should be given during the later stages of the period of clinical studies, by some person having practical knowledge of the subject, on the statutory obligations of registered medical practitioners under the National Health Insurance Acts and other Acts of Parliament, and on the principles of medical ethics. Attention should be called to all notices on these subjects issued by the General Medical Council.

Penal Cases

(Concluded from p. 1366)

A CHARGE OF ADULTERY

The Case of David Edward Stanford Park, registered as of Erinvile, Higher Polsham-road, Paignton, M.B., Ch.B. 1903, U. Edin., who had been summoned to appear before the Council on the following charge:—

That being a registered medical practitioner you abused your position by committing adultery with a Miss Monica Mary Magdalen Blount, a patient at Bay Mount Home, Paignton, Devon, of which you were the manager and medical officer, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated Oct. 30th, 1934, and made absolute on May 7th, 1935, in the case of *Park, Edna Leo v. Park, David Edward Stanford*, in which you were the respondent. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The complainant was Mrs. Edna Leo Park.

Respondent was represented by Mr. O. Hempson, on behalf of the Medical Defence Union, who put in a certificate stating Dr. Park's physical unfitness to attend and expressing fear of the harm that further postponement might do to his health.

Mr. Winterbottom laid the facts before the Council and called Mrs. Park. She testified to her statutory declaration, setting out the facts of the divorce and of the management of the Bay Mount Home for inebriates. As secretary to the company she had dealt with the admission of Miss Blount as a patient. Neither she nor her husband had heard of Miss Blount before. The patient had improved, but had written later that she had relapsed with "nerves." Respondent had gone to see her and thereafter had changed in his manner and ceased to give complainant her usual allowance. Later Miss Blount had returned to the home with jaundice and had been treated professionally by Dr. Park. Suspicion had then arisen, and later—also as secretary to the company—

complainant had opened a letter confirming her suspicions. Respondent had confessed and complainant had forthwith left. Miss Blount had later gone to the home, ostensibly as secretary, and had died at the home in January, 1934, leaving all her property to Dr. Park.

Complainant said she had not been asked to accompany her husband on his holiday; she had never refused to go. It had been agreed long before that one of them should look after the business. She had given up her social life to be with him and look after the home and the patients. She had been too shocked and agitated to think of spite, and had shown the letter to the sister and to Dr. Park's mother and their daughter. No one else had seen it. He had always been delicate and asthmatic. He had gone about the town publicly with Miss Blount.

Cross-examined by Mr. Hempson, she said she had left her husband in August, 1932, and the petition had been served in 1934, very shortly before Miss Blount's death. She did not know that Miss Blount had had to be propped up in bed and her hand guided to sign the receipt for service. She knew Miss Blount was ill, but had asked her solicitor too late not to serve the petition. The delay in commencing the proceedings had been due to attempts to get maintenance. She had not accepted his offers. The order for alimony was considerably less than he had offered, which had been £14 a month as long as Bay Mount was running. The order had been for £1 a month. It had, she admitted, been one fight for money from start to finish. If threat of proceedings before the Council had been held over his head time and time again to enforce maintenance, she did not know of it.

The Legal Assessor pointed out that the only issue before the Council was that of professional relationship.

Continuing, she agreed that her husband's professional work had been confined to the home. It was not true to say that her husband had had no part in the second visit of Miss Blount; or to say that Miss Blount had asked to come as a guest and not as a patient. Miss Blount had not occupied the same room on the second occasion. Witness did not know what she paid then. She remembered seeing her husband make out the bill. Miss Blount had paid 7½ guineas a week the first time. She had been treated for jaundice on the second visit. No other doctor had attended her. She had arrived with a temperature and had gone to bed and been dieted and treated. Witness knew nothing about Miss Blount's arrangements or reasons for coming. She did not suggest adultery during this visit. She had heard that Miss Blount was ill for nearly twelve months, but her husband had been no worse than he had always been.

In reply to the Legal Assessor, witness said that in Miss Blount's letter to her nothing had been said about coming as a patient on the second visit. It had not usually been her duty as secretary to the company to make out the bills: this had been done by her or her husband. It was a limited company and the accounts had been audited. Receipts had been issued by her and her husband and he had fixed the charges without consulting her. The charges had been inclusive of medical attendance.

Mr. Winterbottom read out Miss Blount's will and probate thereof.

Dr. A. R. Pocock said that Miss Blount was his patient for a long time and he had advised her to go to Bay Mount the first time. She had returned practically well. She had later told witness that

Dr. Park had asked her to go again as a guest although she was quite well. He had said "As a patient?" and she had replied "Certainly not." She had had no jaundice to his knowledge, and no other reason for medical treatment.

In reply to Mr. Winterbottom, he said he had seen Miss Blount within a week or two of her departure for Paignton in 1932. He had clearly understood that she would not be paying a fee.

In reply to the Legal Assessor, he said he had often prescribed for her, but not immediately before this visit. She had nearly always had nux vomica and an alkaline mixture.

In reply to members, he said he had written to Dr. Park on the first occasion only but certainly not the second time. He had sent several cases to the home, which took convalescents as well as acute cases.

Mr. Hempson read Dr. Park's statutory declaration and a letter amending it. He admitted dispensing medicine prescribed by her usual medical attendant for Miss Blount during the second visit, when she was convalescent after jaundice. He denied any other medical attendance. The association had then been perfectly proper. Having to pass through London he had arranged to meet her at Paddington, and on the spur of the moment they had spent three days together. The association had then been ended, but Miss Blount had written one letter to him, which had been opened by his wife. The complainant had triumphantly informed the whole neighbourhood. He maintained that he had not abused the professional relationship, which had ceased in May, 1932, when she left Bay Mount and he had never anticipated seeing her again. His wife had threatened to leave him in January, 1932, and had made his life a misery long before he ever met Miss Blount.

Mr. Hempson then addressed the Council, emphasising that Miss Blount had had her own medical attendant all the time and had only been referred to Dr. Park for special treatment for one thing. The case did not present the fundamental factor of privileged admission to the patient's house at any hour or in any circumstances. There had been complete severance of the relationship and no foundation for the subsequent association, which dated from his wife's letter suggesting he should go and see her and take her out. Respondent was broken in health, spirit, and pocket, and his only hope of eking out an existence was to take a few patients well enough to come to him.

Mr. Winterbottom addressed the Council, and after deliberation in camera the President announced that the facts had been found proved and the Registrar had been directed to erase Dr. Park's name from the Register.

ALLEGED CANVASSING

The Case of John Alexander McKinnon, registered as of Claremont, Upper High-street, Thame, Oxon., L., L.M. 1916, R.C.P. Irel.; L., L.M. 1916, R.C.S. Irel., who had been summoned to appear before the Council on the following charge:—

That being a registered medical practitioner you canvassed in or about the month of February, 1935, for the purpose of obtaining patients in respect of your practice as a registered medical practitioner carried on by you at Thame, Oxford: (1) By circulating, or acquiescing in the circulation of, a leaflet headed "To the Residents of Tetworth and District," convening a meeting to be held on Feb. 18th, 1935, at the British Legion Club, Tetworth, to enrol members of a doctor's club, in which it was stated that "The Doctor" (yourself) "with whom arrangements

have been completed, will attend this meeting"; (2) by acquiescing in the calling of and/or agreeing to attend a meeting of the local residents with a view to the formation amongst them of a medical club of which you were to be the sole medical officer; (3) by employing, or sanctioning the employment of, an agent or canvasser who attended the said meeting and invited the persons present and others to become patients of yours by joining the doctor's club. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

The complainants were the Medical Defence Union, for whom Mr. O. Hempson appeared. Dr. McKinnon was represented by Mr. T. Carthew, counsel, instructed by Messrs. Le Brasseur and Oakley, solicitors to the London and Counties Medical Protection Society. Mr. Hempson said that respondent had set up in Thame without purchasing any practice; such a man had to be particularly careful what he did, as it was to be presumed that all residents already had their own doctor. The formation of a club was unobjectionable, but it was objectionable in the extreme to canvass a club of which one doctor only was medical officer. Mr. Hempson read a letter from respondent's solicitors which he characterised as an admission of the charges.

Mr. J. C. Everett, solicitor, testified to his statutory declaration in which he stated that he had seen a handbill, and in consequence had attended a meeting called by Mr. Crump, secretary to the local branch of the British Legion. Respondent had opened the door of the hall. Mr. Crump had spoken to him and left the hall, shortly returning to address the meeting. He said "they" had spoken to the doctor (respondent) about it and fixed subscriptions. The doctor had had nothing to do with calling the meeting, but had intended to be present; he had, however, been called to an urgent case and hoped to return.

In answer to Mr. Carthew, witness agreed that he had gone there on the instructions of a local doctor to see what went on. The substance of his declaration had been written down by him immediately after the meeting. He did not remember if Mr. Crump had said the meeting was to discuss the possibility of forming a club, and that subscriptions to the club would not affect payments to the Radcliffe Infirmary.

Mr. T. W. Ludgate, clerk to Mr. Everett, testified to his statutory declaration and said that respondent had attended the meeting in question. Cross-examined by Mr. Carthew, he thought Mr. Crump had said "with a view to forming" the club, and did not think he had said people were not being pressed to leave their own doctors.

Mr. W. F. Small, gardener in the employ of a local doctor, had attended the meeting on his master's instructions and in consequence of a handbill. He gave a similar account of what had been said. Cross-examined, he said he had written the declaration in the doctor's surgery, with his help. He could not explain a difference between his own rough notes made at the time and his statutory declaration; the former said "proposed to start" a club, and the latter said "call to enrol members." He supposed that his employer had suggested the words.

Mr. Hempson read a statutory declaration from the chairman of the local branch of the British Legion disclaiming the meeting and saying the Legion knew nothing of the club.

Dr. McKinnon, examined by Mr. Carthew, said he practised at Thame and had just taken a partner. He was a member of the British Legion. Mr. Crump was secretary of the Tetsworth branch and a patient of his, and had approached him, asking if he could

do something for the poorer members of the Legion. There had been a club in the district before. He had not agreed to be the doctor, and it was left to Mr. Crump to let him know details of what was wanted. He had never run a club. He had agreed to go to the meeting to discuss possibilities. He had first seen the leaflet when solicitors sent it him many months later; he had had no knowledge what steps Crump was taking and had no idea there was a handbill. On the day of the meeting he had gone to the Legion Hall about 3.30 p.m. and Crump had come out to him and had a conversation. Respondent had then returned to Thame. Crump had had no authority to say he had agreed to accept club members as his patients; he had never promised to do that. Arrangements had never even been discussed. He had never seen the letter sent by his solicitors to the Registrar.

Mr. Hempson cross-examined respondent, who said he disagreed with the letter of his solicitors. He had said he was prepared to act as medical adviser to the club if in the event it proved agreeable to him. When he had called Crump out he had asked if it was a public meeting, and on hearing that it was had said he could have nothing to do with it as the procedure was quite wrong, and he had made it perfectly clear that he would have no more to do with it. It was not true that he had been prepared to go on until he heard of the circulars.

Mr. Carthew re-examined, and then called Mr. Crump, secretary to the Tetsworth branch of the British Legion. He testified that up to January, 1934, there had been a Legion club but then its doctor had notified members that he was not going on. Witness had been very anxious to start another club because so many poor people could not afford a doctor. He had spoken about it to Dr. McKinnon during January, and the doctor had replied that he was willing, but nothing definite had been settled. He himself had composed and ordered and paid for the handbills. The doctor had had nothing whatever to do with them, and did not know they were being ordered. He had told Dr. McKinnon of the time and place of the meeting. He had put "with whom arrangements had been completed" on the circular because he thought everything would be all right. He took full responsibility for the handbill, which he sent out to all members of the Legion and the club run by it. Fifty had been printed, but a few had been left over. The work was done through the benevolent committee which was nothing to do with the chairman of the local branch. He had explained at the meeting that the club subscription would not interfere with existing hospital payment schemes and had tried to explain that the club was only for those who were too poor to afford a doctor.

Cross-examined by Mr. Hempson, witness agreed he had been disappointed that Dr. McKinnon could not attend the meeting. He had not discussed fees with the doctor.

Mr. Carthew, addressing the Council, argued that Mr. Crump had been solely responsible for the circular. Respondent had agreed to attend a meeting but had thought it was a committee meeting of the Legion. When he arrived and saw the nature of the meeting he had made an excuse and gone away.

Mr. Hempson emphasised a direct conflict of evidence between respondent and Mr. Crump. He did not accept Dr. McKinnon "as the fool he appeared in the box" or as an honest witness. The meeting, in his opinion, had been called with the knowledge and approval of respondent.

After deliberation in camera the President announced that the facts in the preamble and in para. (2) and (3) of the charge had been found proved, but not the fact in para. (1). The methods were contrary to the public interest and profession of medicine, but judgment had been postponed until November, 1936, with the usual provisos.

Restorations after Non-Penal Removal

At the meeting of the executive committee preceding the Council meeting the names of the following persons had, on fulfilment in each case of the prescribed conditions, been restored to the Register, from which they had been erased under Section 14 of the Medical Act, 1858:—

Bushe, Joseph B. (S).	McCullough, William W. (I).
Campbell, James McN. (S).	McElroy, William (S).
Clarke, John J.	Melrose, Thomas R. G. (S).
Cresswell, Norman (I).	Pasco, Bernard C. W.
Dyet, (Mrs.) Mary E. (S).	Phillips, Lionel L.
Evison, Frank A.	Rankin, Reginald J.
Jones, William E.	Sleigh, George B. (S).
Kenealy, Arabella M.	Smith, Alistair H. (S).
Lloyd, John T.	Thistlethwaite, Eleanor C. (S).

The letter (S) or (I) after a name indicates that the name was sent for restoration by the registrar of the branch council for Scotland or of the branch council for Ireland.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

PREGNANCY WASTAGE

HITHERTO only rough estimates of the number of abortions in the United States have been available and even these have lacked any attempt to distinguish between legal and illegal abortions. A basis for more exact study has been found by Dr. Regine K. Stix of the Milbank Memorial Fund in the records of birth control clinics. In this confidential haven of the overly pregnant accurate histories have been recorded. Of the 991 women whose records were studied two-thirds were Jewish, one-sixth Catholic, and the remainder Protestant. Half of the women were foreign-born. The total number of pregnancies was 3106, of which only 35 were due to premarital intercourse. Seventy per cent. of the pregnancies terminated in live births, 20 per cent. in illegal abortions, and the remaining 10 per cent. in spontaneous abortions, therapeutic abortions, ectopic pregnancies, or stillbirths. A smaller proportion of Catholic pregnancies were aborted than of Jewish pregnancies; not that the Catholic women resorted less frequently to abortion, but they became pregnant more frequently than the Jews. Six per cent. of the Jews and 11 per cent. of the Catholics had experienced three or more illegal abortions. Dr. Stix is careful to point out that since all the histories were compiled in a birth control clinic the women may not be truly representative of their religious groups.

The proportion of pregnancies terminating in live births declined rapidly with length of marriage. Less than one-fifth of first pregnancies were accidental, but of the conceptions occurring in the period 15-29 years after marriage nearly three-fourths happened in spite of contraceptive efforts to prevent them. Nearly 40 per cent. of such "accidental" pregnancies were terminated by illegal abortion.

By comparing corresponding periods of married life at different dates it is shown that during the last

25 years there has been a big increase in the proportion of pregnancies terminated by illegal abortion. The younger generation, it seems, not infrequently resorts to abortion for economic reasons early in marriage and later indulges in "planned pregnancies" when the family's finances permit. Nearly 75 per cent. of illegal abortions were performed by "doctors," 20 per cent. by midwives, and the remainder by the woman herself. The price charged for inducing abortion varied from \$2 to \$200, the average being \$60.

NEW RICH SOURCE OF VITAMIN B

Research at the experiment station of the New Mexico College of Agriculture has discovered an uncommonly rich source of vitamin B in the pinto bean. By the rat-growth method these beans are found to have 298 Sherman units of vitamin B (English B₁) per ounce of food material. This is more than is found in rice polishings, only slightly less than in wheat germ, and more than half the quantity found in dried brewers' yeast. The pinto bean belongs to the botanical species *Phaseolus vulgaris* and was probably introduced into the south-western States by the early Spanish missionaries. It has been a staple diet of the natives of these States since it was popularised by use in the army during the Spanish-American war. Until comparatively recently it was known as the rosillo bean. The name pinto means "spotted" and is no doubt a tribute to the bean's macular complexion. The production of this bean in New Mexico increased from 9700 bags (of 100 lb. each) in 1879 to 974,900 bags in 1929. Properly cooked these beans make a very succulent dish.

STUDY OF HEART DISEASE

Death from "heart disease" is a very unsatisfactory classification, covering as it does many diverse pathological states which happen to affect the same organ. A study by the U.S. Public Health Service of 450 fatal cases of heart disease occurring in Washington hospitals during the year 1932¹ reveals the following percentage classification:—

	Per cent.		Per cent.
Arterio-sclerotic hypertensive diseases	61.4	Congenital malformations	2.0
Rheumatic	13.3	Thyrototoxic	1.3
Syphilitic	12.0	Other conditions	0.6
Bacterial endocarditis and pericarditis	4.7	Undetermined	4.7

Special emphasis is laid upon the importance of arterial hypertension in causing death in middle life. Hypertension is more fatal in the negro than in the white race, more fatal especially among coloured females. This prevalence of hypertension among negroes together with the greater syphilis rate in this race results in cardiac death at a lower average age than in the whites. Rheumatic heart disease on the other hand is more common in the white race, especially among females.

INTERNATIONAL CONFERENCE ON FEVER THERAPY. The first international meeting on fever therapy will be held in New York City next September, when therapeutic, physiological, and pathological phases of fever will be discussed. Baron Henri de Rothschild is the chairman and the secretary is Dr. William Bierman, 471, Park-avenue, New York City, U.S.A., from whom further information may be obtained.

CORRESPONDENCE

THE MIDWIFERY SERVICE IN LONDON

To the Editor of THE LANCET

SIR,—In a recent letter in your columns (Nov. 16th, p. 1145) Dame Janet Campbell called attention to a number of important questions which need solution before any plan for a salaried service of midwives can be launched with good prospects of success. Dame Janet assumed the establishment of the proposed service under local authorities; but in the metropolitan area of London the existence of two public health authorities involves a difficulty as great as any she enumerated. Here one of the first decisions must be whether the London county council or the local borough councils shall inaugurate and control the proposed service.

Since no small proportion of hospital midwifery has passed already within the administration of the L.C.C., it would seem to be an obvious and logical step to extend the scope and powers of this body to include the new domiciliary service; for a large number of examples have already made clear how great are the advantages of a single unit controlling midwifery in a hospital and the homes surrounding it. Since, however, the child welfare service is, and seems likely to remain, the responsibility of local authorities, such arrangement would separate officially and in practice would virtually isolate midwifery and infant care from each other: two branches of work whose individual success must depend on the closeness of their coöperation.

If, on the other hand, it be decided that a salaried service of midwives shall be the responsibility of the local authorities, its value must be largely diminished by hospital and domiciliary midwifery being under separate control. To perpetuate two midwifery services operating in the same area, one serving women to be confined at home, the other those who are going into hospital, both requiring the organisation of antenatal care and experts to pronounce on cases of doubtful safety, one service in emergencies having to come to the assistance of the other—this is surely no advance towards efficiency, simplicity, or economy. It is exactly the opposite.

Further, as the postnatal care of women develops (beyond, that is, the present rather formal conception of a gynaecological examination at one or two fixed dates after delivery), the importance of the present widespread incidence of maternal ill-health will come to be increasingly realised, with all its repercussions on the health of infants and the family. It may thus be predicted with certainty that post-natal supervision must comprise not merely a "pelvic overhaul" but the attempt to control all those factors which concern a woman's general health and influence her ability to succour her child. Further, it must continue to safeguard her so that after an appropriate interval she can repeat the process. What is needed is a service to which she can turn throughout the period of her reproductive life with confidence that her particular needs are known and understood: a service comparable in fact to what she would receive from her general practitioner if she could afford it. Hitherto in the working of the Maternity and Child Welfare Act not much appreciation of this has been shown.

Advance will be rendered as difficult as possible if women confined in hospital are retained indefinitely as its out-patients, while for those confined at home a separate service has to be organised; for unless all domiciliary cases are to be referred to

hospital two postnatal—just as two antenatal—services will be needed. Existing confusion will be further increased as the different authorities attempt to decide which shall provide care for the infant while the mother remains under hospital supervision. Solomon himself would be puzzled. There is no limit to the prospect of overlap and waste which must result, nor with the best will in the world can it be supposed that friction and competition can be avoided. The sufferers in such event, as always, will be the very persons it is desired to help—the mothers and their infants.

This apparently simple and eminently sensible proposal to improve the conditions of midwives and the quality of their work is long overdue. It might well mark a nodal point in the histories of both midwifery and public health. Its establishment in London is intertwined with a number of absurd anomalies which frustrate effective advance in public health in many directions. I submit, Sir, that an invaluable opportunity here arises to remove them, and that the Minister of Health, the London county council, and local borough councils should at this juncture combine, and, subordinating departmental claims, bring into being a single service uniting all those activities which can be directed with profit towards increasing the safety of mothers and children. The difficulties are considerable, but they could be overcome. Public opinion is aroused and would surely give support to such an endeavour.

I am, Sir, yours faithfully,

HAROLD WALLER.

Royal College of St. Katharine, Poplar, Dec. 9th.

CYSTICERCOSIS AND EPILEPSY

To the Editor of THE LANCET

SIR,—In reading reports on possible cases of cysticercosis one cannot but be impressed by the widespread miscomprehensions which exist regarding this disease. The biological object of cysticerci while in the tissues of the intermediate host is to remain quiescent; they may be likened to thieves who have entered some premises where they stay hidden so long as concealment is helpful to their purpose. In the same way, cysticerci normally give little or no outward sign of their presence (unless crowded out by their own numbers) while they are alive, but after their death they cause symptoms by post-mortem swelling and by the liberation of toxic products of degeneration. Consequently a period of several years commonly elapses between the invasion of the body and the onset of clinical symptoms, of which the most frequent is epilepsy.

During the life of the host, diagnosis for practical purposes is at present dependent on only two signs, neither of which unfortunately is a necessary part in the development and degeneration of the parasite—namely, the appearance of palpable cysts in the tissues, and their calcification post mortem. As regards the first mentioned there may be no cysticerci outside the brain, and even if present in muscle, &c., as well they may be too deep for detection and excision when post-mortem swelling occurs; or so few in number as to escape notice; or the host may come under examination only at a time when he is free from palpable cysts although some may have been present months or years before, or may appear months or years afterwards, as determined by the longevity of individual parasites. Calcification is found only as a form of post-mortem degeneration,

and as a rule a period of about three years elapses between the death of a cysticercus and the deposition of calcium sufficient for recognition in a skiagram. Some parasites may die off quickly, while others in the same host may remain alive for many years and, speaking generally, a positive skiagram can hardly be expected if the patient's nervous symptoms are of less than four or five years' duration. On the other hand, if the silent stage of the disease has extended (say) to over five years, calcified parasites might be detected somewhere in the body at the time of the onset of the nervous symptoms. It cannot be emphasised too strongly that, as a rule, the cysticerci in the brain do not calcify, and so cannot be seen in a skiagram; radiological examination, therefore, should never be limited to the skull.

For every case of cysticercosis immediately diagnosable, there is a large number which will defy diagnosis for years, or which can be recognised only by autopsy: and even after death the presence of a few cerebral cysticerci—only one or two in all—might "unless the pathologist has cysticercosis in mind, knows what to look for, and leaves no scrap of brain substance more than four millimetres square, unsearched."¹

I am, Sir, yours faithfully,

W. P. MACARTHUR.

Royal Army Medical College, London, S.W., Dec. 12th.

ARTERIAL EMBOLISM

To the Editor of THE LANCET

SIR,—I was much interested in reading in your issue of Nov. 30th (p. 1231) of Mr. Girdlestone's experience of a femoral embolus and its spontaneous cure at the time of operative exposure. May I refer to a somewhat similar experience of my own in 1911, the details of which were published later (Clin. Jour., Dec. 10th, 1913, p. 573) together with details of another case too ill to operate on.

A man, aged 60, was operated on for carcinoma of the larynx by the late Mr. F. A. Rose and the entire larynx successfully removed. A fortnight later the patient was suddenly seized with pain and tingling in the left foot which was followed by ascending pallor, loss of sensation and power in the left leg. Six hours later when I examined him no pulse was felt below the bifurcation of the common femoral, and the leg was cold, pallid, and insensitive from the knee downwards. I at once exposed the common femoral artery. Pulsation was found to cease at the bifurcation. After opening the sheath I raised the artery in order to apply a Crile's clamp above and below, when pulsation suddenly returned in the superficial femoral. As I could not satisfy myself of pulsation low down in Hunter's canal, I exposed the artery at this point, and found that the vessel pulsed as far as the middle of the popliteal space. On the following day some warmth returned to the foot, but the tibial arteries were pulseless. Gangrene of the foot eventually became established, and a week later I amputated the leg through the condyles of the femur. The artery was completely blocked at the bifurcation of the popliteal and thrombosis extended down both tibial arteries. The patient made a good recovery.

In the light of subsequent events I should have exposed the artery in the popliteal space, but I thought then that I might make matters worse if the clot again shifted into the tibials and that the collateral circulation round the knee might be adequate. As Mr. Girdlestone states, the happy accident in his case might be an aim on other occasions; Mr. Geoffrey Jefferson, he reminds us, suggested last year at the B.M.A. meeting at Bournemouth a deliberate attempt to massage the blood-clot

into a subsidiary artery. In my 1913 paper I referred to two successful cases of *pétrissage* for femoral embolism without exposure of the arteries by Paul Claisse (Bull. Soc. méd. hôp. de Paris, June 10th, 1910, p. 766) and Pierre Merklen (ibid., Nov. 6th, 1903, p. 1180).

Although many successful cases of embolectomy have been recorded there have been a great many failures, including one of my own (Brit. Med. Jour., 1926, i., 1032), owing to subsequent thrombosis towards which the opening of the artery must be a contributory factor, and I am not sure that *pétrissage* after exposure of the artery has received sufficient prominence. It may not be out of place to quote here what I said in 1913:

It may well be asked which method offers a better chance of success as regards gangrene—exposure of the artery and an attempt to break up the clot by massage, or incision into the artery and an attempt to re-establish the channel by removal of clot. There are two important factors to consider—viz., (1) condition of the lining of the vessels; (2) length of time that the vessel has been occluded.

(1) If the patient is old and suffering from arteriosclerosis, subsequent thrombosis is likely to occur, even if an embolus is successfully removed, and consequently *pétrissage* should offer more chance of success, even though resulting in the blocking of vessels lower down. In these cases immediate massage of the affected part should first be tried, and if unsuccessful the artery should be exposed and an attempt made to dislodge the embolus by *pétrissage*. In the case of a patient under middle age, with healthy vessels, arteriotomy conducted on careful lines should, I think, be the method of choice. A proximal clot rapidly forms as far up as the nearest branch. This fact must not be forgotten in operative procedures.

(2) The lodgment of an embolus in an artery is rapidly followed by thrombosis, the extent of which will depend on the condition of the heart and arteries and on the size of the vessel. Consequently, the earlier the attempt at embolectomy, the greater the likelihood of success. At the same time massage is less likely to succeed once thrombosis has become established.

I am, Sir, yours faithfully,

London, W., Dec. 12th.

C. GORDON-WATSON.

TREATMENT OF HÆMATEMESIS

To the Editor of THE LANCET

SIR,—I also have read Prof. Meulengracht's article with great interest. It seems to me that we should depart from the present line of treatment. Figures collected over a period of time and in various clinics would suggest that there was room for improvement, and I welcome Prof. Meulengracht's method as one which at least relieves the patient of a form of treatment which is so definitely lowering, and from the patient's point of view must be in the nature of a mild degree of torture. The stomach in the ordinary way is constantly being supplied with saliva and is also supplied with a defence mechanism which prevents digestion of its mucous membrane. When an ulcer bleeds we take the patient, prevent as far as possible the flow of saliva, and by keeping his stomach empty allow his acid gastric juice to have free play on the raw ulcer area, which is defenceless; the evidence would go to show that at the same time such an empty stomach is in more active movement than a partially filled, or full, one. We have then at the outset all the factors that are likely to promote further hæmorrhage. Seven years ago I pointed out (Brit. Jour. Surg., 1928, xvi., 203) that saliva had a very potent action in decreasing the clotting time, whereas the acid gastric juice, especially in the case of an ulcer, delayed the clotting of blood very considerably.

¹ Trans. Roy. Soc. Trop. Med. Hyg., 1933-34, xxvii., 355.

It would appear to me that in Prof. Moulengracht's treatment he is providing—

- (1) That the patient's general health should be maintained.
- (2) That the movements of the stomach are reduced by its being kept partially filled.
- (3) That the acid juice is neutralised by food and alkalis.
- (4) That a free flow of saliva is produced to further assist clotting.
- (5) That the patient is relieved from the stress of thirst and an uncomfortable posture, and, as the article points out, is more easily nursed.

I hope that physicians in this country will give his method a trial, and I shall look forward to seeing in your columns at some later date further figures on this subject.—I am, Sir, yours faithfully,

Harley-street, W., Dec. 11th.

JOHN B. HUNTER.

PAIN AND EUTHANASIA

To the Editor of THE LANCET

SIR,—I have read with interest your report of the inaugural meeting of the Voluntary Euthanasia Legalisation Society, and I have noticed how the argument returns again and again to the inadequacy of drugs, particularly morphin, to relieve intolerable pain. I wonder if the members of this society are aware that no patient need suffer intolerable pain from any local disease situated below the segmental level at which a bilateral chordotomy can be done—that is, the fifth cervical segment of the spinal cord. It is true that in a particular case the operation might prove fatal; but that surely would meet with the approval of the Society. As a matter of fact, the operation is not particularly difficult or dangerous, and I have never known of a death directly due to it. This is not put forward as an argument against the aims and objects of the Voluntary Euthanasia Legalisation Society; but it does seem to me to limit the field of their concern very considerably. The real purpose of this letter is to suggest that those who are especially concerned with the treatment of such conditions as, for example, inoperable carcinoma of the pelvic organs, might give more than a passing thought to the possibility of the surgical relief of pain.—I am, Sir, yours faithfully.

London, W., Dec. 14th. A. S. BLUNDELL BANKART.

To the Editor of THE LANCET

SIR,—I imagine that I am not the only doctor who was surprised to see three pages of THE LANCET occupied by an account of the inaugural meeting of the Voluntary Euthanasia Legalisation Society. Why should pages of a medical journal be filled with a description of a meeting to advocate measures which have nothing at all to do with medicine, except that a number of medical persons are members of the society? And, when one reads the report, one finds no reason for its publication in THE LANCET. The gist of the résumé is that some deaths are painful; and that some clergymen see nothing incompatible between Christianity and euthanasia. That did not need three pages.

One may presume, Sir, that you know the tastes of your readers, and that the report was inserted because you thought that it was proper to do so. All I desire to do is to make clear one misunderstanding that seems to lurk in Lord Moynihan's mind. He is reported to have said, "There were denominations within the Christian Church whose members had no right to such relief—that for which sanction was desired; these persons were asked to stand aside." These persons do not believe

that they alone have no right to disobey the laws of God; they believe that it is a part of their duty to inculcate these laws into the minds of others; and, therefore, they will not stand aside. Lord Moynihan can rest assured that "these persons" will do everything in their power to rouse public opinion against a procedure which they regard as mortally sinful. These same persons will not be misled by Mr. Norwood, who is reported to have said that "the principal concern of religion was more with the entrance and conduct of life than with its exit." They will remember the divine assurance that the mode of exit from life of the penitent thief had a very definite effect on his comfort elsewhere.

The sole purpose of this letter is to point out that there are various organisations, some Roman Catholic, some undenominational—some medical and some lay—which are prepared for the battle.

I am, Sir, yours faithfully,

Park-square West, N.W., Dec. 13th.

A. PINNEY.

A TEST FOR CANCER

To the Editor of THE LANCET

SIR,—The letter published in your columns on Dec. 14th above the signature of Dr. G. Burford and others is either of extreme importance or very mischievous. But whether it relates to a genuine test for cancer or to one of no value it is almost certainly going to attract a number of guineas to the address given in Park-crescent. I will be obliged if you will give equal publicity to the following challenge—I will send to that address twenty specimens of urine collected under the conditions mentioned and clearly labelled A to T, the results of the tests, together with the correct diagnosis in each case, to be published subsequently and prominently in your columns. But I do not propose to send any money in payment for this test because, if the claims made are substantiated, a much greater reward is inevitable.

I am, Sir, yours faithfully,

London, W., Dec. 16th.

T. IZOD BENNETT.

GASTROCOLIC FISTULA

To the Editor of THE LANCET

SIR,—I should like to add my opinion to that of Dr. Hurst (in your issue of Nov. 16th) that the result of dealing with a gastrocolic fistula by simple disconnexion is an operation which has not necessarily a high mortality. I have not met with a single case during 1935, but I performed the operation three times during 1934 and recovery was uneventful in each case. Although I agree with Dr. Hurst that thorough lavage is of great advantage, I do not agree that the operation calls for the exceptional skill he suggests, and I am putting these cases on record to encourage surgeons of ordinary ability when they feel called upon to deal with such cases in this way.

Precautions making for safety in this operation are:—

- (1) To avoid soiling the site during operation, and to drain it afterwards.
- (2) To close the colon and jejunum without narrowing—in one case I left some narrowing of the colon at the site of suture and this persisted some 9 months later.
- (3) To support sutures in a somewhat unhealthy gut with an omental graft.
- (4) To prevent by caecostomy postoperative distension of the proximal colon, which would lead to strain on the suture line.

I am, Sir, yours faithfully,

Harley-street, W., Dec. 11th.

TURNER WARWICK.

EPIDEMIOLOGY OF PUERPERAL SEPSIS

A NEW INVESTIGATION

It is estimated that more than a third of the mothers who die after childbirth every year in this country die as a result of sepsis. Generally speaking, over 70 per cent. of the fatal cases of puerperal sepsis are due to the hæmolytic streptococcus.

THE SOURCE OF THE INFECTING ORGANISM

The source of the infecting organism has been the subject of keen research, a crucial question being whether it is usually present in the genital tract before labour, or whether it comes to it from the outside.

The *genital flora* has been extensively studied before, during, and soon after labour, with the result that the hæmolytic streptococcus is found to occur in about 3 per cent. of the patients studied. It appears, however, that a minority only of these "carriers" become infected in the puerperium, the infection when it does occur being generally mild and quite unlike that usually associated with fatal streptococcal infection. The explanation lies in the fact that the hæmolytic streptococci do not form a homogeneous group, and that those found in the genital canal of pregnant and parturient women are not pathogenic to the human subject. The work of Lancefield,¹ Hare and L. Colebrook,² and Lancefield and Hare³ shows that the biochemical and serological characters of hæmolytic streptococci are closely correlated with the pathogenic capacities. For example, the streptococci responsible for bovine mastitis belong to a well-defined group rarely found in severe human infections; while the majority of strains from acute human disease belong to another group distinct from the bovine strains. The genital streptococci found as saprophytes before and during labour fall into serological groups different from that containing the streptococci found associated with acute disease in the human being. Further work by Hare and Colebrook⁴ has demonstrated that not only the streptococci present in the flora of the genital tract but those found present on the normal skin of the hand and perineum, and in the bowel, show no evidence of marked pathogenicity for man.

There remain for consideration streptococci from *extragenital septic conditions* and from the *respiratory tract*, both of the patient and of those in contact with her. Respiratory streptococci have been incriminated with varying degrees of vehemence as a source of puerperal infection, while other workers boldly deny their ætiological significance.

The available evidence on the whole points to the respiratory streptococci as the causal organisms of puerperal sepsis, and the recent observations of Smith⁵ support this view. He found strains of streptococci identical with the infecting strain in the respiratory tract of the patient or a contact in 39 of the 49 cases of puerperal sepsis studied.

DIFFICULTIES AND POSSIBLE FALLACIES

The connexion between a particular hæmolytic streptococcus carried by an apparently healthy person and a streptococcal puerperal infection is difficult to demonstrate. It is necessary to make a careful epidemiological study of the infecting strains in a large number of women with puerperal infection, and of the strains found in streptococcal carriers concerned more or less immediately with the woman

during and after the time of her confinement, before any conclusions can be drawn. Dr. Dora Colebrook, working at the Bernhard Baron Memorial Research Laboratories attached to the isolation block of Queen Charlotte's Hospital, has now carried out a study, on lines similar to that published by Smith, which has just been published as No. 205 of the Special Report Series of the Medical Research Council.⁶

Dr. Colebrook discusses fully the fallacies inherent in this method of approach to the problem. Briefly, no source of infection can be considered a possible one unless the streptococcus found in it is identical with that in the infected genital tract. In addition, adequate opportunity for the passage of the streptococcus must be demonstrated. The two main problems are therefore the establishment of identity between strains of streptococci, and the adequate exploration of the human environment of the patient.

CRITERIA AND METHODS ADOPTED

The criterion of identity adopted in this study was a serological one. Strains were classified into Griffiths'⁷ types by direct agglutination with mono-specific sera. This revealed a series of provisional identities which were confirmed by further test. A complete serological identity between two strains can be proved only if each absorbs all the agglutinins from the antiserum prepared against the other. The method must be rigidly quantitative to be of any value. Accordingly the minimal absorbing dose (M.A.D.) of each strain for its homologous serum was determined, using the latter at a definite multiple of its agglutination-end-point concentration, and the test strain was considered identical only if 3 M.A.D. would remove 98.5 per cent. of the agglutinins from the serum. Control absorptions were made with strains known to be heterologous.

The patients used for this investigation were suffering from a pyrexia, more or less severe, whose onset was within three weeks of confinement. Swabs were taken from the genital tract and from the anterior nares, tonsils, and sometimes gums. The contacts included nurses, doctors, the "handy-women" at the confinement, and the husband and children of the patient. Attention was paid to points of special ætiological importance, such as a person with a recent history of tonsillitis, scarlet fever, or chronic nasal discharge. Dr. Colebrook points out that the ease with which hæmolytic streptococci can be passed from person to person makes it difficult to be certain that many of the contacts, of necessity swabbed some time after the infection had developed, were not carriers as a result of dissemination of the puerperal strain. (Contact swabbing was carried out as soon as possible after the discovery of streptococcal infection.) In addition, there can be no conclusive evidence that identical strains in a contact and the genital tract of the patient had not been independently acquired. When the type of streptococcus is relatively rare, the likelihood is remote, but with a prevalent strain the possibility must be considered.

The finding of an identical streptococcus in contact and patient, therefore, indicates only a *possible* source of infection, though in certain cases circumstances may point to its being a very probable one. The material gathered was considered complete if all persons that could be ascertained as having taken part in the conduct of the labour had been examined, or if, in spite of one or more attendant-contact swabs being missed, identical streptococci were found in another of the contacts. Incomplete

material included all groups in which a possible swab was missed, and no identity between genital and contact strains was established.

RESULTS OF THE PRESENT INVESTIGATION

Sixty-seven patient-contact groups were investigated, and an extragenital strain serologically identical with the infecting strain was found in 48 of them. In 14 the possible source was present in the respiratory tract of both patient and contact. In 11 an identical strain was found only in the patient herself (in 5 of these groups the material was incomplete). In 23, identical strains were found in contacts only. In 4 groups technical difficulties prevented the establishment of identity, though streptococci were found in contacts. In the 15 remaining groups, no possible source of infection was found.

A possible source was found in the patient's own respiratory tract 24 times.

The social relationship of the patient with the carrier is of interest. A strain identical with the infecting strain was isolated from—

(1) The doctor	in 5	} patient-contact groups
(2) The midwife	15	
(3) The handwoman	3	
(4) The husband of the patient	3	
(5) The mother or father of the patient	2	
(6) A child of the patient	8	

and in 3 groups the infecting strain was found in the ear of the patient's child, the septic foot of the patient's child, and the septic foot of the patient.

To summarise, an extragenital strain was found for 48 patients out of 67. Dr. Colebrook points out that—

"owing to failure, in the early stages of the work, to realise the importance of swabbing the nose as well as the throat of patient and contacts, and the members of the household of the patient as well as her attendant-contacts, and owing to the difficulties experienced in securing the full complement of swabs, and to the use, in certain cases, of an ineffective swabbing technique, the figure quoted above is fallaciously low. Thus, in the 31 patient-contact groups in which the patients, and, so far as could be ascertained, all their attendant-contacts were swabbed, a possible source for the infection of 27 (87 per cent.) patients was found, whereas in the 32 patient-contact groups in which swabs were known to be missing, the percentage was only 65; in the case of 4 only of the 15 patients for whose infection no source was found was the full number of swabs received from patient and attendant-contacts, and in the case of one only of these 15 patients were swabs taken from the children of the household."

IMPORTANCE OF RESPIRATORY CARRIERS

These figures indicate that the respiratory source of infection must be taken very seriously. If Dr. Colebrook's figures may be taken as a representative sample of cases of puerperal sepsis, a large proportion of these deaths from this cause are attributable to infection by a carrier of pathogenic streptococci. The causal linkage may not be established with mathematical certainty, but it is established as firmly here as in many other diseases where a superstructure of stringent precautionary measures has been based on the laboratory evidence. And the fact that the majority of strains isolated from patient and contact fall into a limited number of Griffiths' types, types commonly met with in other diseases (including respiratory) caused by hæmolytic streptococci, affords indirect support to her finding. The result of rigid precautionary measures in the conduct of labour in certain hospitals indicates that technical improvements can lower the incidence of sepsis. Adequate

masking of personnel, intelligently applied antiseptic technique, and the exclusion of carriers from the attendants are among the measures indicated for trial. In addition, steps should be taken to ensure the continued exclusion of carriers from contact with women in labour and during the puerperium by collaboration between the bacteriologist and the clinician.

The familial carrier is a problem that this report has brought to light, and although the number of families investigated by Dr. Colebrook is insufficient to give any indication of the magnitude of the risk of infection to which a pregnant woman is exposed to in her family life, the suggestion that here is an indication for the education and assistance of the expectant mother on matters of hygiene which may have important results is not the least valuable of the conclusions Dr. Colebrook has to offer.

PHYSIOLOGICAL BASES OF NUTRITION

REPORT OF A TECHNICAL COMMISSION OF THE LEAGUE OF NATIONS

THE report on the physiological bases of nutrition drawn up by the Technical Commission of the Health Committee of the League of Nations which met¹ in London from Nov. 25th–29th was published at Geneva on Dec. 6th. The Commission is in agreement with the conclusions of the Burnet and Aykroyd report² that deficiencies in important nutrients are a common feature of modern diets and that these deficiencies usually occur in the protective foods (foods rich in minerals and vitamins) rather than in the energy-giving foods (proteins, fats, and carbohydrates). The Commission has set out its findings in two parts: Part I. dealing with the requirements of energy-giving foods; Part II. with mineral and vitamin requirements.

PART I

Energy, Protein, and Fat Requirements

CALORIE REQUIREMENTS

An adult, male or female, living an ordinary everyday life in a temperate climate and not engaged in manual work is taken as the basis on which the needs of other age-groups are reckoned. An allowance of 2400 calories net per day is considered adequate to meet the requirements of such an individual.

The following supplements for muscular activity should be added to the basic requirements:

Light work :	up to	50	calories per hour of work.
Moderate work :	"	50–100	" "
Hard work :	"	100–200	" "
Very hard work :	"	200	calories and upwards per hour of work.

The energy requirements for other ages and for

¹ THE LANCET, Nov. 30th, p. 1270, and Dec. 7th, p. 1305.
² *Ibid.*, August 10th, p. 311.

mothers can be obtained from the following table of coefficients:

Age (years).	Coefficient.	Calories.
1-2	0.3	720
2-3	0.4	960
3-5	0.5	1200
5-7	0.6	1440
7-9	0.7	1680
9-11	0.8	1920
11-12	0.9	2160
12 and upwards (male and female)	1.0	2400

Women			
Pregnant	1.0	2400	
Nursing	1.25	3000	

The requirements for babies under 1 year are difficult to specify except in terms of body-weight, but the following allowances are considered adequate:

Age (months).	Calories per kilogramme of body-weight.
0-3	100
3-6	90
6-12	80-90

The muscular activities characteristic of every healthy child and adolescent necessitate additions to the basic requirements. It is suggested that the activities of children of both sexes from 7-11 years be considered as equivalent to light work, of boys from 11-15 years as moderate work, and of girls from 11-15 upwards as light work.

Allowance must also be made for women engaged in household duties, whether pregnant or not; these have to be reckoned as equivalent to light work for eight hours daily.

PROTEIN REQUIREMENTS

In practice the protein intake for all adults should not fall below 1 gramme of protein per kilogramme of body-weight. The protein should be derived from a variety of sources, and it is desirable that a part of the protein should be of animal origin.

During growth, pregnancy, and lactation, some animal protein is essential, and in the growing period it should form a large proportion of the total protein.

The following allowances of total protein are recommended:

Age (years).	Grammes per kilogramme of body-weight.
1-3	3.5
3-5	3.0
5-15	2.5
15-17	2.0
17-21	1.5
21 and upwards	1.0

Women			
Pregnant	2.0		
Nursing	2.0		

All the above figures on which the Commission has agreed are average values and it is essential that they should be interpreted in the light of this fact.

FAT REQUIREMENTS

Fat must be a constituent of the normal diet, but the data at present available do not suffice to permit a precise statement of the quantity required.

In cold climates the energy-content of the diet should be increased.

PART II

Mineral and Vitamin Requirements

The Commission recognises the fact that the deficiencies of modern diets are usually in the *protective foods* (foods rich in minerals and vitamins) rather than in more strictly *energy-bearing foods* (rich in calories). Among the former are, first and most important, milk and milk products, eggs and glandular tissues; then green-leaf vegetables, fruit, fat fish, and meat (muscle). Among the energy-bearing

foods of little or no protective power are sugar, milled cereals, and certain fats.

Of energy-giving foods, unmilled cereals are not rich in protective nutrients and the more they are refined the less is their protective power. Many fats, especially when refined, possess little or no protective constituents. Refined sugar is of value only as a source of energy; it is entirely devoid of minerals and vitamins. The increasing habit of large sugar consumption tends to lessen the amount of protective foods in the diet and is to be regarded with concern.

REQUIREMENTS OF PREGNANCY AND LACTATION

The Commission has attempted to define the quantitative needs of protective foods for perfect nutrition in terms of the requirements for the pregnant and nursing woman. She should be regarded as the member of the population needing the greatest "protection" in order to ensure adequate physical endowment for the child at birth and optimum nutrition during infancy.

The greatest difficulty in arranging such a diet is to provide adequate calcium, phosphorus, iron, and vitamins B₁, B₂, C, and D.

Milk, whole or skimmed, is a rich source of calcium salts and phosphates and of vitamin B₂, also a good source of vitamin B₁; milk fat is an excellent source of vitamin A. Eggs contain vitamins A, B₁, B₂, and D and are rich in iron. The proteins of these foods are not only themselves of the highest nutritive value, but also improve the utilisation of the protein contained in cereals and vegetables. Milk has an additional advantage in the abundance and availability of its calcium salts and phosphates; these enhance the effect of any vitamin D derived from other articles of diet or from sunshine. Milk, although itself poor in iron, renders more effective the iron contained in the diet.

Ordinary diets are usually inadequate in vitamin D and, except in sunny seasons and sunny countries, a small daily ration of cod-liver oil is to be recommended in the diet of the pregnant and nursing mother and in that of the growing child. Fish-liver oils are the richest known natural sources of vitamin A and are also important sources of iodine. In goitrous regions, where sea-fish are not available, the provision of extra iodine in the form of iodised salt or in some other way is recommended.

An extended dietary use of the potato is recommended to replace part of the sugar and highly-milled cereals in the ordinary diet. Potatoes provide extra vitamin C and more readily available calcium and phosphorus than are present in cereals. Potatoes also yield more iron and B vitamins than milled cereals.

The above paragraph applies to countries where potatoes are abundant, but it is of general application, due account being taken of local resources.

REQUIREMENTS OF OTHER ADULTS AND CHILDREN

Tables I., II., III., and IV. contain details of specimen diets derived from investigations made in Great Britain, the United States, and Scandinavian countries, considered satisfactory for a pregnant or nursing woman and for infants and children of ages up to 5 years. They are put forward as models which could be modified in many particulars according to national dietary habits and supplies, provided that the dietary principles contained in them are duly regarded.

The protective foods in Table I. are arranged to yield approximately 1400 calories without inclusion of cereals, fats, or sugar; these can be added as

 (e) Calculated as beans.
 (f) Calculated as white flour.
 (g) Calculated as whole wheat.

TABLE II.—Infants

AGE 0-1

Breast-feeding is strongly recommended during the first nine months of life. Where and when sunshine is not abundant, each breast-fed infant should receive a small daily ration of cod-liver oil, up to 6 grammes daily, to supply the antirachitic vitamin D. This is even more important for artificially fed infants. Fresh fruit and/or vegetable juice to provide antiscorbutic vitamin C should also be given to every infant, especially the artificially fed.

When breast-feeding is not possible, the basis of the infant's diet should be milk, suitably modified if necessary, and supplemented by an adequate amount of substances rich in vitamins A, C, and D.

Where complete breast-feeding is impracticable, partial breast-feeding is urged, and the supplementary diet should consist of cow's milk and other suitable protective foods.

AGE 1-2 (1000 CALORIES)

A.—Protective Foods

Food.	Amount (grammes).	Calories.	Protein (grammes).
Milk	1000	660	32
One egg (or equivalent, as 30 grammes meat or fish or liver, if available)	48	70	6
Green leafy vegetables	30-60	15	—
Potato (and other root vegetables)	50	50	1
Cod-liver oil	3	30	—
A source of vitamin C (raw vegetable or fruit)	—	—	—
Total		825	39

B.—Supplementary Energy-yielding Foods

Fats (butter if possible)	3.5	25	—
Cereals (as wheat)	50	150	7
Total		1000	46

TABLE III

AGE 2-3 (1200 TO 1300 CALORIES)

A.—Protective Foods

Food.	Amount (grammes).	Calories.	Protein (grammes).
Milk	1000	660	32
One egg (or equivalent, as 30 grammes meat or fish or liver, if available)	48	70	6
Green leafy vegetables	60-100	20	2
Potato (and other root vegetables)	100	100	2
Cod-liver oil	3	30	—
A source of vitamin C (raw vegetable and fruit)	—	—	—
Total		880	42

B.—Supplementary Energy-yielding Foods

Fat (butter if possible)	3.5	25	—
Cereals (as bread)	100	300	14
Total		1205	56

TABLE IV

AGE 3-5 (1400 CALORIES)

A.—Protective Foods

Food.	Amount (grammes).	Calories.	Protein (grammes).
Milk	1000	660	32
Egg	48	70	6
Meat, fish, or liver	30	40	6
Green leafy vegetables	100	30	3
Potato	150	150	3
Cod-liver oil	3	30	—
A source of vitamin C (raw vegetable or fruit)	—	—	—
Total		980	50

B.—Supplementary Energy-yielding Foods

Fats (butter if possible)	7	55	—
Cereals (as bread)	125	400	17
Total		1415	67

required to satisfy the energy requirements of any individual. For adults other than the pregnant and nursing woman, the amount of protective foods might be reduced, if necessary, for economic reasons. For growing children, however, the maintenance of a high proportion of protective foods should be the aim.

In Tables II., III., and IV., specimen diets are drawn up on the above basis for age-groups, 0-1, 1-2, 2-3, and 3-5 years. Since the rate of growth of a child decreases with advancing age, approximately the same amount of the protective foods will suffice for 10-15-year-old children as is required for the 5-year-old child.

GENERAL RECOMMENDATIONS

Although a *simplified* diet may be so constituted from a few protective foods as to be satisfactory, it is a general principle that *variety in diet* tends to safety, provided it contains a sufficiency of the protective types of food materials.

White flour in the process of milling is deprived of important nutritive elements. Its use should be decreased and partial substitution by *lightly milled cereals* and especially by *potatoes* is recommended. The consumption of an excessive amount of *sugar* is to be condemned, and in this case also partial replacement by *potatoes* is urged.

Milk should form a conspicuous element of the diet at all ages. The Commission commends the tendency manifested in some countries to increase the daily intake up to one litre per day for pregnant and nursing women, as well as to provide an abundant supply for infants, children of all ages, and adolescents. The practice of providing milk either free or at a reduced price to these is highly recommended. The Commission desires to draw attention to the high nutritive value of *skimmed and separated milk*, which, although deprived of its vitamin A through removal of the fat, retains the protein, the B and C vitamins, the calcium and other mineral elements. The Commission deplores the large wastage in many countries of this valuable food.

Fresh vegetables and/or fruit should always be constituents of the normal mixed diet. Adequate provision of the vitamins other than vitamin D can be readily accomplished by inclusion in the diet of optimum amounts of protective foods. Where these are not available, only such *vitamin preparations* as are *officially controlled and approved* should be permitted.

The Commission emphasises the need for provision of *extra vitamin D*, either as cod-liver oil or as irradiated products, wherever and whenever sunshine is not abundant, especially in the period of growth and during pregnancy.

PROBLEMS RECOMMENDED FOR FURTHER STUDY

1. Assessment of the nutritional state of children.
2. Nutritive food requirements during the first year of life.
3. Minimum vitamin and mineral requirements.
4. Minimum fat requirements.
5. The nutritive and "supplementary" values of the different protein-containing foods, to determine to what extent and in what forms animal protein is necessary for growth and health.
6. The relative nutritive value of different cereals according to the degree of milling.
7. The extent to which the increasing consumption of sugar is detrimental to health.
8. Influence of climate on food requirements.
9. The extent to which diets in common use fall below the standards recommended in this report.

MEDICINE AND THE LAW

Impersonating a Registered Practitioner

Ernest Pearce Freeman, who had posed as a doctor, was sentenced to four years' penal servitude at Birmingham assizes last week. The gist of the charges against him was that he had represented himself to be a Dr. Louis Rabinov and to possess the professional qualifications shown against Dr. Rabinov in the Medical Register Colonial List. Freeman had bought and successfully conducted a medical practice at Hall Green, Birmingham; he had also obtained clothes from a Birmingham tailor, drugs from a chemist, and a car from a motor dealer in the name of Dr. Rabinov and in circumstances which justified the jury in finding him guilty of false pretences and forgery. He pleaded guilty to illegalities in respect of dangerous drugs. A charge of bigamy was, at his request, taken into account by the court in passing sentence. Further charges of indecent assault arose out of Freeman's treatment of women patients who believed themselves to be consulting a genuine doctor. This aspect of the case recalls the old ruling in *R. v. Rosinski*, where it was held that an assault was committed when a man, professing to act as a medical adviser, fraudulently induced a girl to strip by falsely alleging that it was necessary for medical reasons to do so. It was contended on Freeman's behalf that he had done nothing to his women patients except in the course of treating them as a doctor would have done. With the judge's consent, the prosecution did not proceed with these charges of indecent assault.

The remarkable adventures of Freeman, partly given in evidence during the trial and partly supplied by the police after his conviction, had included some connexion with medicine. He left his home in Belfast at the age of 14 and went to America. A claim to have qualified at the Chicago College of Medicine was not substantiated by police inquiries. In 1915 he returned to England and served overseas with the Royal Fusiliers, being discharged in 1917 with a very good character. He went back to the United States and claimed to have acted as assistant to a doctor in Utah and to have worked in the State hospital. He left this post with moneys stated to have been fraudulently collected and returned to England. In 1922 he married; next year he absconded from a firm in Newcastle and re-entered America with a false passport in the name of Kenneth McLennan. Working in Buffalo as an office manager and salesman, he stole and filled in blank cheques and drew the money. Convicted for these offences, he was deported and he landed in Glasgow in 1925. Presently he was arrested for a former embezzlement at Newcastle and went to prison for three months. On release he became manager of a London dance hall, but he falsified accounts and embezzled money, with the result that he went to prison for another 12 months. Later he was heard of at Singapore, obtaining money there for the formation of a company. In March, 1934, he was at Melbourne where he made the acquaintance of Dr. Louis Rabinov, a practitioner with Australian and Irish degrees. He told Dr. Rabinov that his own family in Belfast had known Mrs. Rabinov in Dublin. Dr. Rabinov seems to have summed up his visitor as an impostor and he suspected him of carrying off a copy of his diploma. In September Freeman came back to England and acted as locum tenens to doctors in London and on the South Coast. He then, in answer to an advertise-

ment, bought a medical practice at Hall Green, Birmingham. He showed the vendor a letter which was a striking testimonial to Dr. Rabinov from the Anglo-Austral Chemical Co. Ltd., signed "E. P. Freeman, Managing Director." At Birmingham he had the impudence to put up a plate calling himself "Dr. Louis Rabinov, M.B., B.S. (Melbourne), D.G.O. (Dublin)"; on the wall of his surgery was a diploma purporting to have been given to Dr. Rabinov in Melbourne. Witnesses described Freeman as a man of forceful personality. There was evidence that he actually increased the practice he had bought. When he took it over in 1934 there were 24 panel patients; in the following January there were 84 and in April 1935. There were subsequent negotiations for the resale of the practice. He had lately purchased an hotel at Cowes, describing himself as Dr. Richard Grant, lately arrived from abroad.

Whatever Freeman's medical qualifications may have been, Mr. Justice du Parc passed sentence on him as "a crafty criminal and a danger to society." Members of the medical profession will probably be startled at the ease with which a rogue can adopt the identity of a registered practitioner. There have been other instances in the past few years of this kind of fraud, the criminal sometimes taking advantage (like Freeman) of the remoteness of his victim's place of practice, and sometimes taking one of the commoner surnames on the Register with the obvious hope of making his identification more difficult. The case suggests that, in dealings with strangers—e.g., in engaging a locum tenens, taking a partner, or selling a practice—no precaution should be spared, though it is hard to see how the false Dr. Rabinov could have been unmasked without more detective research than the average practitioner has time for.

Naturopath and Illegal Operation

Another case at the Birmingham assizes was that in which John Wilson, who described himself as a naturopath and osteopath with American training, was found guilty of criminal abortion. The offence was committed upon a young woman who had acted as his "receptionist." In the judge's view the jury's verdict meant that the girl's story of Wilson's relations with her was to be believed in spite of his denials. The details of the case are of no special interest except for certain observations of Mr. Justice du Parc. There was no suggestion that Wilson was a professional abortionist or that he had posed as a registered practitioner. But the judge pointed out that the medical knowledge claimed by the accused made the offence more serious because he must have known the dangerous consequences. Fortunately the medical treatment which the young woman afterwards received had saved her life; otherwise, said the judge, Wilson would have been standing his trial for manslaughter at least.

THE fifth attempt on Mount Everest will be made next year under the leadership of Mr. Hugh Rutledge. In 1933 the party consisted of 16 men, but this time the number has been limited to 12 to reduce difficulties of portage. The final medical examination of picked candidates was carried out by the central medical establishment of the Royal Air Force and the selected 12 include Dr. C. B. Warren, Dr. Noel Humphreys, and Mr. F. H. L. Wigram, a medical student at St. Thomas's Hospital.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. C. M. R. Thatcher to *Pembroke* for R.N. Hospital, Great Yarmouth.

Surg. Comdrs. H. L. Douglas to *Pembroke* for R.N.B.; H. E. Scargill to *Excellent*; A. H. Joy to *President* for R.N. College, Greenwich; C. H. M. Gimlette to *Pembroke* for R.N. Hospital, Chatham; and J. C. Kelly, D.S.C., to *Amphion*.

Surg. Lt. Comdr. T. C. H. Neil to rank of Surg. Comdr. Surg. Lt. Comdrs. J. Johnston to *Curacoa*; H. J. McCann to *Victory* for R.N.B.; S. J. Savage to *Drake* for R.N.B.; E. T. S. Rudd to *Dolphin*; and L. P. Spero to *President* for course.

Surg. Lt. G. D. Wedd to *Scarborough* (on recommg.).

Surg. Comdrs. (D). W. C. Murray, O.B.E., and J. F. Place to rank of Surg. Capt. (D).

Surg. Lt.-Comdrs. (D). A. Dally, A. D. McHaffie, A. Macpherson, and J. T. Wood to rank of Surg. Comdr. (D).

ARMY MEDICAL SERVICES

Col. T. S. Blackwell, late R.A.M.C., retires on ret. pay. Lt. Col. J. A. Renshaw, from R.A.M.C., to be Col.

ROYAL ARMY MEDICAL CORPS

Maj. P. J. Ryan, M.C., to be Lt.-Col.

Short Serv. Commissions.—Clayton Henry George to be Lt. (on prob.) and confirmed in his rank. (Substituted for notices in *THE LANCET* of August 31st and Nov. 2nd.)

Lt. J. M. Carnow to be Capt.

REGULAR ARMY RESERVE OF OFFICERS

Lt.-Col. A. M. Pollard, D.S.O., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY

Capt. E. White to be Maj.

O. T. Wade (late Cadet Lee.-Corpl., Repton Sch. Contgt., Jun. Div., O.T.C.) to be Lt.

ROYAL AIR FORCE

Squadron Leaders J. D. Leahy, M.C., to R.A.F. Station, Calshot, for duty as medical officer; W. J. G. Walker to No. 7 Flying Training School, Peterborough, for duty as medical officer; and T. J. X. Canton to R.A.F. Station, Manston, for duty as medical officer.

Flight Lt. G. H. J. Williams to Aeroplane and Armament Experimental Establishment, Martlesham Heath.

Flying Offrs. P. A. Cooper to No. 1 School of Technical Training (Apprentices), Halton; T. J. M. Gregg and R. L. Soper to Princess Mary's R.A.F. Hospital, Halton; R. S. B. McClean to R.A.F. Hospital, Cranwell; L. N. Trethowan to R.A.F. Station, Bircham Newton; A. S. Amsden to No. 7 Flying Training School, Peterborough; H. E. Bellringer to Home Aircraft Depot, Henlow; C. M. Carlyle-Gall to Central Flying School, Upavon; R. A. Cumming to No. 11 Flying Training School, Wittering; W. J. L. Dean to No. 2 Flying Training School, Digby; S. R. C. Nelson to No. 6 Flying Training School, Netheravon; R. S. Peill to No. 5 Flying Training School, Sealand; and J. B. Wallace to R.A.F. Depot, Uxbridge.

NUNEATON GENERAL HOSPITAL.—The annual report of this hospital shows that its income is £10,700, and is mainly derived from the weekly contributions of work-people. The balance of income over expenditure is £1050, but £1000 will have to be spent to meet the cost of a new maternity ward which is badly needed.

INGHAM INFIRMARY, SOUTH SHIELDS.—On Dec. 7th Sir James Roundhead opened the new buildings at this hospital, which include a ward block, out-patient department, two operating theatres, kitchens, and an enlargement of the nurses' home. The extensions will eventually cost £60,000, and over £11,000 is still required. With the new extensions the hospital now has 183 beds.

OBITUARY

WALTER SYDNEY PERRIN, M.Chir. Camb.,
F.R.C.S. Eng.

Mr. Perrin's death on Dec. 8th was unexpected, for he had continued his work at the London Hospital until a fortnight before. He was an able surgeon and a man learned in many directions; and the ending of his life at the early age of 53 will be deeply regretted by his associates and those who enjoyed his friendship.

The son of Walter Perrin, he was educated at the City of London School and at Cambridge, where he was a foundation scholar of Caius College, and was

placed in the first class in both parts of the Natural Sciences Tripos. At this time he had no intention of taking up medicine, and for ten years his attention was given chiefly to the study of protozoa. Beginning in 1900 with publication of researches on the life-history of one of the trypanosomes, he secured the Walsingham prize and the Shuttleworth research studentship, and in 1905 was appointed university demonstrator in zoology

MR. PERRIN

—a post he was to hold for five years. In 1910, at a stage when his career as a zoologist had already shown performance as well as promise, he was obliged to seek a more remunerative occupation, and he set himself to qualify as a doctor. To fulfil this end he had to support himself by teaching others, including fellow candidates, and his skill as coach won him a great reputation. While still a student he became demonstrator in anatomy at the London Hospital in 1910, and he continued this work until he qualified in 1912, winning on the way the surgical and medical scholarships—and incidentally maintaining his prowess as a boxer. House appointments followed, both at his own hospital and at Great Ormond-street, and the outbreak of war found Perrin surgical registrar at the London, where he had lately won the triennial Jonathan Hutchinson prize for an essay on intussusception. He had also become F.R.C.S. and had taken the Cambridge degree of master of surgery, and these qualifications brought him the command of the Belgian Field Hospital at Furnes, and later the post of surgical specialist in the R.A.M.C. with rank of major. Returning to the London after the war he became first assistant in the surgical unit, and in 1921 was elected to the staff. Besides his surgical work he continued for a time to lecture in anatomy, and he so far retained his interest in this subject that eighteen months ago he was invited to serve on the board of electors to the anatomy chair at Cambridge, where he was an examiner in surgery. A keen freemason, he was a member of the staff

of the Royal Masonic Hospital, and he was also consulting surgeon at King George's Hospital, Ilford, and the Finchley Memorial Hospital.

As a surgeon Perrin's interests turned increasingly to rectal diseases, and he held office as president of the subsection of proctology of the Royal Society of Medicine. Mr. Hugh Lett, to whom we are indebted for biographical details, writes that his "careful investigation of his cases, sound judgment, operative skill, and unremitting care, leavened with a full measure of kindly sympathy, brought him a reputation which may be estimated by the frequency with which his colleagues and other members of the profession sought his advice for their relatives or themselves. Ever alive to surgical progress he weighed each new theory or practice in the scales of a cautious criticism based on wide experience, and adopted what he found good." As a teacher "his retentive memory, his grasp of any subject that he studied, and his extraordinarily clear and simple exposition, illustrated by clever draughtsmanship, smoothed away the difficulties of his students, impressed essentials on their memory, and conjured an ordered sequence out of unintelligible chaos." The draughtsmanship was associated with deep interest in many forms of art, while the gift of logic had been fostered by the continuing study of Latin and Greek literature.

Mr. Perrin married Dorothy, daughter of F. P. Rafferty, and she survives him with three children. His eldest son has lately gone to Cambridge.

ROBERT ARTHUR ASKINS, M.D. Dub., D.P.H.

WE regret to record the death of Dr. R. A. Askins which occurred on his return journey to South Africa to resume his appointment as principal medical officer to the Government of Southern Rhodesia. Dr. Askins was born at Clonmore Rectory, Co. Louth, was educated at King's School, Warwick, and studied medicine at Trinity College, Dublin, where he qualified in 1907 with first-class honours. After residence at Sir Patrick Dun's and the Children's Hospitals, Dublin, he entered the public health service as assistant medical officer for Merthyr Tydfil, and then for five years assistant school medical officer for the County of Lancaster. In 1914 the Bristol education committee made him its first full-time medical officer and for ten years—with a break as specialist sanitary officer, 1915-19, with the B.E.F.—he organised the school service in Bristol with such ability that in 1924 he was appointed deputy M.O.H. for the city and port, and in 1928 succeeded Dr. D. S. Davies in that capacity, retaining also the school medical work in his hands. One of his particular interests was children's vision, and he made an important report on the age-incidence of myopia in public elementary schools. He had already taken the D.P.H. Camb. and had been admitted to the bar, and his organising ability prepared the way for the wide changes in Bristol hospital management resulting from the Local Government Act of 1929. His resignation in May, 1930, on appointment to Rhodesia, caused much regret in Bristol where he was universally respected. Outside his official work Dr. Askins was of a shy and retiring disposition, fond of rural life, and spending his leisure in the hills of Somerset and Gloucester. He leaves a widow and two young children.

ROBERT NESBITT, L.R.C.P.I., J.P.

Dr. Nesbitt, who died at Sutton-in-Ashfield, Notts, on Nov. 26th, in his eightieth year, had practised for over half a century in the town. A native of Corglass, Co. Monaghan, he received his early education at Ballybay. A leaning towards medicine brought him as a lad of 17 to the old Ledwich school of medicine in Dublin, where at the age of 21 he took the L.R.C.S.I., L.K.Q.C.P.I., and L.M. After three years as house surgeon at Monaghan Infirmary in 1882 he married and settled at Sutton-in-Ashfield, where he remained all his life, although he retired from

active practice in 1927. As M.O.H., district medical officer, public vaccinator, certifying factory surgeon, medical officer to the Post Office, railway companies, and collieries, and referee to several insurance companies he led a busy life. Nominated to the county bench in 1894 he was its chairman for some time. During the late war he presided over the local tribunal. He visited the U.S.A. on five occasions, partly to enlarge his family tree, and in 1930 he brought out privately a history of the Nesbitt family. Three years ago he celebrated his golden wedding. He leaves a widow, three daughters, and a son in the legal profession.

PUBLIC HEALTH

The Health of the School Child

THE annual report of the chief medical officer of the Board of Education is one of the most remarkable socio-medical products of our time. For twenty-seven years it has been signed by Sir George Newman; the report for the year 1934 which records work done under his direction and supervision is presented by Dr. Arthur MacNalty who is responsible for the report as a whole, although he states frankly in his introductory note that it is a composite document. It is in fact a series of monographs on various aspects of child life and of the relation of medical and social agencies thereto. An appendix to the report tells us who are the medical officers of the Board of Education who have contributed to it, although it does not enable us to associate the name with the chapter. The names are as follow: senior medical officer: Dr. J. Alison Glover; medical officers: Dr. Muriel Bywaters, Dr. A. H. Gale, Dr. J. E. A. Underwood, Dr. Robert Weaver, L.D.S., Dr. Ralph Williams (who is also chief examiner in hygiene), and Dr. Lilian Wilson. Dr. MacNalty calls special attention to the first two chapters on nutrition and physical training. It is, he remarks, important that full use should be made of the services of preventive medicine; otherwise zeal for either form of culture may outrun discretion. The tired brain of the child may be rested by diversion to more physical exercises and open-air recreation; but should the diversion be carried too far two body-systems may be overworked instead of one. Conversely the boy or girl who is overpressed in physical exercise or sport may suffer from exhaustion which reacts unfavourably upon mental capacity. Whatever form training may take it must be proportional to the age, sex, habits, circumstances, and state of health of the individual child or adolescent. In this important work, Dr. MacNalty concludes, the school medical officer should be able to render yeoman service.

In the chapter on nutrition it is said that whilst subnormal and bad nutrition (or malnutrition) are impossible to define precisely, yet it is not difficult for a medical officer of experience, tact, and common sense to make an assessment of a child's nutrition sufficiently accurate for practical purposes. In every collection of children however well-fed and circumstanced some, perhaps 4 per cent., will appear of subnormal nutrition. The fact that such children will always be found does not however invalidate the statement that the main factor in the production of subnormal nutrition in children is poverty. Poverty does not necessarily imply actual lack of food, but it is the root cause of nearly all the other factors which produce subnormal nutrition—overcrowding, lack of ventilation in sleeping quarters, lack of fresh

air otherwise, poor school buildings, short hours of sleep, lack of cooking facilities, high incidence of and delayed convalescence from infectious disease. Poverty powerfully influences the quality of the diet, cutting down the proportion of the protective foodstuffs—e.g., milk, eggs, butter, vegetables (especially green vegetables), and meat. Even the strain of home-work is undoubtedly greater the poorer the home, and it may be a "poverty" factor in the older children. It is good to note that in last Monday's circular to local authorities the Board of Education makes it clear that extra meals may properly be provided free "for any child who shows any symptoms, whether educational or physical, however slight."

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 7TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2698; diphtheria, 1317; enteric fever, 29; acute pneumonia (primary or influenzal), 838; puerperal fever, 32; puerperal pyrexia, 95; cerebro-spinal fever, 24; acute poliomyelitis, 5; acute polio-encephalitis, 1; encephalitis lethargica, 8; continued fever, 1 (Chorley, Lancs); dysentery, 39; ophthalmia neonatorum, 66. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Dec. 13th was 3387, which included: Scarlet fever, 1157; diphtheria, 1281; measles, 147; whooping-cough, 303; puerperal fever, 22 mothers (plus 13 babies); encephalitis lethargica, 279; poliomyelitis, 6. At St. Margaret's Hospital there were 17 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (1) from enteric fever, 27 (1) from measles, 2 (0) from scarlet fever, 14 (0) from whooping-cough, 36 (5) from diphtheria, 50 (13) from diarrhoea and enteritis under two years, and 45 (5) from influenza. The figures in parentheses are those for London itself.

Manchester reported 10 deaths from measles, Liverpool 6, Blackburn and Preston each 2. Liverpool had 3 fatal cases of whooping-cough, Birmingham and Nottingham each 2. The deaths from diphtheria were reported from 24 great towns: 8 from Liverpool, 2 from Carlisle, not more than 1 from any other large town. The mortality from influenza is scattered over 31 great towns. Liverpool reporting 3.

The number of stillbirths notified during the week was 237 (corresponding to a rate of 39 per 1000 total births), including 32 in London.

VICTORIA CENTRAL HOSPITAL, WALLASEY.—Lord Moynehan has opened new twin operating theatres at this hospital. Other recent improvements include the extension of the X ray department and the enlargement of the male ward. In all, the expenditure has been about £18,000.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Voluntary Hospitals (Paying Patients) Bill

IN the House of Lords on Dec. 10th Lord LUCKE moved the second reading of the Voluntary Hospitals (Paying Patients) Bill. The Bill received a second reading in the House of Commons last July, but there was no time, he said, for its passage through its later stages. In moving the second reading of the Bill now, he desired merely to clarify the considerations which animated those responsible for its introduction and to remove certain misconceptions.

The object of the Bill was to put all hospitals on a level so far as possible in their power to meet certain present-day needs. Voluntary hospitals with modern trust deeds had no legal hindrance to prevent them from providing for all classes who needed hospital treatment. Their primary function was to provide beds for the sick poor in the comparatively small number of pay beds for the black-coated poor of the term. They often provided a comparatively small number of pay beds for the black-coated poor and the middle and professional classes, who were not able to pay a moderate weekly charge, but could not afford what they would have to pay elsewhere. They sometimes also provided a still smaller number of beds for patients who needed treatment which, however well off they might be, those patients were often unable to obtain anywhere except at a hospital, and who were charged at rates appropriate to their means. The need of this new service resulted partly from the modern developments of later and expensive methods of diagnosis and treatment, and partly from recent economic changes which had produced what were called the New Poor. These new services had been provided in addition to and not in elimination of the maintenance and existence of the ordinary beds. In some hospitals the trust deeds were settled long ago when medical treatment was a very simple and inexpensive affair, and hospital accommodation was only needed by the very poor. The result was that at some hospitals these ancient trusts were so worded that the hospital could not legally provide for any patients of the term even with money specially original sense of the term for the purpose, and if the collected or received for to treat any other patients, pital had occasionally were unobtainable elsewhere, because the treatments were charge them what they it had no legal power to charge if it did not do it at were able to pay. Nor could it provide special accommodation for them even if it did not do it at a profit. It was certainly hard on the older hospitals not to be able to provide these modern facilities which some other hospitals could provide. It was also hard on particular neighbourhoods not to be able to enjoy those modern facilities which other neighbourhoods could enjoy.

The object of the present Bill was to give the Charity Commissioners power in suitable cases to remove these anomalies by enabling such hospitals to provide pay beds as long as it was not done at the expense of or to the detriment of the primary work which they were doing of providing for the sick poor. The Bill contained ample precautions against any risk that trusts for the direct benefit of the sick poor would be disregarded. In addition to the control given to the Charity Commissioners, there were special safeguards introduced in the Bill last session by the Government to ensure that funds could not be diverted to any other purpose. In actual practice experience showed that the provision of pay beds benefited the whole community, including the sick poor themselves. The hospital with pay beds served patients who would otherwise be unable to obtain the latest treatment and who then became grateful supporters. Patients who could afford to pay could be charged what they could afford, and there was then an actual profit which helped the hospital to

carry on its ordinary work. There could be no fear that anything in the Bill would enable hospitals to diminish their work for the sick poor, even if they wanted to do so. The safeguards in the Bill would prevent them from reducing their ordinary work, but the powers given by the Bill would assist them to increase it.

Viscount GAGE, speaking on behalf of the Government, said that when the Bill was first introduced the Government considered that, provided that certain precautions were put in with the object of maintaining the existing trusts, they could thoroughly support the measure. Those amendments to secure that the objects of the original trusts were maintained and the rights of the poorer patients were safeguarded, were agreed between the promoters and the Government and appeared in this Bill. In those circumstances the Government were fully in support of the Bill.

The Bill was read a second time.

Improvement of Health Services

IN the House of Commons on Dec. 10th Sir KINGSLEY WOOD, Minister of Health, replying to the debate on the Address, said that the health proposals were very germane to the discussion, because their plans were of very little value unless they were able to build on the foundation of a healthy nation. It was for that reason that the Government had given prominence in their programme to the importance of social and public health services. Referring to the Government's proposed legislation for the improvement of the midwifery service, Sir Kingsley said there was urgent need of a sound midwifery service to ensure to every woman who required it skilled care in childbirth. A Bill was now being drafted and the Government hoped to introduce it early next year. In the interval he would consult with the appropriate associations, including representatives of the important voluntary associations who were engaged in this important work. There were very obvious gaps in the system of health insurance between the time that boys and girls left school and the time when they entered into insurable employment. There was also the difficulty in the present national health insurance and contributory pension scheme that many people at work on their own account were unable to enter into the insurance and pension system although their circumstances did not differ from other insured persons. The Government would introduce legislation to deal with these important matters.

HOUSE OF COMMONS

WEDNESDAY DEC. 11TH

Restriction of Medical Licences in Palestine

MR. TOM SMITH asked the Secretary of State for the Colonies whether, in view of the protests of the Jewish agency against the restriction of medical licences in Palestine to persons who were naturalised and the fact that a number of Jewish doctors of German nationality were anxious to set up practice in Palestine, he would state the reason for the promulgation of the Ordinance restricting medical licences in this manner.—Mr. J. H. THOMAS replied: The Medical Practitioners (Amendment) Ordinance 1935, places no restriction on the number of licences to practise medicine which may be granted to Palestinian citizens by birth or persons who became Palestinian citizens or received permission to remain permanently in Palestine on or before Dec. 1st, 1935. The quota restriction imposed by the Ordinance affects only persons who became Palestinian citizens or received permission to remain permanently in Palestine after that date. Further, persons who will be employed solely in the practice of medicine in or on behalf of any recognised medical or scientific institution will be exempt from the quota. The reason for the enactment of this Ordinance

was that, in view of the great influx of medical practitioners in recent years, the profession was becoming overcrowded, a situation which had given rise to abuses, and had seriously affected the livelihood of established and reputable practitioners.

Colonel WEDGWOOD: Is the right hon. gentleman aware that the established recognised medical practitioners did not ask for this Ordinance, and that it affects merely the unfortunate refugees from Germany?

Mr. THOMAS: I am aware of the fact that there were a certain number of medical practitioners in Palestine, that owing to the unfortunate circumstances in Germany there was a large influx of others, and that those engaged in the medical profession asked for some protection for their position.

Medical Rejections of Air Force Recruits

Mr. POTTS asked the Under-Secretary of State for Air the number of persons who presented themselves for recruitment into the Royal Air Force for the year 1934 and the number rejected upon medical grounds or other causes.—Sir P. Sassoon replied: During the year ended March 31st, 1935, 16,389 definite applications for enlistment into the Royal Air Force were received: 7085 of these applicants were medically examined, 2786 were found medically fit and 2347 were attested.

THURSDAY, DEC. 12TH

Voluntary Hospitals in the Special Areas

Mr. STOREY asked the Minister of Labour whether the commissioner for the special areas was now prepared to make grants to the governing bodies of voluntary hospitals in the special areas towards the cost of the provision of new or the extension or alteration of existing hospitals or out-patient departments in the same way as he was prepared to make such grants to local authorities.—Mr. E. BROWN replied: Yes, Sir. The Commissioner is prepared to consider applications of this kind and to make grants on certain conditions.

Old Books and Infectious Disease in Schools

Mr. ANDERSON asked the President of the Board of Education how many school books under the control of the Cumberland Education Committee had been in constant use for one year, two years, three years, and over three years respectively; and whether his department had any particulars of the effect of the continuous use of old school books upon the spread of infectious diseases in schools.—Major DAVIES (Vice-Chamberlain of the Household) replied: My right hon. friend regrets that he has no information on the first part of the hon. Member's question. As regards the second part, while the continued use of old and soiled books in public elementary schools is to be deplored, my right hon. friend has no grounds for suspecting that infectious diseases have spread by that means.

Analgesia and Maternity

Sir ROBERT TASKER asked the Minister of Health if he was aware that a method of giving relief to women in their confinements known as gas-and-air analgesia had been in use for two years with unqualified success in the Liverpool Maternity Hospital and the Wellhouse Hospital, Barnet, and had now been adopted in a large number of hospitals throughout the country; and if he proposed to take any action to ensure that the use of gas-and-air analgesia would be encouraged in all hospitals under the control of the public health authorities.—Sir KINGSLEY WOOD replied: I am aware that the method mentioned by my hon. friend has been in use at the two hospitals referred to, and that favourable results are claimed for it. I understand also that an investigation of this and other methods is being carried out by the British College of Obstetricians and Gynaecologists, but no findings have yet been published. On my present information, I do not consider that I should be justified in taking any action in this matter, but the use of gas-and-air analgesia is within the discretion of the responsible medical officers of each hospital.

Rural Water-supplies

Sir CLIFFORD FOX asked the Minister of Health whether the full allocated subsidy of £1,000,000 for the improve-

ment of rural water-supplies had now been definitely distributed; and, if so, could he state, by counties, the aggregate allocated to each one of them.—Sir KINGSLEY WOOD replied: £801,177 has been provisionally allocated to 53 counties.

Protective Respirators and Gas Attack

Mr. ACLAND asked the Home Secretary whether His Majesty's Government knew of any gas mask capable of giving to the wearer complete protection against any probable concentration of every poisonous gas which was known to the Government; and were such gas masks available to the public or likely, in the near future, to become available to the public, and in what numbers and at what prices.—Mr. G. LLOYD (Under-Secretary, Home Office) replied: The whole subject of the arrangements to be made for the provision of respirators has been under close examination for some time past. It is hoped that it will be possible to make a full statement on this subject in the near future.

Repair of Dilapidated Dwellings

Mr. DAY asked the Minister of Health whether he was aware that many houses throughout the country were becoming uninhabitable through the neglect of the owners to put them in reasonable repair; and if he would consider the introduction of legislation compelling owners of house property to spend in repairs the percentage of rents they were allowed to charge.—Sir KINGSLEY WOOD replied: The Rent Restrictions Acts contain provisions enabling a tenant to withhold so much of his rent as represents the permitted increase if his premises are not in a reasonable state of repair, and in these circumstances I do not consider that further legislation is necessary.

Post-Vaccinal Encephalitis

Mr. BROAD asked the Minister of Health what steps were adopted with a view to bringing cases of post-vaccinal encephalitis under the notice of his department.—Sir KINGSLEY WOOD replied: Notices are published in the medical press requesting medical practitioners to notify my Department of all cases of post-vaccinal encephalitis. Information is also obtained from the returns made by public vaccinators, and by the examination of all death certificates on which any reference is made to vaccination.

MEDICO-LEGAL SOCIETY: ANNUAL DINNER.—The annual dinner of this society was held on Dec. 13th at the Holborn Restaurant, when the president, Mr. C. Ainsworth Mitchell took the chair. Sir William Wilecox, submitting the toast of "Medicine and Law," said it was increasingly desirable that the medical and legal professions should be drawn closer together, in view of the part psychology was now playing in the administration of justice, and the growing tendency to attribute wrongdoing, particularly in the juvenile delinquent, to some failure in the working of the mind. Lord Dawson, responding, said the need of both lawyer and doctor was to understand human nature. The ambit of medical thought having been extended to include the operations of the mind, the medical profession was now concerned with conduct. The linkage between body and mind was to be found in the internal glands; a slight increase in the thyroid secretion, or a slight decrease in the sex hormone might produce a change in conduct so notable as seriously to influence the doctrine of responsibility. He was in favour of the appointment of medical assessors to assist the judge in difficult cases. Mr. Claud Mullins, who also responded, declared himself as a law reformer, but a hopeless one at that, because the law seemed to be busy about everything except reforming itself. He regretted that in the higher courts there was no time between conviction and sentence for enlisting the help of medicine and psychology. "The Society" was proposed by Sir Edward Tindal Atkinson and acknowledged by the president, who said the society had now nearly 400 members. "The Guests" were toasted by Mr. E. R. Bolton; Mr. John Evans, president of the Society of Public Analysts, and Dr. Robert Hutchison responded.

MEDICAL NEWS

University of Oxford

On Dec. 14th the following degrees were conferred:—

B.M.—P. E. Cresswell, R. N. B. Cridland, H. N. Davis, H. Fidler, R. B. Hickey, E. C. O. Jewesbury, W. P. Mallinson, and F. G. Ward.

Royal College of Surgeons of England

A meeting of the council was held on Dec. 12th with Mr. Arthur Burgess, senior vice-president, in the chair. Mr. E. C. Hughes, Mr. L. E. C. Norbury, Mr. Robert Milne, and Mr. P. H. Mitchiner were elected to the court of examiners, and Sir Holburt Waring was reappointed representative on the court of governors of the University of Birmingham.

It was reported that Sir Cuthbert Wallace, the president, has been appointed a member of the general council of King Edward's Hospital Fund for London for next year.

Diplomas of fellowship were granted to the following candidates:—

Doris E. O'Doherty, M.B. Lond., M. N. Chatterjee, L.R.C.P., E. W. T. Morris, L.R.C.P., W. S. Creer, M.B. Liverp., J. K. Wilson-Pepper, M.B. Camb., I. W. Matheson, L.R.C.P., Dorothy A. Sharpe, M.B. Lond., D. K. Mulvaney, M.R.C.P. Lond., P. G. Scott, L.R.C.P., H. G. Arthur, M.B. Lond., P. B. Morozov, M.B. Liverp., K. J. Gilchrist, M.B. Lond., O. S. Tubbs, M.B. Camb., S. E. Birdsall, L.R.C.P. Lond., C. H. Gray, M.B. Manch., R. F. Winckworth, M.B. Lond., Philip Baron, M.B. Cape Town, Doris B. Brown, M.B. Leeds, R. V. Parne, M.B. Camb., V. C. Snell, M.B. Lond., T. M. Tyrrell, M.B. Camb., W. R. Hutchinson, L.R.C.P., S. G. Browne, M.R.C.P. Lond., J. F. Jarvis, M.R.C.P. Lond., L. C. Oliver, L.R.C.P., A. K. Price, M.B. Lond., P. P. Sheth, M.B. Bombay, John Grocott, M.B. Lond., R. H. R. Belsey, M.B. Lond., L. E. Jones, M.B. Lond., V. P. Gupta, M.B. Lucknow, Ibrahim Magdi, M.B. Cairo, B. H. Page, L.R.C.P. Lond., H. S. Shucksmith, M.B. Leeds, F. F. Rundle, M.B. Sydney, Garthoven Williams, L.R.C.P., M. A. Falcover, M.B. N.Z., A. S. Kerr, M.B. Liverp., Thomas Beath, M.D. Toronto, J. I. M. Black, M.B. Durh., A. N. de Quadros, M.B. Bombay, W. S. Diggle, M.B. Liverp., H. T. Fleming, M.B. Dub., S. R. Gerstman, M.B. Melb., L. W. Gleadell, M.B. Melb., A. O. Green, M.D. Melb., Muriel B. McIlraith, M.B. Sydney, Ismail Mehrez, M.B. Cairo, E. W. Peet, M.B. Durh., M. Z. Siddiqui, M.B. Bombay, J. B. Somerset, M.D. Melb., and H. K. Vernon, M.B. Durh.

A diploma of membership was granted to Dorothy J. Thompson.

Licences in dental surgery were granted to the following candidates:—

D. E. Ashdown, L. C. Bellsham-Revell, Elizabeth C. Boss, A. P. Britton, John Carnaghan, G. K. Catchpole, Marjorie L. Close, C. E. Colman, J. O. C. Daniels, J. L. Deuchar, Morris Dobkin, G. R. Down, Edward Dunstan, Ronald Edwards, Montgomery Featherman, A. C. Fraser, Peter Griffin, R. G. Gwynne, E. C. Hammond, N. A. Hawkins, C. E. Henn, R. O. Holland, D. A. Ibbetson, G. E. Jackson, J. G. Jones, J. C. Keay, S. B. Kendall, R. G. Kett, J. C. Lawson, D. W. Macfarlane, M. M. MacLachlan-Hillier, E. L. Moll, J. E. C. Peacock, F. H. W. Peatfield, P. V. Peatfield, R. A. Pepper, R. S. Pook, R. P. Powell, E. C. Redfern, H. P. L. Rhodes, Howell Richards, J. B. Rodway, J. E. Rydemark, Kenneth Sharp, N. A. Siggers, R. G. Simpson, T. A. Smitham, J. F. A. Smyth, P. W. Stanley, C. A. Stryer, Alfred Tarttelin, H. B. Thornton, A. F. Townend, P. A. Trotter, G. L. R. Welch, R. S. Wells, R. M. H. Williams, W. E. Wright, and Malcolm Wykes.

Diplomas in anaesthetics were granted jointly with the Royal College of Physicians to the following candidates:—

H. K. Ashworth, J. H. Attwood, Arnold Barnsley, C. A. Borland, Lorna Bray, H. J. Brennan, R. J. B. Broad, A. I. P. Brown, F. E. Cartwright, T. H. Chadwick, J. Davies, Winifred Dean, H. G. Dodd, N. A. F. Duggan, A. P. Gorman, R. B. Gould, H. F. Harrison, Gerald Hochschild, Mary J. Johnson, Alison R. Kerridge, L. H. Lerman, Antony Lucas, W. S. McConnell, Jean S. B. McNeil, S. V. Marshall, E. A. Marson, A. G. Miller, J. C. Nicholson, M. D. Nosworthy, E. A. E. Palmer, Brian Rait-Smith, E. H. Rink, F. W. Roberts, K. MacD. Ross, Doris M. Sanders, J. D. Scott, E. V. Slaughter, C. E. Sykes, Sheila C. H. Watters, J. H. West, Rose E. Williams, and F. C. Wright.

University of Sheffield

At a meeting of the university council held on Dec. 13th the resignation by Dr. Harold Leader of his post of lecturer in diseases of children was announced.

Faculty of Medicine.—Dr. J. W. McNee was appointed examiner in therapeutics and Prof. Daniel Dougal in obstetrics and gynaecology.

It was reported that the Rockefeller Foundation, New York, had made a grant of £200 in aid of research in the department of pharmacology.

University of London

At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B., B.S.

S. O. Aylett, King's Coll. Hosp.; Joan W. Ellinger and Mary F. Lockett, Royal Free Hosp. (with honours); R. M. H. Anning, St. Mary's Hosp.; C. G. Baker, Guy's Hosp.; T. L. S. Baynes, St. Bart's Hosp.; E. R. Bennion, Westminster Hosp.; Katherine M. Blenkins, Royal Free Hosp.; C. J. F. Blumenthal, Guy's Hosp.; P. R. Boucher, St. Mary's Hosp.; Muriel G. Boycott, Univ. Coll. Hosp.; P. E. G. Clements, St. Bart's Hosp.; J. G. Clothier, King's Coll. Hosp.; J. H. Cobb, Univ. Coll. Hosp.; E. C. Cordeaux, Middlesex Hosp.; Robert Cox, Westminster Hosp.; J. V. Dacie, King's Coll. Hosp.; D. V. Davies, Univ. Coll. Hosp.; D. G. ff. Edward, St. Bart's Hosp.; J. A. C. Franklin, St. Thomas's Hosp.; L. D. B. Frost, St. Bart's Hosp.; B. M. Goldsworthy, St. Thomas's Hosp.; K. L. Grozono, London Hosp.; E. A. Hardy, Westminster Hosp.; K. W. Hardy, London Hosp.; D. B. Hyslop, Charing Cross Hosp.; J. D. Jenkins, Middlesex Hosp.; H. S. Joseph, St. Bart's Hosp.; Charles Langmaid, Univ. Coll. Cardiff; K. A. Latter, St. Bart's Hosp.; J. I. Leeb, St. Thomas's Hosp.; J. L. Lewis, London Hosp.; M. J. Lind-ey, Guy's Hosp.; H. M. McGladdery, St. Bart's Hosp.; W. N. Mann, Guy's Hosp.; J. I. C. Mason, St. Bart's Hosp.; W. R. Merrington, Univ. Coll. Hosp.; Tudor Miles and R. L. Moody, St. Thomas's Hosp.; C. J. B. Murray, Middlesex Hosp.; Howard Nicholson, Univ. Coll. Hosp.; W. L. Ogle, Guy's Hosp.; C. J. S. O'Malley and D. A. O'Reilly, St. Thomas's Hosp.; G. H. C. Orens, St. Mary's Hosp.; W. D. Park, St. Bart's Hosp.; F. D. Paterson, St. Mary's Hosp.; Eric Pereira, St. George's Hosp.; H. N. Perkins, St. Mary's Hosp.; J. B. Phillips, Univ. Coll. Cardiff; F. O. Potter, Guy's Hosp.; W. A. Pritchard, Univ. Coll. Hosp.; J. D. Richardson, King's Coll. Hosp.; Jean Ross, Univ. Coll. Hosp.; Millicent I. Rowland, Royal Free Hosp.; P. N. Shuttle, St. Thomas's Hosp.; Isidore Sloane, London Hosp.; B. W. Smith, Guy's Hosp.; J. G. Stewart, Westminster Hosp.; J. M. Stewart, St. Bart's Hosp.; Margaret J. Sutcliffe, Royal Free Hosp.; J. W. Todd and B. McN. Tru-cott, Middlesex Hosp.; C. E. G. Wickham, St. Thomas's Hosp.; Helen E. Wight and Sheila M. R. Williams, Royal Free Hosp.; J. W. Wishart, Victoria Univ. of Manchester; A. L. Wiman, Univ. Coll. Hosp.; and E. C. Zorab, Guy's Hosp.

The following candidates have passed in one of the two groups of subjects:—

Group I.—G. T. Balean, H. L. W. Beach, L. C. Bousfield, F. E. Corea, A. G. Edwards, G. J. Evans, J. E. Giesen, W. H. Hamilton, D. T. K. Harris, Sylvia A. M. Herford, H. G. Howitt, L. M. Kelly, E. A. Knappett, H. A. Leggett, O. G. Lloyd, Queenie I. E. May, Elizabeth M. Morgan, F. J. Napier, S. G. Nardell, R. J. Niven, E. P. Rigby, R. S. F. Schilling, G. R. Taylor, W. R. Welpy, and Rowena Woolf.

Group II.—Charles Anderson, F. W. Baskerville, H. V. Brown, Kathleen E. Burnell, H. B. C. Carter-Loocke, Thomas Denness, J. E. Elliott, W. D. F. Lytle, J. McA. McArthur, E. G. Murphy, N. W. N. Murray, K. L. G. Nobbs, Dorothy S. Pope, D. A. Prothero, J. C. Roberts, E. ap I. Rosser, H. C. Thomas, Winifred J. Wadge, Alan Wardale, and E. D. H. Williams.

Aaron Meyer has passed in Part I. of the examination for the diploma in medical radiology.

University of Bristol

At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B., CH.B.

V. T. Baxter, Theodora M. Crabtree, J. G. Field, Irene G. Hamilton, and M. A. Nicholson.

University of Manchester

Mr. V. F. Lambert, hon. laryngologist to the Manchester Hospital for Diseases of the Chest and Throat, has been appointed lecturer in diseases of the ear.

At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B., CH.B.

Part II.—Jack Cohen, F. P. Ellis, William Fielding, G. D. Harthan, Henry Hempling, Ralph Mallinson, Annie Nelstrop, H. P. B. North, C. S. Parker, J. N. Shepherd, Bernard Thornley, and J. R. Wardley.

Part I.—Cyril Berens, Hélène E. K. Booth, Hilda Brice, A. H. Gregson, G. M. Komrover, W. H. Purves, and M. B. D. Welland.

Royal Institution

The subject of this year's Christmas lectures for young people is photography, and they will be given by Mr. C. E. K. Mees, D.Sc., on Dec. 28th, 31st, Jan. 2nd, 4th, 7th, and 9th, at 3 p.m. The address of the Royal Institution is 21, Albemarle-street, London, W.1.

Dr. A. G. B. Smart, senior medical officer of the Island of St. Vincent, has been appointed an official member of the executive council of the island.

Port Talbot Hospital

On Dec. 6th Lady Pollington opened the new administrative block of the Port Talbot and District Hospital, which is linked by a corridor to the main building. It includes a large sitting-room and a lecture-room for nurses.

Dairy and Ice Cream Exhibition

The sixth National Dairy and Ice Cream Convention will be held at the Crystal Palace from Jan. 28th to 31st, 1936.

St. John's Hospital for Diseases of the Skin

The out-patient department of this hospital is moving from 49, Leicester-square to larger premises at 5, Lisle-street, W.C. The new premises will be open to patients on Jan. 1st.

A Museum of Toys

The Institute of Medical Psychology, Malet-place, London, is making a permanent collection of toys from all the races of the world. Such a museum, it is thought, will be of value to the psychologist and anthropologist in tracing the early phases of social development. The Institute is receiving assistance from the Educational Branch of the Colonial Office, whose teachers in remote parts of the world select suitable exhibits from their particular area. Members of the public who can in any way help in the formation of the collection are invited to communicate with the secretary of the Institute. The toys most needed are those with an essentially national character, particularly English toys of individual non-mass-production type.

Epsom College

The 58th annual meeting of the Old Epsomian Club was held on Dec. 12th at the Hotel Great Central, with Mr. J. Norman Eggar (O.E. 1902) in the chair. Ninety-five other Old Epsomians were present, including six honorary members, and among the guests were Lord Leverhulme, president of the College, Dr. John Fawcett, treasurer, Dr. Henry Robinson, vice-chairman of the Council, Dr. H. K. D. Spitta, chairman of the executive committee, and Dr. J. A. Drake, dean of King's College Hospital medical school. As befitted the occasion, the toast list was short and the speeches brief and to the point. Sir Cosmo Parkinson proposed the health of the chairman, who, in reply, told all about cricket matches before himself proposing the toast of the evening, "Floreat Epsomia," coupled with the name of the headmaster, Rev. A. C. Powell, whom he consoled with a remark that he knew what little devils boys could be but parents could be an even greater trial. Mr. Powell spoke of two knighthoods conferred on Old Epsomians—Cosmo Parkinson (O.E. 1906) and A. J. Suenson-Taylor (O.E. 1912)—and of an even closer association between Old Epsomians and the present school by setting apart the second Saturday in July as an Old Boys' Day. Dr. Daniel Twining (O.E. 1903) proposed "The Guests" with great ingenuity, and three of them replied, Mr. John Niven, chairman of the Baltic, Dr. Fawcett, who said he had never heard so many apocryphal stories in one evening before, and Dr. Drake, who said there had never been so many openings for young doctors as there were now.

Vacancies

For further information refer to the advertisement columns

Army Dental Corps.—Commissions.
Banbury, Horton General Hospital.—Res. M.O. At rate of £150.
Bath, Royal United Hospital.—H.P. At rate of £150.
Bournemouth, Royal National Sanatorium for Consumption, &c.—Asst. Res. M.O. £200.
Cambridge, Addenbrooke's Hospital.—H.S. At rate of £130.
Canterbury, Kent and Canterbury Hospital.—Two H.S.'s Each at rate of £125.
Connaught Hospital, Wallhamston, E.—Cas. O. £100.
Crickton Royal, Dumfries.—Res. third Asst. Phys. £350-£500.
Dorchester, Dorset County Hospital.—H.S. At rate of £160.
Dover Royal Victoria Hospital.—Res. M.O. £180.
Durham, County Council, Education Dept.—Asst. School. M.O. £500.
Eastbourne, Princess Alice Memorial.—Two Hon. Surgeons. Also Res. H.S. £150.
Eastbourne, Royal Eye Hospital, Pevensey-road.—H.S. £100.

Exminster, Devon Mental Hospital.—Jun. Asst. M.O. and Pathologist. £350.
Glamorgan County Mental Hospital, Bridgend.—Jun. Asst. M.O. £350.
Great Yarmouth General Hospital.—H.S. £140.
Hammersmith Metropolitan Borough.—Two Asst. M.O.'s. Each £500.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. At rate of £50.
Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Res. H.P. At rate of £100.
Hull Royal Infirmary.—Res. Surg. O. £200.
Ilford, West Ham Mental Hospital, Goodmayes.—Jun. Asst. M.O. £350.
Kent and Canterbury Hospital.—Hon. Dermatologist.
Leeds Public Dispensary and Hospital.—Hon. Anaesthetist. Also Hon. Clin. Assts.
Leicester City General Hospital.—Jun. Asst. M.O. £300.
Liverpool Royal Children's Hospital, Myrtle-street.—Two Registrars and Tutors. Each at rate of £50.
London University.—Readership in Surgery. £800-£1000.
Manchester, Ancoats Hospital.—Res. Surg. O. £200. Also Med. Reg. £50.
Manchester Royal Children's Hospital, Pendlebury.—Res. M.O. At rate of £125.
Manchester, Withington Hospital and Institution, &c.—Jun. Asst. M.O.'s. Each at rate of £200.
Maudsley Hospital, Denmark Hill, S.E.—Research Fellowship in 1.—Tuber. M.O. £750.
Greenwich-road, S.E.—Hon. Dental

Newcastle-upon-Tyne Royal Victoria Infirmary.—Asst. to National Radium Centre. £250.
Rochdale Infirmary and Dispensary.—Sen. H.S. £250.
Royal Waterloo Hospital for Women and Children, Waterloo-road, S.E.—Hon. Clin. Asst. for Ophth. Dept.
St. John's Hospital, Lewisham, S.E.—Clin. Asst. to M.O. in Elec. and Massage Dept.
St. Mary's Hospital Institute of Pathology and Research, W.—Research Studentship. At rate of £200.
St. Thomas's Hospital, S.E.—Obstetrician and Gynaecologist.
Salford Royal Hospital.—Orthopaedic Reg. £100.
Samaritan Free Hospital for Women, Marjibone-road, N.W.—Radiologist.
Sheffield, Jessop Hospital for Women.—Sen. Res. O. Also two H.S.'s. At rate of £150 and £100 respectively.
Shoreham-by-Sea, Southlands Hospital.—Jun. Asst. Res. M.O. £250.
Southampton Borough General Hospital.—Jun. Res. M.O. £200.
Stirling District Mental Hospital, Larbert.—Third Asst. M.O. £250.
Sunderland Children's Hospital.—H.S. £120.
Westminster Hospital, Broad Sanctuary, S.W.—Three Surg. Regs. Each £250.
West Sussex County Council.—Asst. Tub. O. and Asst. M.O. £750.
Wolverhampton Education Committee.—Asst. M.O. £600.

Births, Marriages, and Deaths

BIRTHS

KINGSTON.—On Dec. 15th, at Leeds, to the wife of Frank E. Kingston, M.B.—a son.
PATERSON.—On Dec. 13th, the wife of Arthur Spencer Paterson, M.D., M.R.C.P., of Hildenborough, Kent, of a daughter.

MARRIAGES

ALEXANDER-MACKINNON.—On Dec. 12th, at St. Mark's, North Audley-street, Paul Creighton Alexander, B.M., B.Ch. Oxon., of Byfleet, Surrey, to Helen Oswald, only child of Mr. Alpin D. Mackinnon of Limsfield, Surrey.
KAUNTZ-MOODIE.—On Dec. 10th, at St. Paul's, Knightsbridge, Dr. Ralph Kauntze, to Katherine Margaret (Peggie), daughter of Mr. Ramsay Moodie of Guildford.
MITCHELL-NICOLSON.—On Dec. 11th, at St. Raphael's, Surbiton, Thomas Carlyle Mitchell, M.D., to Betty Baber Nicolson.
ROBB-SEABROOK.—On Nov. 6th, George Douglas Robb, M.D. (N.Z.), F.R.C.S. Eng., 41, Symonds-street, Auckland, N.Z., to Helen, third daughter of Mr. A. D. and the late Mrs. Seabrook of Auckland.
THURSTON-BARBEE.—On Dec. 14th, 1935, Garin Thurston, M.R.C.S., L.R.C.P., to Ione, only daughter of J. T. Barber, Esq., J.P., at St. Paul's, Winchester Hill.

DEATHS

AITKEN.—On Dec. 8th, suddenly, at Lagos, Nigeria, Andrew Blair Aitken, M.B. Glasg., F.R.C.S. Eng., Consulting Surgeon to Nigerian Medical Service.
CROSS.—On Dec. 6th, at Oxford, David Kerr-Cross, M.B. Glasg., late of id Natal, aged 78.
HERN.—On Dec. 11, idence, Beaconsfield, George Hern, 1.
OWEN.—On Dec. idnfirmay, Liverpool, M.R.C.S. Eng., of Albert Harold id Lanfairfechan, late Director of Medical and Sanitary Services, Tanganyika, aged 55.
ROXBURGH.—On Dec. 12th, at Seymour-street, W., David Roxburgh, M.B. Glasg., aged 74.
SOMERS.—On Dec. 5th, 1935, at The Grange, West Bromwich, Noble Luke Usher Somers, L.R.C.S.I., aged 73.
WOOD.—On Dec. 11th, at Manor House, Nunceaton, Alfred Arthur Wood, M.D. Liverp., aged 62.
N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

EDWARD ATSLOWE, M.D.

By R. R. JAMES

THE surname Atslove is uncommon. In Marshall's "Genealogist's Guide" the only entry at all resembling it is "Attslow," with a reference to Morant's "History of Essex." On consulting Morant (vol. i., p. 205). I find: "Henry Attslow, gent., son and heir of Edward Attslow, M.D.," as dying May 26th, 1622, possessed of the manor and advowson of Downham Kirby. in "Winchester Scholars," gives two Atslows: Ambrose and Edward; he also gives a Luke Atslove, who as a matter of fact was the younger brother of Edward.

Mr. Herbert Chitty, Bursar of Winchester College, has enabled me to give the entries from the original register of scholars which Kirby used when compiling his Roll. They are:

1547. Edwardus Atslove de Eversholde, Lincolnensis Diocesis XI annorum in festo Michaelis preterito. A marginal note gives: rec. Oxon.*

1549. Lucas Atslooe, de Eversholte comitatu Bedfordie IX annorum in festo Natalis Domini preterito. Lincolnensis (Diocesis). A marginal note gives: rec. Oxon. artium magister.

1589. Ambrosius Atslove, Sancti Oliveri (sic) London. 10 annorum. I, Maii preterito. London (Diocesis).

Kirby gives the following note under Edward's name: "Scholar New Coll. M.D. Fell. 1553-62. Removed by Queen's Commissioner." Luke appears to have been removed in 1568 because he had refused to take Holy Orders within the time laid down by the College Statutes. Foster ("Alum. Oxon.") gives Edward's degrees as follows: B.A., 1555. M.A., 1559. B.Med., 1564. D.Med., 1566. Munk ("Roll of the Royal College of Physicians") states that Edward Atslove was "on the 22nd August, 1554, actually created doctor of physic. in the house of Dr. Henry Baylie, situated in the High Street, leading to the Quadrivium, by Dr. Thomas Francis and him, the said Dr. Henry Baylie, by virtue of a commission directed to them by the Venerable Convocation." Atslove was one of four men (three of them physicians) specially appointed by Convocation to dispute before Queen Elizabeth when she came to be entertained at the University in the early part of September of that year.

Dr. Atslove was elected a Fellow of the Royal College of Physicians between 1565 and 1569. The exact date is uncertain as the records are defective for those years. He was appointed censor in 1569 for three years, and was named elect in 1572 and consiliarius in 1572 and 1583. On Nov. 2nd, 1573, he was married, at Stoke Newington, to Frances Wingfield. He was dead by May 28th, 1594, when his place as elect was filled by a much more distinguished Wykehamist, Dr. Christopher Johnson, the ex-headmaster of Winchester, well known as a poet.

Atslove was an ardent Catholic and partisan of Mary, Queen of Scots. He was twice imprisoned (in 1579 and 1585 according to the "Dictionary of National Biography") for having taken part in designs for her escape; and in a letter from Thomas Morgan to the Queen of Scots we read: "I hear that Dr. Atslove was racked twice, almost to death, in the Tower, about the Earl of Arundell his matters, and intention to depart England." Munk, from whom this is taken, says that the Earl, who died in 1595, settled an annuity on the doctor's widow.

In the "Calendar of State Papers (Domestic) Eliz." (vol. cxxxi.) occurs: 1579. June 15. Examin. of Thos. Asseley taken before Eustace Clorill esq., J.P., Essex, touching certain evidences conveyed away by Mrs. Field from Dr. Atslove's house after his apprehension.

* "Rec. Oxon." usually implies that the scholar left Winchester for Oxford to become a scholar of New College.

Dr. Atslove died intestate. Administration of his estate was granted on May 6th, 1594, to his widow, Frances. In the margin of the record is noted, "Parochie Sancti Olavi Silverstrete." This admon was granted in the probate court of the archdeacon of London (A.B., 2.148). In the third volume, p. 19, we get the compotus of the goods of Dr. Atslove on May 12th, 1595. Here he is given as of St. Olave, Hart-street. The estate seems to have been worth £361 16s. 2d.

Frances Atslove died towards the end of the year 1605. I am indebted to Mr. Herbert Chitty for the notes of her will, which follow:

Fraunces Atsloe of Downham, Essex, widow. Dated 25 Aug., 1605: proved 3 Dec., following. (P.C.C. Hayes, 89.) She desires to be buried in the parish church of Clerkenwell, near London, next to the grave where her husband was buried. She mentions her daughters Anno and Mary Atsloe; her eldest son, Henry Atsloe, her daughter Frauncis, wife of Sir Edward Frauncis, of Petworth, Sussex, Knt., and their daughter Bridget, her grandchild; her son Edward Atsloe and her son, Ambrose Atsloe, to whom she bequeathes her lease in London which she held of New College, Oxford; and her grandchild, Edward,† son of her son, Henry.

She appointed as her executors her "deare frende Mr. Doctor Oxenbridge"‡ and her son-in-law Sir Edward Frauncis. The latter proved the will.

Henry's son Edward was admitted pensioner (aged 15) at Peterhouse in 1616. He was admitted at Gray's Inn in 1618-19, and was later of Downham.

I am greatly indebted to Mr. Chitty for his generous help, and I owe to Mr. Harvey Bloom the notes on the admon of Dr. Edward.

POSSIBLE CHRISTMAS PRESENTS

Mr. H. A. Reason's ROAD TO MODERN SCIENCE¹ starts in ancient Egypt and takes us down to our own times. It is largely biographical and the reader learns about astronomy, for example, by learning about Copernicus and his successors. The contribution made to science by many different people is briefly described and we are reminded of what familiar names stand for. More than that, we are reminded of elementary principles on which the modern world is founded. While the book could be read by any well-educated person, it is particularly suited to the needs of those who have been trained in science but find it hard to explain exactly how an internal combustion engine or a barometer works. A good account is given of "waves of many kinds," but it is necessarily brief and can serve only as an introduction to such books as Prof. Andrade's brilliantly simple account of the structure of matter and radiation issued by the same publishers a few years ago.² Mr. Reason's survey is nevertheless a remarkable essay in condensation, and he is always interesting. He is shaky on the principles of immunisation (p. 243) and we do not agree that wireless waves have no effect on the human body, that Lord Lister was a Scotsman, or (unfortunately) that "to-day almost every disease, if taken in time, can be cured." But his book should appeal to many a medical man or serious-minded boy.

From the history of science we turn to the science of history, as exemplified by the reconstruction of

† The death of Henry Atslove has been given as beginning of this paper. His son Edward was 21 years of age at his father's death young, for Henry's daughter, Helen, inherited Downham and carried it in marriage to Sir Wm. Andrew, Bt., whose son, Sir Francis, sold the estate in 1698. (Morant's "Essex.")

‡ Daniel Oxenbridge. See Munk's "Roll," vol. i., p. 193.

¹ The Road to Modern Science. By H. A. Reason, B.Sc. London: G. Bell and Sons Ltd. 1935. Pp. 306. 6s.

² The Mechanism of Nature. By Prof. E. N. C. da Andrade, D.Sc. London. 1930.

JOAN OF ARC³ from a confusing mass of documents and legend. Those who have read Dr. C. McLaurin's study of Joan in "Post Mortem" will find that Mr. Milton Waldman makes her personality seem less pathological and therefore perhaps more interesting. The voices and visions, he holds, must be considered in relation to the intense religious atmosphere of the period, and he believes that "by every familiar test, medical and historical, she was a healthy and rational person." Nor does he dismiss her, as others have done, as a mere mascot with the French armies: on the contrary, her disrespect for the fatuous military conventions of the period made her intrinsically valuable. Mr. Waldman is a historian, not a writer of romances; but his vivid narrative leaves an impression of great heroism in the young girl's final struggle to win justice or mercy from the theologians of her church. "An English lord present as a spectator exclaimed after one of her answers, 'There's a fine woman; what a pity she isn't English.' It was the highest, the immemorial tribute of his race. . . ."

Waldman regards Joan of Arc as essentially a French peasant: William Cobbett considered himself a typical English one. In PETER PORCUPINE⁴ Marjorie Bowen describes the astonishing life of this ploughboy, sergeant-major, bookseller, pamphleteer, publisher, editor, historian, reformer, and agricultural innovator. Cobbett entered public life as a literary thorn in the side of the radicals: he ended it as a diehard opponent of the Industrial Revolution and the City, a champion of the People, and the collaborator with Wakley of THE LANCET in a House of Commons resolution of protest against the iniquities of the new poor-law. Miss Bowen's book shows how badly the People needed champions in the early decades of last century, and Cobbett with his tireless and ruthless invective takes his place in the history of reform. But if he was the typical Englishman it is not surprising that English honesty should sometimes be suspect. The sworn foe of every kind of public corruption and jobbery, he found nothing shocking in his own repeated bankruptcies or his failure to repay his friends. The advocate of mercy, he approved of bull-baiting; the persistent exponent of good sense, he never seemed to bother about other people's points of view. The brutal pamphleteer was also the author of "Rural Rides." Miss Bowen does her best to get consistency into the portrait, but her sympathetic intentions sometimes break down in face of the man's eternal self-satisfaction. This, and his vitality, and his amiable wife, were presumably the cause of his almost unquenchable happiness.

CALCULUS OF THE SUBMAXILLARY GLAND

THE forming of a calculus in the submaxillary gland may be quite unsuspected. Grandclaude and Driessens (*Echo méd. du Nord.*, 1935, iii., 651) divide its clinical course into three phases: the period of latency; the period of manifestation, in which the calculus produces pain or functional disorders such as acute salivary retention; and a period of complications. The glandular substance reacts to the presence of the stone by sclerosis and inflammatory change. Abscess-formation is common, but even without it chronic or subacute inflammation leading to generalised sclerosis seems to be an almost inevitable outcome. This commonly affects all parts of the gland, and so far destroys its secretory tissue as to make it functionally inactive; also it may make it so hard as to be mistakeable for a tumour or even for an osseous lesion of the jaw. Grandclaude and Driessens conclude from their histological investigations that complete extirpation of the gland is fully justified, and they think that too much care need not be taken to save it in operations for calculus. But the dense adhesions outside

the gland proper may make excision very difficult. The site of operation is always infected, and should be drained.

In the production of the calculus, Grandclaude and Driessens think that infection plays the greatest part; other suggested factors include high concentration of mineral salts in the secretion, the sinuosity of Wharton's duct, an abnormal reaction of the tissue fluids of the gland, and the presence of a true foreign body. They have found amorphous debris within the lumen of the small ducts, either forming a plug, or attached, apparently, to the wall. The plug is formed of protein material, with a nucleus of epithelial debris, of blood-cells, and of micro-organisms: from its staining reactions the substance appears to be undergoing calcification. By the side of a macroscopic calculus they have demonstrated a true microscopic stone, with calcareous granules at its core. Calcium phosphate is the main mineral deposit found in these calculi, with traces of calcium carbonate. The change in the gland, at any rate, does not seem to be localised to the site of a stone, but to be generalised. The organisms appear to gain entrance along Wharton's duct, and first to give rise to a pericanalicular inflammatory reaction.

The early and less conspicuous symptoms of calculus are slight intermittent pain, discomfort in movements involving the floor of the mouth, and slight trismus. "Salivary colic," acute salivary retention, and hernia of the salivary gland are more unmistakable signs which come later. Abscess-formation may lead to fistula into the mouth or through the skin, and Ludwig's angina may follow the extraglandular spread of the process.

ABORTION

THREE essays on abortion¹ provide an interesting demonstration of how by skilful handling the same facts may be used to plead diametrically opposite cases. Of the authors, Miss Browne is in favour of the unrestricted legalisation of abortion based on the Russian plan, Mr. Ludovici condemns abortion wholesale, while Dr. Harry Roberts steers a middle course and considers that it should be legalised in certain circumstances. It is significant that in the opinion of the first author the decision for or against abortion should ultimately rest with the woman; in that of the second, with the State; and, in that of the third, with a jury of doctors. Adjustment of the present law on abortion is probably inevitable in many countries, and those who seek the solution of the problem in the formulation of a sane compromise will find this presentation of divergent views well worth reading.

LIGHT TREATMENT FOR MASSEUSES

A BOOK designed to supply their need has been written by Dr. E. M. Anderson, who gives clearly information which is necessarily dogmatic. Granted that prolonged courses of actinotherapy are to be given by masseuses, without medical supervision of the patient at regular intervals, it may be necessary for the operator to be acquainted with the signs of the disease treated and to be able to estimate progress by reference to a text-book. But the supply of a clearly written dogmatic book on this subject for the use of masseuses² has its dangers. No one who has not had a general medical training should, except under constant medical supervision, treat cases showing definite deviation from the normal, whether of metabolic disorders, respiratory disorders, skin diseases, or even "chronic rheumatism." It is not enough to warn non-medical operators against treating tuberculosis in all its forms, for it is the undiagnosed case, the early phthisical patient, who is most likely to suffer

¹ Abortion. By F. W. Stella Browne, A. M. Ludovici, and Dr. Harry Roberts. London: George Allen and Unwin, Ltd., 1935. Pp. 143. 4s. 6d.

² The Essentials of Light Treatment, for the use of Masseuses. By Elizabeth M. Anderson, M.D., B.S. Durh., Lecturer on Ultra-violet Rays to the School of Massage, Middlesex Hospital. London: Baillière, Tindall and Cox, 1935. Pp. 81. 5s.

if he is treated thus for wasting or for anaemia. Again, the chronic lumbago case may have an unrecognised renal lesion. Dr. Anderson has failed to point out these things with sufficient emphasis in her manual for masseuses. With this important reservation the book may be recommended to those who wish to become acquainted with the elements of actino-therapy. In the procedure recommended, preliminary "test-doses" are not insisted upon, before exposures of larger surfaces for treatment. They are, however, a simple means of estimating the patients' tolerance to some of the effects of ultra-violet treatment and avoid unpleasant accidents with very small trouble to the operator.

CHAMPION OF ANIMALS

SYMPATHY is curiously related to size. Down to a point, the smaller the animal the more it excites our kindness. "Dear little squirrel," we say to our children with conscious humanity. The claims of animals below a certain bulk, however, are apt to seem negligible; few say: "dear little earwig." Similarly, when animals become too large they stray beyond the scope of our affections. Some of us even find the horse an unpredictable creature and no one sympathises much with the hippopotamus. The University of London Animal Welfare Society, however, is concerned alike with great and small, and in this year's issue of the "Animal Year Book" (vol. iii.) the claims of the musk-rat and the whale receive equal attention. Whales, indeed, were in grave danger of extermination, until the League of Nations convention for the regulation of whaling, of 1931, became international law in January of this year. The convention provides against the killing of calves and suckling whales, and requires that full use should be made of the carcasses of whales taken. These measures have come none too soon for we are told that:

"Four kinds of Right Whales, and the Pacific Grey Whale are all at vanishing point, the Sperm Whale and the Humpback are certainly found scattered sparsely throughout the oceans of the world, although they remain but a fraction of their former tens of thousands, whereas the Rorquals, after being decimated in northern waters, are now being slaughtered at the rate of thirty thousand per annum in the Antarctic."

This volume deals also with oil pollution of coastal waters which does much injury to sea-birds; with the use of electric anaesthesia (still in its experimental stages); with humane education; and with the lot of animals abroad. The account of work for the protection of animals in North Africa revolves about the almost legendary figure of Mlle. Ruperto. This lady, an Italian by birth, has, by astonishing evangelism and feats of courage, done much to improve conditions of life for donkeys, dogs, cats, and farm animals in Algiers, where she is now the secretary-general of a newly formed branch of the R.S.P.C.A. and has succeeded in making things difficult for the organisers of bull-fights.

We have commented before on the refreshing absence of sentimentality in the publications of the University of London Animal Welfare Society, and this volume comes well up to standard. The Fougasse cover of a fat man drawn by a diminutive straining donkey, as usual, touches the spot at the outset.

CONTRACEPTIVE METHODS

Two small books¹ have recently been added to the rapidly increasing number of publications on contraception. Dr. White's book is full of facts, useful to those in search of propaganda in favour of birth control, which he has collected from numerous sources and set out in a readable way. The book would have been of more value if conflicting views

and evidence had been weighed and discussed in a completely unbiased manner. Dr. White shows a tendency to suggest that birth control and sterilisation are the panaceas for most human ills.

Dr. Malleon's book is a manual on birth control methods, as used chiefly in the clinics in this country and by herself in general practice. It contains many valuable suggestions on how to deal with patients, and above all, gives the practical points on how to choose the correct cap and to teach women to use it. This is an aspect of the subject inadequately dealt with in many larger books, and for this reason as well as for its general good sense, Dr. Malleon's book is to be commended to practitioners wishing to familiarise themselves with sound contraceptive techniques and their application. In an appendix she gives a brief summary of the present position of the birth control movement in this country, and a list of voluntary clinics and of local authorities who have taken some action in the matter. She also supplies a list of reliable commercial products, pointing out (p. 64) that the list will need constant revision and that up-to-date information on sound contraceptives can always be obtained from the National Birth Control Association, 26, Eccleston-street, S.W.1.

THE CATECHISM SERIES

THOSE medical students who have been brought up from their earliest years to consult the Catechism as to their chief end (among other problems), and to memorise the official answers, may well have developed a conditioned reflex which leads them to a special appreciation of the question and answer type of book. The Catechism Series issued by Messrs. E. and S. Livingstone, of Edinburgh, at 1s. 6d. each, covers 27 subjects of the medical curriculum, alphabetically from anatomy to zoology. Many of the important subjects are divided into several parts; for example, five booklets each are allocated to medicine, pathology, and surgery, and six to anatomy. The most recent batch issued consists of histology, anatomy (Part III.), physiology (Parts III., IV., and V.). These little books are frequently revised and kept well up to date; some of them, whose subjects lend themselves fairly well to this method of revision, are in their fifth edition.

THE LIGHTER SIDE OF MEDICINE

THIS small book,¹ written in a humorous and vulgar style, will give entertainment to doctors as well as patients. Quoting Oliver Wendell Holmes, the author reminds us that "Mirth is God's Medicine," and argues that disease is apt to be regarded too solemnly by both doctor and patient. For this he holds the doctor chiefly to blame. "The invalid's day can be divided roughly . . . into two parts: (a) the period of blue funk and general wind-up prior to the meeting with the ogres; and (b) the aftermath of complete amnesia and compelling thirst that follows it . . ." the ogres, of course, being his medical advisers. He says quite sensibly, if not very originally, that it is the doctor's duty to correct mental perturbation in the patient and to remove silly fears; but is there any reason to suppose that this duty is not being constantly and fairly adequately performed? It must be remembered that the tempo of the consultation has to be set with some regard for the patient's state of mind, and the doctor must be tolerably sure that the disorder is a trivial one before he dare be light-hearted about it. Moreover, on the patient's side, the sense of humour tends to be in abeyance when pain is present, and he may find it anything but easy to obey the injunction to "smile, damn you, smile." With the author's belief in the therapeutic value of laughter and distraction there can be no disagreement, and it may be true that "an hour at the pictures may do us far more good than a week of intensive psychotherapy," though

² "The Principles of Contraception. A Handbook for General Practitioners." By Joan Malleon, M.B., B.S. London: Victor Gollancz Ltd. 1935. Pp. 157. 4s. 6d.

¹ Laugh and Grow Fit. By the Laughing Leech. Author of "Say 991" London: Frederick Muller Ltd. 1935. Pp. 133. 3s. 6d.

country practitioners of experience will not so easily be convinced that "the sting of a bee may cure the rheumatic joint." The rest of the book deals with the ordinary rules of healthy living, and contains nothing very new or striking though it is entertaining to read. The author seems to have an undue faith in the value of antiseptics, but his advice on how to examine a house, with a view to discovering whether or not it is a healthy habitation, is good and practical. There are some pleasant pen-and-ink sketches, illustrating points in the text, by Mr. Alfred E. Taylor.

INTELLIGENCE AND PSYCHOLOGICAL TESTS

Few will deny that tests of intelligence, of performance, of specific aptitudes, and, to a lesser degree, of temperament, have already justified themselves in their application to educational work. For a time their use was restricted to the diagnosis of the subnormal, but to-day it is realised that a still more important problem for the educational and the vocational adviser is, in the words of a little book recently published,¹ the "discovery of unutilized aptitudes." The manual is designed to fill a recognised gap in the training of teachers which, while it includes usually some knowledge of general psychology, seldom provides guidance for practical application of psychological methods. It may be questioned, however, whether it is desirable, even if it were possible, to equip all teachers for psychological testing.

The personal equation of the examiner has been shown recently to play a large part in the marking of examination papers, an equation which may also vary with the mood of the moment, and, however foolproof psychological tests may be made, it seems essential that their application should be in the hands of persons with specialist knowledge and experience. It is difficult in any case to see how this book could be an adequate guide to teachers, for it is singularly incomplete. It gives minute instructions regarding certain essential preliminaries—winning the confidence of the child, tact, freedom from disturbance, good lighting, ensuring that the child is at ease physically and mentally, noting signs of fatigue—but there is no description of the tests, except for one or two examples; for the actual tests, recourse is necessary to other books in which similar preliminary instructions can be found. The manual assumes an ignorance on the part of its readers which, after 20 years or more of intelligence tests, seems difficult to credit; but if any teachers still exist who are unaware of the principles on which these tests are based, they will find here an introduction to this important subject.

ROSSIUM IN NARCOTIC ADDICTION

FURTHER information is forthcoming from America as to the therapeutic value claimed for Rossium (diphenylmethyl-pyrazolonyl) to which reference was made in THE LANCET of Sept. 14th (p. 624). Its use is based upon an anaphylactic theory of morphinism propounded by Dr. Ostromislensky and by its exhibition the distress which is apt to accompany the withdrawal of morphine is said to be alleviated. Moreover it is "now being used successfully in different types of alcoholism, such as acute and chronic alcoholism, delirium tremens, and alcoholic neuritis." The accompanying administration of sugar is said to aid its operation. Dr. Ostromislensky, who introduced rossium to the notice of the profession, regards this preparation as belonging to the group of so-called neurotropic substances and points to "astonishing results obtained in sciatica and in some cases of neuritis and herpes zoster." The drug is administered orally for six

consecutive days in doses of 2 capsules every four hours, and the use of the offending narcotic—morphine, heroin, or alcohol—can, it is maintained, be safely discontinued after one or two days' treatment. Messrs. Coates & Cooper Ltd. (94, Clerkenwell-road, London, E.C.1) can supply enough of the drug for use in a few selected cases.

THE BROAD STREET PUMP

Dr. H. B. Newham, Curator of the Museum, London School of Hygiene and Tropical Medicine, Keppel-street, W.C., writes: It will be recalled that in the cholera epidemic which was prevalent in London in 1854 the water from the pump in Broad-street, Golden-square, Soho, played a dramatic part in the dissemination of the disease. For museum purposes at this institution I am anxious to find a print or engraving showing this pump and its immediate surroundings, and I should be glad if any of your readers could give me information as to where such an illustration, if existent, could be found.

A PRESCRIBER'S LIST.—Messrs. Roberts and Co. (76, New Bond-street, London, W. 1) have brought out a fifth edition of this useful handbook to proprietary drugs of home and continental manufacture. In eight columns are given the name of the preparation, its maker, composition, form, size, price, indications, and dose. The list is more comprehensive than the previous editions, acknowledgment being made to 47 manufacturers and agents for their assistance in its compilation. A copy will be sent on request free of charge to any member of the medical profession.

Appointments

EDWARDS, COLIN, M.B. Sydney, D.P.M., has been appointed Registrar to the Out-patient Department of the West End Hospital for Nervous Diseases, London.
GHEE, P. H. R., M.B. Camb., F.R.C.S. Eng., Resident Surgical Officer to the Prince of Wales's Hospital, Plymouth.
McLAUGHLIN, F. L., M.D. Irel., D.P.M., Hon. Clinical Psychologist to the Out-patient Department of the West End Hospital for Nervous Diseases, London.
MORRIS, Miss E., M.B. Lond., Resident Anaesthetic Registrar at the Hospital for Sick Children, Great Ormond-street, W.C.
RIDLEY, H., M.B. Camb., F.R.C.S. Eng., Hon. Consulting Ophthalmic Surgeon to the Royal Buckinghamshire Hospital, Aylesbury.
London County Council Hospital Staff.—The following appointments, promotions, and transfers are announced: A.M.O. (I.) and (II.) = Assistant Medical Officer, Grades I. and II. (T.) = temporary:—
HOWARD, R. N., M.D. Melb., F.R.C.S. Eng., M.C.O.G., A.M.O. (I.), St. James;
MORTON, T., M.D., M.R.C.P., A.M.O. (I.), Lewisham;
LIPSCOMB, J. F., M.B. Sydney, A.M.O. (I.), Downs Hospital for Children;
BENHAM, L. R., M.B. Melb., A.M.O. (I.), White Oak;
LLOYD, E. T., M.R.C.S. Eng., D.P.H., A.M.O. (I.), South Western;
LILLIS, W. J., L.R.C.P. Lond., A.M.O. (I.), Brook;
PAGET, M. Y., M.R.C.S. Eng., House Surgeon, St. Mary Abbots;
VALENTINE, W. H., B.A. Camb., M.R.C.S. Eng., House Physician, St. Mary Abbots;
DAX, E. C., B.Sc. Lond., L.M.S.S.A., House Physician, Lewisham;
BRADLEY, D. J., M.B. Dub., House Physician, St. Andrew's;
ROBERTS, B., M.R.C.S. Eng., House Physician, St. Andrew's;
KEITH, A. M., M.B., House Surgeon, Hackney;
THISTLETHWAITE, E. C., M.B., Visiting M.O. (T.), St. Margaret's;
BATSON, R. E., M.B. Edin., District M.O. (T.), Area III., District C (Finsbury);
WATSON, T. T. B., M.B. Camb., District M.O. (T.), Area VI., District B (Kensington);
WILLIAMS, H. V., M.R.C.S. Eng., District M.O. (T.), Area IV., District A (2) (Hampstead);
McCLURE, C. R., M.R.C.S. Eng., District M.O. (T.), Area IV., District B (Marylebone);
FIELD, A. B., M.B. Camb., Senior A.M.O. (II.), St. Mary, Islington;
TAYLOR, I., M.B., D.P.H., Senior A.M.O. (II.), North Eastern;

ADDRESSES AND ORIGINAL ARTICLES

UNDULANT FEVER

WITH SPECIAL REFERENCE TO ITS CLINICAL ASPECTS
IN ENGLAND AND WALES *BY SIR WELDON DALRYMPLE-CHAMPNEYS, Bt.,
M.D. Oxon., F.R.C.P. Lond.

A MEDICAL OFFICER OF THE MINISTRY OF HEALTH

THOUGH it is my intention to concentrate chiefly upon the clinical aspects of undulant fever, I should like first to say a few words about its origin and the way in which it is transmitted.

HISTORY AND EPIDEMIOLOGY

Everyone has heard of the ravages caused by "Malta fever" in the Mediterranean last century (and probably long before); how Marston rescued it from the rubbish-heap of the continued fevers and Hughes described it in his classical monograph; how Bruce discovered the causative organism which he called the *Micrococcus melitensis*; and how through the brilliant work of the Royal Society's Commission—and especially that of Zammit (whom we mourn to-day), Horrocks, and Shaw—the source of infection in the Mediterranean was shown to be the milk of infected goats. These discoveries were followed with admirable and, one must confess, exceptional promptitude by the famous order forbidding the consumption of unboiled goat's milk by the forces of the Crown in the Mediterranean, one of the most successful and dramatic practical applications of scientific knowledge in the history of preventive medicine. There, however, the matter rested for some years, and if it had not been for the acute observation of Miss Alice Evans in the United States undulant fever would have been of little interest to medical men practising in this country. To Miss Evans is due the credit of recognising the very close relationship between Bruce's *Micrococcus melitensis* (now known as the *Brucella melitensis*) and Bang's *Bacillus abortus* (now known as the *Brucella abortus*) which he had shown to be the cause of contagious abortion in cattle. Her discovery was followed quickly by the recognition, in America, Rhodesia, and subsequently in every continent and in nearly every country of the world, of numerous cases of a hitherto unrecognised but certainly not new disease which was indistinguishable from the "Malta fever" of the Mediterranean but was shown to be conveyed not by goat's milk but by the milk, carcasses, and excreta of bovines, and less frequently of swine.

With regard to the origin of the cases recognised with increasing frequency in this country I will only remark that all the evidence I have collected during the last seven years points to the consumption of cow's milk as the commonest mode of infection, though I will freely admit that in a number of cases the aetiology remains at present extremely obscure. Contagious abortion of cattle is very widespread in this country (probably well over half our herds are infected, pedigree and tuberculin-tested herds being as often infected as others); and where efficiently pasteurised milk is consumed, as in London, undulant fever is almost unknown. The moral is obvious.

After these preliminary remarks I will pass to the clinical aspects of this disease.

AGE- AND SEX-INCIDENCE

Of the 253 patients in my series whose sex was known 170 were males and only 83 females (Fig. 1). This great preponderance of males over females has

been observed in nearly every country in which the disease has been studied, but its explanation is obscure, as is also that of the low incidence of the disease in childhood. Of 250 patients of known age in my series only 9 were under ten years of age and only 3 under five years. The age-group 10-20 contained 28 cases and the group 20-30 contained 29 cases, but 107 patients (i.e., 43 per cent.) were between thirty and forty.

FIG. 1.—Sex and age of 250 patients.

CLINICAL COURSE

The onset of definite fever is usually preceded by a period of tiredness, malaise, headache, and sometimes sweats and cold feelings, varying in duration from a day or two to several weeks or even months. It is uncertain whether this period should be regarded as the prodromal stage of the disease or as a period of ill-health due to some other cause which opens the door to infection by the *Br. abortus*. In any case it is followed by the onset, often sudden, of definite symptoms, and the temperature, which one may suspect of having been abnormally high during the preceding period, is now found to be definitely supranormal. A remarkable feature of this disease is the conspicuous disproportion in many cases between the height of the temperature and the degree of prostration of the patients, who are often found to be pursuing their usual avocations (sometimes hard manual labour) with temperatures of 103°-105° F., and after many weeks of high fever, such as would produce profound prostration in such a disease as enteric fever, are comparatively fit and may make a rapid recovery.

The symptomatology of the disease is extremely variable, making diagnosis on purely clinical grounds often very difficult; but the commonest symptoms

* Read before the Nottingham Medico-Chirurgical Society on Nov. 6th.
5861

accompanying the onset of definite fever in my series were, in order of frequency, sweating (which is often profuse and sometimes sour-smelling), malaise and fatigue, headache, anorexia, pain in the back or limbs, and constipation. Other common signs and symptoms are rigors, enlargement of the spleen, cough, sore-throat, abdominal tenderness and/or pain, depression, diarrhoea, insomnia, rashes of various kinds, arthralgia and arthritis, epistaxis, nausea, and vomiting. The relative frequency of the commonest signs and symptoms is shown in Fig. 2. The temperature charts show great variations, but they usually display the daily swing which one associates with septicemias, and in most cases at some stage in the course of the disease may be seen the characteristic waves which suggested to Hughes the name by which the disease is now commonly known. These waves, as will be seen from Fig. 3, are formed by the summits of the small diurnal waves which are usually reached in the late afternoon or during the night. On analysing 66 temperature charts of cases in my series I find definite undulations in 37 cases, though this type of temperature curve is hardly ever present throughout the course of the disease.

Four cases showed a definitely remittent type of temperature over an appreciable period, but, as will be seen from Fig. 4, the remittent chart is usually merely an undulant chart in which the daily minimum is subnormal.

Occasionally the temperature is irregular throughout the course of the disease, as in the chart reproduced in Fig. 5; that is to say, no definite undulations occur and the evening rise and morning fall are irregular in their appearance, the rhythm being sometimes reversed for a day or two but seldom for longer. The temperature chart in 13 cases in my series was irregular throughout. The pulse is generally slow in proportion to the temperature. Afebrile periods, which commonly extend over a few days but are occasionally much longer, often interrupt the course of the fever and raise hopes in the patient and his medical adviser which are doomed to disappointment. The disease may terminate by crisis or lysis. The rapid return of the temperature to normal followed by recovery will often tempt the doctor to ascribe this happy result to the particular treatment which immediately preceded this occurrence; but all experienced observers are agreed that

such a sudden termination is common in untreated cases and should therefore be interpreted with great caution. The average duration of the fever in my series was about 11.5 weeks, but varied from a minimum of 1 to a maximum of 104 weeks (excluding one exceptional case of many years' duration). There does not appear to be any close correlation

FIG. 3.—Temperature chart showing characteristic "undulant" fever.

between the severity of the disease in any particular case and its duration. Cases in which afebrile and sometimes symptom-free intervals of several months or years were followed by recurrence of the typical disease without any evidence of reinfection present a difficult problem, but various considerations suggest that the *Br. abortus* may lie dormant (e.g., in the spleen or lymph glands) for long periods.

COMPLICATIONS AND SEQUELÆ

A considerable variety of complications occurred in my series including arthritis (occasionally with temporary effusion into the joints), bronchitis and broncho-pneumonia, ulceration of the mouth or throat, orchitis, swelling of the legs, cystitis, myocarditis, pericarditis, phlebitis, thrombosis, uræmia, deafness, visual disturbances, meningismus, amnesia, and suicidal tendencies. True sequelæ were not common, persistent weakness and neuralgia being those most commonly met with.

DIAGNOSIS

Clinical.—The diagnosis on clinical grounds of a disease with such a varied symptomatology as undulant fever naturally presents considerable

difficulty, but a provisional diagnosis is often possible if the commonest symptoms which I have just described are borne in mind, and on many occasions the reputation of the practitioner has been greatly enhanced and the patient saved much unpleasant and ineffective treatment by the doctor's knowledge of this disease. In spite of the apparently low incidence of the disease (which I believe to be more apparent than real) it is wrong to regard a diagnosis of undulant fever as a last desperate resort when every other cause of fever has been excluded.

FIG. 2.—Commonest signs and symptoms in 300 cases of undulant fever.

Seeing that the agglutination test, properly carried out, will give a definite answer in nearly all cases after the fifth day of fever, blood specimens should be sent for this test at once in all cases in which the clinical picture creates a suspicion of undulant fever; and when blood is sent for the Widal test for organisms of the enteric group

agglutinin titre has persisted for several years after an attack of undulant fever (e.g., a titre of 1 in 640 after 4½ years), but the fall in titre is usually fairly rapid and cases (of which there are several in my series) in which typical relapses have occurred after months of complete freedom from symptoms suggest that the persistence of agglutinins in a high concentration may perhaps indicate a lurking infection.

Finally, it should be noted that occasionally cases are encountered in which the agglutination test proves negative though the clinical picture and history strongly suggest the diagnosis of undulant fever, and at least one instance is on record in which a *Br. abortus* grown from the patient's blood was not agglutinated by the patient's own blood-serum. In such cases two confirmatory diagnostic tests are still available—viz., culture of the organism from the blood, faeces, urine, &c., and the intradermal test.

The intradermal test, which closely resembles the Schick test for diphtheria immunity, is carried out with a killed suspension of *Br. abortus*, a fat-free antigen, or a filtrate of a broth culture of the organism, the filtrate being known as "abortin" or "brucellin." About 0.1 to 0.2 c.cm. of one of these preparations is injected into the skin on the flexor aspect of the forearm and an equal quantity of a control (e.g., sterile broth) nearby. The usual area of redness and swelling is produced within 24 hours by the specific antigen in a patient sensitised by infection with a brucella. This test does not appear to possess a

FIG. 4.—"Remittent" type of fever. Daily minimum subnormal.

the pathologist should always be asked to put it up against a brucella suspension as well. Many obscure cases are being elucidated by this means, and many more, I feel sure, are passing unrecognised from neglect of this maxim.

A positive agglutination test is, as I have already remarked, given in nearly all cases of undulant fever after the fifth day. Great difference of opinion has existed as to the titre which should be regarded as diagnostic, but it seems probable from the work of Wilson and Miles that non-specific agglutinations have been due in most cases to the use of unsatisfactory brucella suspensions (i.e., those made from rough or partly rough strains) and that with satisfactory methods even very low titres may be regarded as diagnostic of present or past infection. Fortunately, however, the titre in most cases is so high as to place the matter beyond doubt, the average titre for 255 cases in my series being just under 1 in 1500; in only one case (with a very characteristic clinical picture) was it less than 1 in 100. At the same time it is important to recognise the limitations of the agglutination test in the diagnosis of this disease. Pro-zones and para-zones (see Table) are of common

—	1 in 25	1 in 50	1 in 125	1 in 250	1 in 3000
Pro-zone ..	—	—	Trace	+	+

—	1 in 25	1 in 50	1 in 125	1 in 500	Up to 1 in 2500	1 in 500
Para-zone ..	+	+	—	—	+	—

occurrence (they were recorded in 10.7 per cent. of my cases) so that if the test is not taken over a large range of dilutions agglutination may be missed. Further, though agglutinins usually appear early their appearance is occasionally delayed, so that a single negative test is not really sufficient to exclude undulant fever and the test should be repeated if possible. Such repetition is also useful in cases in which a low titre raises a doubt as to whether a present or past infection is indicated, as a rising titre indicates an active infection, and in the later stages can be regarded as a good prognostic sign. Many cases are on record in which a comparatively high

FIG. 5.—Irregular fever.

diagnostic value equal to that of the agglutination test, but it gives positive results in some cases in which the latter test is negative or so weak as to be doubtful. The intradermal test was carried out in only 6 cases in my series, and the intensity of the reaction was sometimes in marked contrast to the height of the agglutinin titre, one case with an agglutinin titre of 1 in 125 giving a strongly positive intradermal test, whilst another case with a titre of 1 in 1280 was only weakly positive. The intradermal test can therefore be regarded as a useful adjunct to diagnosis.

Blood culture is often successful in this disease, and if positive it not only clinches the diagnosis but provides the material for an autogenous vaccine should this be required. The blood should be taken at the time of day when the fever is highest and should be kept at body temperature until the culture medium is inoculated. After defibrination 5 c.cm. quantities of the serum should be sown in at least two flasks containing 100 c.cm. or more of liver infusion broth, both of these flasks being then incubated at 37°C., one of them aerobically and the other in an atmosphere containing 10 per cent. carbon dioxide. The cultures so made should be plated out on liver infusion agar every five days, incubating in two ways as before.

As the brucella group grow very slowly the flasks should be kept for at least five weeks or until positive subcultures have been obtained. In my series blood culture was successful in 10 out of 77 cases (13 per cent.) in which it was tried.

The organism may also be grown from the urine, as in 4 out of 47 cases in my series, but culture from the faeces was unsuccessful in 21 cases and the same was true for a throat-swab and two specimens of cerebro-spinal fluid. *Br. abortus* was grown from the spleen of one case post mortem and culture from the liver and mesenteric glands should also be attempted in a fatal case.

Though the blood count in undulant fever is not sufficiently characteristic to justify a diagnosis on this ground alone, it may yet afford useful confirmatory evidence. The two commonest features in this disease are anaemia and an absolute or relative lymphocytosis. In one-third of my cases there were less than $4\frac{1}{2}$ million red cells per c.mm., and in 13 per cent. there were less than $3\frac{1}{2}$ millions. As regards the white cells in 66 per cent. of the cases in which a differential white count was carried out more than 40 per cent. of the cells were lymphocytes and in 45 per cent. they constituted more than 50 per cent. of those counted.

DIFFERENTIAL DIAGNOSIS

In my series of cases 35 diagnoses other than that of undulant fever were made but some of these were far commoner than others. An alternative diagnosis was made in 91 cases, enteric fever being diagnosed in 41, influenza in 24, paratyphoid in 12, pulmonary tuberculosis in 6, malaria in 4, and cholecystitis in 3. Seven other diagnoses were made in 2 cases each, and the remaining diagnoses in 1 case each. Multiple diagnoses were made in 18 cases, and in one case 7 different diagnoses (viz., influenza, paratyphoid fever, tuberculosis, intestinal toxæmia, thyrotoxiæmia, glandular fever, and subacute bacterial endocarditis) were made before undulant fever was suspected. In the latter case the physician was misled by a positive agglutinin titre of 1 in 150 for *Bacillus paratyphosus* B in a test carried out early in the disease, but if it had been the practice at the laboratory concerned to put up all "Widal bloods" against *Br. abortus* as a routine the correct diagnosis might have been made four months earlier.

A full discussion of the differential diagnosis in undulant fever would be inappropriate here, but I may mention that the disease may be differentiated from typhoid fever (apart from laboratory tests) by the sweating which is commoner and usually much more profuse in undulant fever, the prostration which in typhoid fever is roughly proportionate to the severity and duration of the disease but in undulant fever is much less than would be expected, and by the far greater frequency of diarrhoea in enteric fever than in undulant fever (34.4 per cent. of the typhoid patients in Osler's series had diarrhoea and only 11 per cent. of the undulant fever patients in my series). The temperature chart will also help in this differentiation, especially if this shows distinct undulations and the fever lasts more than forty days.

PROGNOSIS

The mortality in this disease is very low, death having occurred only 9 times in 290 cases of my series (3.1 per cent.). I have already mentioned the long duration of the disease in many cases as well as the infrequency of sequelæ. The most favourable

indications of approaching recovery are the disappearance of hitherto persistent symptoms (e.g., sweating, headache, anorexia), clearing of the tongue, rise in the agglutinin titre and an apyrexial period of more than five days or, in a long case with intermittances, of greater duration than has previously occurred. High fever, unless very prolonged, is not necessarily a very serious sign even when accompanied by rigors, but general toxæmia and persistent or severe hæmorrhages (especially from the bowel) are of grave import. Complicating conditions such as renal or cardiac disease or broncho-pneumonia naturally reduce very seriously the patient's chances of recovery, and the prognosis is worse with increasing age, though a patient aged 80 in my series, who was unconscious and incontinent for two weeks, made a rapid and complete recovery after 23 weeks of fever.

TREATMENT

General.—In a disease such as undulant fever in which the fever is usually prolonged, and in which weakness, anorexia, and depression are often severe, it is important to maintain the patient's strength and to tempt his appetite. For this reason he should be encouraged to eat whatever he fancies and can digest, and "slops" should be restricted to those periods when the fever is very high or the digestion disturbed. For the same reason alcohol should not be excluded merely because the temperature is above normal. Constipation, a common symptom, should receive careful attention, as flatulence, anorexia, and headache can often be reduced or eliminated by keeping the bowels open. The bed-clothes and bedclothes should be changed whenever wetted by the sweats, which are often frequent and very profuse. Owing to the frequency of heavy furring of the tongue and a nasty taste in the mouth attention to oral hygiene will often make a big difference to the patient's comfort and appetite. The alternation of waves of fever with apyrexial periods makes the question of when the patient should be allowed out of bed a difficult one. In my experience there has been no obvious correlation between getting up and the occurrence of relapses, though the latter may be more severe if the patient gets chilled or over-tired by this means. The possibility of broncho-pneumonia and the aggravation of any cardiac condition present should also be borne in mind. A good general rule, which has proved useful in my experience, is to allow at least five days of apyrexia before getting the patient out of bed, and to be cautious with regard to exertion and going out of doors for another week.

Drugs.—Antipyretics should be used very sparingly as they have no permanent effect upon the temperature and increase the sweating, weakness, and depression. Aspirin or amidopyrin (if the patient has no idiosyncrasy to this drug creating a danger of agranulocytosis) may be used in small doses for headache or other pain or for insomnia. Salol and carminatives are useful for the relief of flatulence, and the former may have some lethal action on the causative organism.

Vaccines, both autogenous and stock, have been employed largely in this disease but appear to be very uncertain in their effect. Thus out of 21 cases in my series treated with stock brucella vaccines only 4 were definitely benefited, whilst only one of 6 cases given autogenous vaccines showed improvement. Curiously enough non-specific vaccine therapy (i.e., protein shock) was more successful than specific vaccine therapy in my series, 9 out of 13 cases given

injections of typhoid-paratyphoid vaccine (dosage 25 to 75 millions at intervals of 3 to 6 or more days) being definitely benefited thereby. Vaccine therapy is, however, definitely contra-indicated in old age or infancy and in debilitated patients or those with cardiac or renal complications.

Edwenil (1 to 4 c.cm. subcutaneously every 4 hours) is a harmless remedy which produced definite improvement in 3 cases of my series, and it seems probable that other patients might also have benefited if the dosage had been pushed. S.U.P. 36 seems also to have helped in a few cases (4 out of 12).

Many other remedies such as Mercurochrome, Argochrome, Trypaflavine, Bayer 205, Solganal, neoarsphenamine, Stabilaran, nuclei acid, colloidal solutions of silver, manganese, and sulphur, and injections of whole blood and of milk have been used, but the results appear to have been disappointing, and the intravenous antiseptics are by no means free from risk.

Finally, reference should be made to brucellin or abortin, the substance employed for the intradermal diagnostic test. This usually consists of the filtrate of a three weeks' broth culture of the causative organism. Considerable success has been claimed abroad for treatment with this substance, usually by intramuscular injection after a preliminary skin dose, but I have no details of the results of such treatment in this country though I have done my best, with the coöperation of Prof. G. S. Wilson, to encourage its trial.

INTRANATAL AND NEONATAL DEATH

A REVIEW OF NINETY-NINE CONSECUTIVE CASES

By J. M. SMELLIE, M.D. Edin., F.R.C.P. Lond.

PHYSICIAN, GENERAL AND CHILDREN'S HOSPITALS,
BIRMINGHAM

This paper is based on the clinical and post-mortem records of a series of infants whose deaths had been reported to H.M. coroner for the city of Birmingham. All of them had died suddenly or unexpectedly within the intranatal or neonatal periods. The causes of death as ascertained by autopsy were as follows:—

	Cases.
Stillborn	21
Asphyxia neonatorum	31
Intracranial hemorrhage	17
Broncho-pneumonia	11
Congenital defects—	
Congenital heart disease	3
Cleft palate	1
Scurvy	1
Sepsis	1
Intraperitoneal hemorrhage	1
Shock and asphyxia	1
Suffocation	3
	99

STILLBIRTHS

Stillbirths are reported to the coroner when no doctor or midwife is present at the birth, or when there is any suspicion of foul play. In several of my cases birth was premature, but all the infants were viable as judged by their length, weight, and general development. Many had tears of the dural septa but these were all incomplete and the hemorrhages that had resulted were insignificant and insufficient to have caused fatal issue.

Failure of survival, therefore, must be considered as due to the non-establishment of normal respiration.

One cannot go so far as to say that all would have lived if modern methods of treatment had been available immediately, but there is no doubt that in a very large proportion death could have been avoided. In none was any condition found that was incompatible with life. In other words, the problem is similar in all respects to that encountered in dealing with neonatal asphyxia to which I refer next.

ASPHYXIA NEONATORUM

This group contains 37 of my cases. Of these, 23 died within twenty-four hours of birth and 14 lived for more than a day. Of the latter 10 died within forty-eight hours of birth but 3 lived for more than two days, and 1 for four days. In a considerable number a midwife was in attendance at the time of the birth, no difficulty was experienced in getting respiration established, and the infants were stated to have cried well. On the other hand, a certain number of the mothers had concealed their pregnancy and were alone when the baby was born; and when help arrived the infant was dead.

There is nothing of importance in the obstetric histories of any of those cases in which reliable information could be obtained; all except one were vertex deliveries and in none was instrumental aid necessary.

In all the infants the lungs were very imperfectly expanded; in fact in none did they fill more than half their respective pleural sacs. The other pathological changes encountered were those commonly found in death from asphyxia from any cause and do not require reiteration here, with the exception of the increased intracranial pressure to which reference will be made presently.

Before the problem of asphyxia neonatorum can be solved the mechanism whereby normal respiration is established in the newly born baby has to be elucidated. A vast literature is growing up round this subject which it is impossible for me to summarise fairly here, for much is controversial and much speculative. The observations that have recently been published by Barcroft¹ are, however, illuminating. He discusses three possible causes for the first breath, viz.: (1) oxygen-want, (2) excess of carbon dioxide, and (3) increased blood pressure in the brain. His original investigations have enabled him to produce positive evidence that lack of oxygen may lead to respiration, whereas no such evidence was forthcoming concerning the two other suggested causes. At the same time, Barcroft qualifies this opinion by stating that whilst oxygen-want is the essential cause of the first breath the amount of carbonic acid in the blood cannot be ignored. Confirmation of this work will be awaited with interest, as it may go a long way towards the solution of asphyxia in the new-born infant.

Asphyxia neonatorum is commonly divided into two groups—asphyxia livida and asphyxia pallida. The former is regarded as a condition akin to suffocation and the latter to surgical shock. Moncrieff² does not subscribe to this classification but maintains that the colour of the baby is no clear guide to the degree of respiratory failure. He does agree that the pallid infants present a more serious problem, and as regards causation states that almost any of the aetiological factors may result in either cyanosed or pale babies. In the cases here considered all the infants died from blue asphyxia, and many were reported to the coroner because of suspicion that death was due to suffocation.

Cruikshank³ in his monograph on neonatal death draws attention to the fact that oedema of

the brain and meninges is present in almost all cases of asphyxia neonatorum, and my experience fully confirms this. What part the increased intracranial pressure thus produced plays in the production or aggravation of the asphyxia is difficult to decide. It is obvious that the respiratory centres must be embarrassed by such pressure, but it is equally important to bear in mind that asphyxia will produce cerebral congestion and oedema. Which is cause and which effect is the problem. I have separated my cases of frank intracranial hæmorrhage from those of asphyxia neonatorum, and my opinion is that the cerebral oedema found in asphyxia is in the main the result of the asphyxia and not the cause. At the same time it cannot be controverted that the more severe the asphyxia the greater the cerebral oedema, and the greater the cerebral oedema the greater will be the embarrassment of the respiratory centres.

The correct methods of treatment of the asphyxiated newly born infant are now founded on sound knowledge, but the old-fashioned and useless methods die hard. These infants are suffering profoundly from shock; therefore great care in handling and the provision of warmth are of paramount importance. Next comes "the toilet of the air-way,"⁴ and thirdly inhalation therapy.^{2, 4, 5} It is not my intention to enter into the details of these methods of resuscitation but I will content myself with drawing attention to three important points in connexion with inhalation therapy. Firstly, carbon dioxide is the normal stimulant to the respiratory centres, but in excessive amount it is a respiratory depressant. Secondly, carbon dioxide can only be produced in the tissues from oxygen. And, thirdly, a cylinder of oxygen is of much greater value than a cylinder of carbon dioxide; the former can do nothing but good, whereas the inspiration of pure carbon dioxide, except for a very brief period, will prove fatal.

Lastly, the association between asphyxia and increased intracranial pressure, to which attention has already been directed, has to be considered. In this connexion treatment by means of hypertonic rectal saline as advocated by Moncrieff⁶ undoubtedly constitutes a real therapeutic advance. He advises the introduction of 2-3 oz. of 10 per cent. saline into the rectum of the new-born babe, as soon as any symptoms appear. This should be done slowly, with the baby in the cot and with the minimum of disturbance, and the buttocks should be held together to get as long a retention as possible.

NEONATAL INTRACRANIAL HÆMORRHAGE

I have included in this division only those of my cases with gross intracranial hæmorrhage. In all free blood or blood-clot was present over the surface of the cerebral hemispheres in part or in whole. In some, in addition, hæmorrhage had occurred beneath the tentorium cerebelli but none showed subtentorial hæmorrhage only. Demonstrable tearing of the tentorium was present in 12 instances—in 6 of which the tears were complete—and in a few the falx was also damaged. In one case the source of the hæmorrhage was a tear of the superior longitudinal sinus. Of the 12 in which the hæmorrhage was associated with partial or complete tentorial tears 10 had been born precipitately, 1 was an instrumental delivery due to protracted labour, and the twelfth was a normal labour.

Only 3 of these 17 infants survived for more than twenty-four hours, and most of them died very shortly after birth. One lived for forty-two hours,

this being an infant of 6½ lb. who was born with a normal labour, breathed well, and at autopsy had much free blood over the surface of both cerebral hemispheres.

It is now generally agreed that trauma plays the significant part in the production of neonatal intracranial hæmorrhage. This subject has been studied exhaustively by Holland,⁷ who has shown that when the fetal head undergoes changes in shape alterations in the tension of the dural septa are inevitable, owing to the nature of their attachments to the cranial bones. Most of Holland's cases were the result of breech presentation and forceps delivery through a contracted pelvis, but a few resulted from apparently normal labour and only one was precipitate labour. Capon⁸ gives as the determining causes of hæmorrhage excessive head-moulding, too rapid head-moulding, and fetal asphyxia. Of my 17 cases, the labour was precipitate in 9 and protracted with instrumental delivery in 2; one was a breech presentation, and in the remaining one the labour was stated to be normal or at all events more or less uneventful. These figures thus indicate that too rapid head-moulding is a potent factor in the production of neonatal and intracranial hæmorrhage. Hence the danger of precipitate birth.

Ford⁹ maintains that prematurity is an important contributing cause, and my figures support this contention in that over half were under 6 lb. in weight.

Little of importance emerges from a study of the clinical histories of these infants. As most died very shortly after birth, and as almost none were born or treated in any institution, or indeed had been examined by a medical man, no facts of significance can be elicited. In no case was the diagnosis suspected during life, and even if it had been it is difficult to believe that any form of therapy could have saved life, such was the extent of the hæmorrhage.

In my experience with coroners' post-mortems fatal neonatal intracranial hæmorrhage is more likely to follow precipitate labour and too rapid head-moulding than prolonged, difficult, and instrumental deliveries. The obstetricians have, in my opinion, been unjustly blamed in the past for many of these catastrophes.

BRONCHO-PNEUMONIA

If the lungs of all the infants in this series had been examined microscopically there is no doubt that consolidation would have been found in many, for atelectasis and neonatal broncho-pneumonia are closely allied pathological conditions. However, I am here concerned only with those in which the consolidation was so extensive as to be evident to the naked eye, and therefore the primary cause of death. There are 11 of these, of whom the youngest was nine hours, the eldest twenty-eight days, and the average eighteen days old. In 6 the history was to the effect that the infants had appeared to be thriving satisfactorily and had been free from cough or other symptoms of respiratory disorder. Their deaths were unexpected, and in several the information received pointed to death from suffocation.

CONGENITAL DEFECTS

A congenital defect was the cause of death in only 4 of my cases. In several others congenital abnormalities of one kind or another were an accidental post-mortem finding—e.g., solitary kidney—but in none had they contributed to the fatal issue.

All three dying from *congenital heart disease* had some degree of aortic stenosis. The baby with the cleft palate was 8½ lb. at birth: various methods of feeding were tried without success, and he really died from marasmus, for at the time of death the weight had dropped to 5½ lb.

SUPRARENAL HÆMORRHAGE

Suprarenal apoplexy is a fascinating and baffling condition, the ætiology of which appears to be wrapped in obscurity. Arnold¹⁰ states that the causal factors mentioned in the literature include asphyxia, trauma, eclampsia in the mother, purpura and fever in the mother, thrombosis of the suprarenal veins, syphilis, hæmophilia, and toxic factors such as burns and diphtheria. In both my cases the infant died shortly after birth, and in both massive hæmorrhage had occurred into one suprarenal gland. They were fully mature, and there is nothing in the histories of either mothers or babies to suggest possible causes.

INTESTINAL VOLVULUS

This was a mature infant that suddenly collapsed on the third day and died without warning. Post-mortem examination revealed a general peritonitis with faecal material in the peritoneal cavity. Intestinal obstruction had been caused by a volvulus of the cæcal variety and the cæcum itself had perforated.

SEPTICÆMIA

This infant had panophthalmitis. It had lived for thirteen days and had received only some sporadic treatment for ophthalmia during the first few days of life. Death was due to septicæmia.

DEATH DUE TO VIOLENCE

One infant died from *intraperitoneal hæmorrhage* due to a rupture of the liver.

This was the second child of a single woman who had concealed her pregnancy. The baby was born after she had been in labour for some hours and while she was standing upright over a blanket. At autopsy the body was that of a fully mature infant weighing 7 lb. 10 oz. with cord and placenta still attached. On opening the abdomen the peritoneal cavity was seen to be filled with blood due to a rupture of the liver just where the umbilical vein entered. The pull on the umbilical cord just as the baby hit the floor must have produced sufficient tension to cause this rupture of the liver but insufficient to damage the cord externally.

The death from *shock and asphyxia* took place in circumstances which are instructive and probably unique.

A healthy male infant, eighteen days old, was being washed by his mother on her knee and over a bowl of water on the floor when the woman fainted. When she came round she was lying on the floor and the baby's head was in the bowl of water and its feet sticking out. At the post-mortem examination the body was that of a well-nourished infant weighing 7 lb. 12 oz. There was no external bruising of the head or elsewhere. The child was not drowned, and my explanation of this catastrophe is that it was concussed by a blow on the head from hitting the bowl in its fall; and this, combined with the sudden immersion in the water, produced death from shock and asphyxia.

Only three of my cases died from *suffocation*. In view of the fact that in a considerable number of the total cases under review both the circumstances and the external examination of the bodies suggested that death might have been due to suffocation, the very small number in which this was actually proved

to have been the cause is arresting. In particular, the external appearances of a baby that has died from pneumonia and one that has been suffocated are usually identical, and in fact differential diagnosis, in spite of the fullest history of all the circumstances, can only be established by post-mortem examination. In Birmingham all these cases are subjected to a detailed autopsy, and my experience leads me to fear that where this practice is not carried out there is a very real danger that mothers may be admonished for causing the deaths of their babies when they are innocent. In consequence I feel that I cannot urge too strongly the universal adoption of the Birmingham policy. It is only by post-mortem examination that the cause of death can be irrefutably ascertained, and by such procedure the risk of stigmatising the parents when such would be unwarranted and unjust will be entirely avoided.

SUMMARY

The clinical and post-mortem findings in 99 cases of death in the intranatal and neonatal period that were reported to the Birmingham coroner have been here reviewed. Of these, 75 failed to survive because of factors directly attributable to birth (accidents associated with labour or inability to establish normal respiration); 15 died from disease not directly associated with birth factors; 4 died from congenital abnormalities; and 5 met their death from violence.

It is appreciated that these constitute a highly selected group and form but a very insignificant proportion of the total stillbirths and neonatal deaths in the city of Birmingham. Furthermore, this series is not complete in itself in that it does not include all the cases in this age-period that were reported to the coroner. Nevertheless, they do constitute a valuable collection for at least two reasons: the causes of death are based on personally performed post-mortem examination, and they occurred amongst a section of the population outside institutional guidance or control and with a minimum of medical supervision; in fact, in the very large majority no medical man had been in attendance. No useful purpose, therefore, could be served by attempting to compare my series with those recorded by other observers, most of which have been obtained from institutional practice. Whilst hospitals must of necessity deal very largely with the abnormal and difficult case, on the other hand modern methods of diagnosis and treatment of the newly born child are always available immediately. In view of these circumstances my cases can best be regarded as a complement to those recorded by others. It is hoped that they will help to shed light from this unaccustomed angle on the extremely important and complex subject of stillbirth and neonatal death.

I have to thank Dr. W. H. Davison, H.M. coroner for the city of Birmingham, for permission to make use of the clinical and post-mortem records of these cases.

A STUDY OF HÆMOLYTIC STREPTOCOCCAL FIBRINOLYSIS

IN CHRONIC ARTHRITIS, RHEUMATIC FEVER, AND SCARLET FEVER

By C. H. STUART-HARRIS, M.D., M.R.C.P. Lond.

(From the Department of Medicine, British Post-graduate Medical School, London)

IN contrast to the negative results of cultural methods in the study of the ætiology of chronic arthritis and rheumatic fever, indirect immunological methods of investigation have suggested that the hæmolytic streptococcus plays a part in the causation of these diseases. Thus Todd (1932), Myers and Keefer (1934), Griffiths (1934), and Coburn and Pauli (1935) have shown that in patients in whom hæmolytic streptococci can be isolated from the foci of infection, antibody which neutralises streptococcal hæmolysin can be detected in the blood while similar high titres of antihæmolysin are encountered in cases of rheumatoid arthritis and rheumatic fever. The phenomenon of hæmolytic streptococcal fibrinolysis described by Tillett and Garner (1934) was shown by them to yield evidence of an immunity response, in that during convalescence from hæmolytic streptococcal infection the fibrin became resistant to solution by cultures of hæmolytic streptococci. Hadfield, Magee, and Perry (1934) showed that similar resistance to fibrinolysis was found in the blood from cases of rheumatic fever, and Myers and Keefer (1935) confirmed this, and further showed that such fibrin resistance was not found in rheumatoid arthritis.

In a previous paper a technique for the measurement of hæmolytic streptococcal fibrinolysis was described (Stuart-Harris, 1935). Three times the standard deviation plus the mean of the results obtained in 72 normal individuals was chosen as the limit for the normal time taken for fibrinolysis (51 minutes). Using this figure to assess the results in diseased individuals, susceptibility to fibrinolysis was defined as lysis within the time limit of normality, and resistance to fibrinolysis as lysis in a time greater than the normal limit. Resistance to fibrinolysis was further subdivided so that incomplete or total lack of solution of fibrin clots after 24 hours of incubation was delimited as maximal or "complete" resistance, in contrast with complete solution in a time not exceeding 24 hours which was termed partial resistance. It was shown that of 72 normal persons only 1 was partially resistant and none "completely" resistant to fibrinolysis. Of 38 cases of proven hæmolytic streptococcal infection 12 showed partial and 5 "complete" resistance; while of 60 cases of non-streptococcal infections 6 showed partial and 1 "complete" resistance. From this it was concluded that the presence of resistance to fibrinolysis was related to hæmolytic streptococcal infection, particularly if the resistance was of maximal degree. It was further shown that in streptococcal tonsillitis and pharyngitis, resistance to fibrinolysis, if it occurred, was found in the second or third week after the onset of the infection. This work has now been extended to include cases of chronic arthritis, rheumatic fever, and scarlet fever, the results of which are here reported. Table I. gives the summary of the results. Fig. 1 shows the

actual fibrinolysis times recorded for each case (maximal figure recorded for each case except for rheumatic fever), and Fig. 2 expresses the percentages in each group showing partial and "complete" resistance.

CHRONIC ARTHRITIS

In the arthritic group 60 cases of rheumatoid arthritis in every stage of the disorder, 6 cases of osteo-arthritis, and 4 cases of fibrositis, gout, and gonococcal arthritis were examined. Some of the cases of rheumatoid arthritis were kindly selected by Dr. George Kersley of Bath, who also collected the blood. Partial resistance was found in 4 cases (5·8 per cent.) and "complete" resistance in 2 (2·8 per cent.). All the resistant cases were examples of rheumatoid arthritis, and the only feature common to the patients was that they had undergone recent rapid improvement. One or two similarly improved patients were, however, susceptible to fibrinolysis, and the results in this group were not considered abnormal.

RHEUMATIC FEVER

A total of 70 children and adults representing every stage of the disorder have been examined—many at frequent intervals over considerable periods of time.

Convalescent Rheumatism.—By the kind coöperation of Dr. N. Gray Hill, of Queen Mary's Hospital, Carshalton, a group of children who were patients at a convalescent home was examined. All had

definite histories of rheumatic manifestations or had definite signs of cardiac lesions. They all had normal sedimentation-rates, and as far as could be ascertained had had no recent activity of the rheumatic process. Amongst this group there were 7 (31.9 per cent.) with partial resistance and none with "complete" resistance. This affords a basis for comparison with active rheumatic cases.

Active (Acute and Subacute) Rheumatism.—There were 48 patients who were active and of these 29 (60.0 per cent.) had resistance, of which 8 (16.8 per cent.) had "complete" resistance. The degree of activity was assessed with the help of the sedimentation-rate and the fibrinolysis times corresponding to the greatest activity are the basis of these figures. The active cases may be divided as follows:—

(a) *Cases with Congestive Heart Failure.*—It was difficult to assess the degree of activity in these cases. There were 4 cases, of which only 1 showed resistance.

history of recent throat infection, about ten days to three weeks prior to the rheumatic manifestations. Such a history was sometimes obtained among the children but much less frequently. It was, therefore, difficult to explain the presence of resistance in patients without foci of infection or without histories of sore-throats unless this was related to the rheumatic phenomena.

The next point to be considered is the change in resistance to fibrinolysis during the course of the disease in the individual case. Most of the patients in the active group were examined subsequently when the process had become inactive or less active (5 patients died in all). The most common event was a restoration of the fibrinolytic time to normal or towards normal as the patient recovered from the active stage. However, there was a lagging behind of the fibrinolytic time as compared with clinical activity and sedimentation-rate. The result was

FIG. 1.—Distribution of fibrinolysis times in the various patients.

(b) *Cases with Chorea as the Dominant Symptom.*—Although some of the other patients had choreic movements, yet these were overshadowed by other more grave signs. The 5 patients with chorea only did not show definite cardiac or other signs. One only showed resistance, although one of the other patients when convalescent, developed resistance after an attack of acute tonsillitis.

(c) *Cases with Carditis, Arthritis, Nodules, &c.*—These were subdivided into two groups according to age, under and over twenty years of age. The group under twenty showed the highest percentage of resistance—69 per cent. No difference was observed between first attacks and relapses of acute rheumatism.

It seemed that children with acute arthritis with definite swelling of the joints showed high figures slightly more often than those with nodules or pure carditis. The adult group showed resistance less frequently than the children when the effect of a definite focus of infection was taken into consideration. Thus of 10 adults 6 were resistant but 2 of these had recently had nasal sinusitis and 1 had had acute mastoiditis. As these foci were probably due to hemolytic streptococci the presence of resistance in these patients might have been due to the infection rather than to the rheumatic manifestations. The remaining 3 with resistance gave a

that often by the time the patient had become inactive the fibrin was still resistant. This was confirmed among the cases at the convalescent home; the first reading after admission to the convalescent home might be partial resistance although the patient was clinically inactive, but eventually the resistance disappeared, although some few patients were still resistant even at the time of discharge. During the active stage, however, there was no correlation between the degree of activity and the degree of resistance in different cases. The fact that there was such difference between the various cases might be taken as an argument for minimising the significance of the reaction. However, when the protean nature of the manifestations of rheumatism are considered and the total lack of agreement between different cases when viewed over a period of time, it is scarcely to be wondered that blood changes also differ widely. Certain of the cases showed the first rise in resistance when the activity was subsiding. This was particularly well marked in two cases with carditis alone. Another point deserves mention. It has seemed that the rheumatic patients with very high figures such as "complete" resistance have on the whole done better when followed over a few months than those who have

not had this high degree of resistance. The type of case with "complete" resistance was often the patient with acute arthritis with or without carditis. Such patients often had a straight-line sedimentation-rate during their stay in hospital, the line being a falling one throughout, and it seemed as though by the time they were admitted the disease process had already been overcome and convalescence had set in. Like all generalisations this statement is probably only roughly true and at least one patient has been seen who was "completely" resistant and who nevertheless relapsed while in hospital with chorea and pericarditis. When this episode was over the resistance again returned to a high level and the immediate history was satisfactory.

Finally, the effect was studied of intercurrent streptococcal tonsillitis and pharyngitis in 13 children convalescent from various rheumatic manifestations.

One child only had been recently active and she was the only one to suffer relapse into active rheumatism (nodules) within three weeks of the throat infection. Eleven children showed resistance to fibrinolysis, 6 being "completely" resistant, and although only one of these children was examined prior to the infection so that proof that the resistance was related to the infection was not absolute, the figure of 85 per cent. with resistance must be compared with that of 32 per cent. for the remaining convalescent rheumatic patients. Two conclusions follow from these observations. (1) Mere throat infection, without subsequent rheumatic activity, will produce resistance to fibrinolysis, so that the whole of the findings in the active rheumatism group might be caused by throat infections preceding the rheumatic disease. (2) Comparing the rheumatic children with tonsillitis with the 18 cases of streptococcal tonsillitis in non-rheumatic children and adults examined in the early part of this work it is seen that 85 per cent. of the rheumatic patients and 39 per cent. of the non-rheumatic patients showed resistance (Fig. 2).

SCARLET FEVER

A detailed study has been made of 58 patients selected from a possible 301 patients admitted to Plaistow Fever Hospital suffering from scarlet fever during the period of observation. The patients were all under the care of Dr. Donald MacIntyre, and clinical notes were kindly made by Dr. S. L. Wright who collected all the specimens of blood. The group includes all patients with heart and joint and some with kidney lesions seen during the whole period, and this accounts for 11 of the series. The remaining patients comprise 42 without sequela and 5 with various septic lesions. The fibrinolysis time was estimated weekly in some cases and at random in others. Resistance to fibrinolysis was encountered in 15 patients (26 per cent.), but 8 of these belonged to the group with heart, joint, or renal lesions, and of this group 73 per cent. showed resistance to fibrinolysis at the height of the complication. It was only possible to determine the time of onset of

FIG. 2.—Percentage resistance to streptococcal fibrinolysis.

resistance to fibrinolysis in straightforward scarlet fever in a few cases but, as in streptococcal tonsillitis, the second or third weeks appeared to be the time of onset of the blood change.

For the following clinical notes I am indebted to Dr. MacIntyre and Dr. Wright. The 42 uncomplicated cases were all of typical mild scarlet fever and only 4 were of interest in that joint pains were complained of during the first week of the disease. No prolongation or secondary rise of temperature occurred and the pains were perhaps toxæmic in origin. The 5 patients who developed resistance to fibrinolysis differed in no way from the remainder, and did not complain of joint pains. The cases with septic sequelæ included 2 with otorrhœa, 2 with mastoiditis, and one with nasal discharge. The mastoid cases alone showed resistance to fibrinolysis which was present in one patient before the onset of the mastoiditis, disappearing as this developed, and in the other after suppuration had ceased.

Table II. shows the clinical details of the 11 patients with non-suppurative sequelæ. Two had albuminuria, one had fever and joint pains in the second week, and eight had varying combinations of arthritis, carditis, and nephritis. All but 1 of the 11 patients showed a quiescent period of about two weeks between the initial fever and the onset of the complication, some experienced a second sore-throat during the illness varying in time relation with the complication, and all experienced a constitutional reaction with fever at the onset of the complication. The case without quiescent period developed acute arthritis and carditis on the second day of typical scarlet fever, having received antiscarlatinal serum the day previously (W. S.). The other 8 patients with arthritis and carditis would have been described formerly as post-scarlatinal arthritis and carditis. Four, however, had either had rheumatic fever or presented cardiac lesions on admission, and the phenomena observed appeared to be relapse of previously acquired rheumatism. The 4 other patients without rheumatic histories or lesions developed closely similar phenomena (pericarditis and arthritis, endocarditis and arthritis, or endocarditis alone), and

there seems no justification for regarding them as other than newly acquired rheumatic disease.

Of the 11 patients, 8 showed resistance to fibrinolysis, 3 being "completely" resistant (27.2 per cent.). The 3 patients without resistance include W. S., examined once only on the second day of the disease, W. J., examined only after carditis had been in existence for three weeks, and K. M. in whom the presence of the suppurating lesion might have affected the blood change. Only one of the patients with resistance was examined before the onset of the complication (S. H.), and in her the onset of albuminuria was correlated with the development of resistance. In the remaining patients resistance was present at the onset of the complication and persisted in some cases for weeks.

DISCUSSION

It follows that hæmolytic streptococcal infection is closely related to the disease rheumatic fever and

blood of patients with rheumatic fever is resistant to fibrinolysis, particularly during the active stage of the disorder or after intercurrent streptococcal infection during convalescence from activity. (3) The blood of patients with scarlet fever is resistant to fibrinolysis within three weeks from the onset in a minority of individuals and resistant in a majority of those patients with heart or joint sequelæ. (4) Hæmolytic streptococcal infection is considered to be related to rheumatic fever but not to rheumatoid arthritis. (5) Hæmolytic streptococcal infection of the respiratory tract in a rheumatic subject probably differs from similar infection in a non-rheumatic subject.

This work was commenced under tenure of a Lawrence scholarship at St. Bartholomew's Hospital; the expenses of the major portion were defrayed by a grant from the Medical Research Council. I desire to thank the physicians and surgeons of St. Bartholomew's Hospital for permission to study cases under their care, Sir Frederick Menzies for

TABLE II.—Non-suppurative Sequelæ in Scarlet Fever

Patient.	Age.	Clinical features.	Day of onset.	Past history.	Heart on admission.	Streptococcal fibrinolysis time.

not to rheumatoid arthritis if the evidence is accepted that the blood change under discussion is due to such infection. Even accepting this conclusion the site of the streptococcal infection in rheumatic fever cannot be decided, although other observers (e.g., Coburn, 1931) have brought forward evidence for the belief that the throat is the responsible focus in rheumatic fever. The results presented above suggest that such infection occurs in a high percentage of cases of rheumatic fever. Either rheumatic subjects repeatedly suffer from throat infections differing in frequency only from those of non-rheumatic subjects, or the response of the rheumatic subject to the streptococcal infection is different from the non-rheumatic response. The results obtained in cases of scarlet fever certainly lend support to the latter alternative, suggesting that resistance to fibrinolysis, though developed in a proportion of cases of uncomplicated streptococcal infection, is more developed in those patients with rheumatic and possibly nephritic manifestations.

SUMMARY

(1) The blood of patients with rheumatoid arthritis is susceptible to streptococcal fibrinolysis. (2) The

permission to study cases at several of the London County Council hospitals, and Dr. Donald MacIntyre for permission to study cases at Plaistow Fever Hospital. Finally I wish to thank Prof. Francis R. Fraser, of the British Postgraduate Medical School, for much advice and criticism.

RHEUMATOID ARTHRITIS BELIEVED TO BE OF TUBERCULOUS ORIGIN

A REPORT OF TWO CASES

By W. S. C. COPEMAN, M.B. Camb., M.R.C.P. Lond.

PHYSICIAN TO THE BRITISH RED CROSS SOCIETY'S CLINIC
FOR RHEUMATISM; ASSISTANT PHYSICIAN, WEST
LONDON HOSPITAL, CHILDREN'S DEPARTMENT,
AND TO THE HOSPITAL OF SS. JOHN AND
ELIZABETH; AND

R. D. CLAY, M.B. Lond.

HOUSE PHYSICIAN AT THE HOSPITAL OF SS. JOHN AND
ELIZABETH

THE idea that polyarthritis in adults may sometimes be due to obscure tuberculous foci of infection is not original: the name of the late Prof. Poncet of Lyons is linked with this hypothesis. In England and America, however, it has never been accepted, and we have found only two references to the subject in English medical literature during the last sixty years.^{1 2}

In the two cases to be described here there was reason to suspect a tuberculous aetiology, and after full examination it was decided to try the effect of a minute injection of tuberculin. The results of these injections proved sufficiently interesting to merit publication; since, taken in conjunction with the other investigations described, they suggest that other cases of rheumatoid arthritis might prove to be of tuberculous origin if they were studied from this point of view.

CASE RECORDS

CASE 1.—Mrs. A., aged 49; housewife. Admitted with a history of multiple arthritis since April, 1934, following tonsillitis. The feet and hands were then swollen and the shoulders were painful. Both knees were fixed, but after a visit to Bath only the right knee remained stiff. In December, 1934, this knee was manipulated under an anæsthetic, after which a slight degree of painful movement became possible. But later the swelling and pain in the hands and feet returned and had persisted until admission on August 10th, 1935. The small joints then showed peri-articular swelling and slight limitation of movement. The knees, elbows, and shoulders were all slightly painful on passive movement. In the right knee flexion was extremely limited. The chest showed very slight flattening of the right apex but no adventitious sounds were heard. No other abnormal physical signs, other than some degree of pallor, were detected. It was found that both the patient's parents had died of tuberculosis, but the patient herself had always been healthy except for pneumonia in December, 1933.

Radiography of the right knee showed general decalcification and a small erosion at the joint surface. The left first metatarsophalangeal joint showed absorption of cartilage, roughening of the articular surface, and some lipping. The cervical spine showed erosion and absorption of discs C. 4-7, with slight lipping in the lower dorsal region (Dr. G. T. Loughborough).

The intradermal tuberculin tests were as follows:—

Mantoux (O.T.) 1:10,000,	
at 24 hours erythema and induration	2×2 cm.
" 48 " " " "	2.5×2 "

The test was repeated using Parke Davis's "protein purified derivative" (P.P.D.) tuberculin which is claimed as a more specific substance than O.T. The results were:—

P.P.D. 0.00002 mg. at 24 hours showed erythema and slight	
induration 5 mm. diameter.	
" 0.005 mg. " 24 hours showed erythema and induration	2.5×2.5 cm.
" " " 48 hours showed erythema and induration	5 cm. $\times$ 3 cm.

Thus these tests were strongly positive. There was no focal or general reaction. The complement-fixation test for tuberculosis was also positive (+ ± ± 0).

The sedimentation-rate was 5 mm., 25 mm., 65 mm. (Westergren's method). A sample of blood was sent to Prof. E. Löwenstein of Vienna, the result ultimately returned being negative for the tubercle bacillus.

On August 22nd a subcutaneous injection of tuberculin 0.0001 mg. (T.R.) was given. On the next day the site of the injection was red and indurated (7 cm. diameter). All the joints were more painful, especially on full extension. Headache and malaise were complained of although there was no rise of mouth temperature. The rectal temperature was 1° F. above normal. On the next day rales were noticed at the right apex and the percussion note was impaired. The chest was accordingly radiographed and an area of irregular mottling "possibly due to tuberculosis" was seen. Three days later the general malaise and headache had disappeared but the small joints were very painful and the swelling of all affected joints was rather increased. The rales at the apex of the lung were no longer heard and a further X ray examination showed that the mottling was still present but less in extent than in the previous film. The sedimentation-rate was now 7 mm., 18 mm., 78 mm.

The joints which were painful were treated with hot paraffin wax, and calcium acetylsalicylate was given in moderate doses by the mouth. On discharge on Sept. 12th the reaction had disappeared and the swelling of the small joints was rather less than on admission and considerably less painful. No change could be detected in the right knee which had only a very slight painful range of movement. The chest condition appeared to be quiescent, but in spite of the decrease in clinical symptoms the sedimentation-rate of the blood had increased to 20 mm., 25 mm., 72 mm.

The patient is now reported (Oct. 12th, 1935) to be improved as to the joints, but to have a slight cough without sputum.

CASE 2.—Miss B., aged 20; window-dresser. The history started in 1931 with sudden pain and swelling of the left knee with headache and malaise. The patient was put to bed for six weeks after which the pain, but not the swelling, disappeared. In March, 1932, the knee again became painful and she complained of palpitations. There was then comparative quiescence until March, 1933, when the same trouble occurred. After a month in bed, with treatment, the swelling disappeared for the first time since its onset. The other knee, however, was at this time slightly swollen and she complained of extreme fatigue and pallor. She was treated by one of us, for wasting of quadriceps and the swelling, at the B.R.C.S. Clinic for Rheumatism, and subsequently sent to a convalescent home. While there, she developed pain in both sacro-iliac joints and the swelling returned in both knees. In November, 1933, these were put into plaster till December. On removal of the plaster the pain and swelling recurred, so the knees were replaced in plaster until February, 1934. She was meanwhile receiving treatment on general lines for her condition.

On admission in May, 1935, the Wassermann was negative as was the complement-fixation test for gonorrhœa. The blood sedimentation-rate was much raised (i.e., 66 mm.—90 mm.). Radiography revealed no evidence of spondylitis and no changes in knees except a general decalcification (Dr. S. G. Scott); the joint fluid yielded no evidence of tuberculosis. A number of brown scars were discovered on the front of the legs and ankles and it appeared that in 1934 the patient had suffered with a superficial ulceration of the tubercloid type which cleared up under treatment at St. Bartholomew's Hospital. An exploratory arthrotomy of the right knee-joint had also been carried out there and areas of non-specific inflammation were found which were said not to give definite evidence of tuberculosis.

The patient was again admitted on July 11th, 1935, to the Hospital of SS. John and Elizabeth, when her general condition seemed to be improved but both knees showed peri-articular swelling. There was little limitation but some pain and considerable crepitation on movement. The temporo-maxillary joint was also stiff and painful. There was no rise of temperature. The X ray changes showed now "a moderate degree of kyphosis. The sacro-iliac joints both showed increased density of bone in joint

areas with a blurring of detail in upper right portion. There was general decalcification" (Dr. Loughborough). The blood sedimentation-rate was still raised (58 mm.-101 mm.) and the complement-fixation test for tuberculosis negative. Apart from the ? tuberculous ulceration which had occurred in 1934 there was no history pointing to tuberculosis, and radiography produced no evidence of pulmonary tuberculosis. The Mantoux test, however, was positive at 1:10,000 with O.T. and intensely positive with P.P.D. tuberculin (kindly supplied by Messrs. Parke, Davis and Co.).

Five days after the first of these test injections an area of induration surrounded by a zone of erythema appeared on the right leg near the old scars. It increased to 3 cm. in diameter and was diagnosed (Dr. G. Dowling) as being "probably of a tuberculous nature." On the ninth day from the first intradermal injection of tuberculin a general and focal reaction occurred. The temperature rose to 100° F. and there was pain and swelling in the right ankle followed a few hours later by a similar condition in both knees which became hot, red, and swollen. The blood sample taken at this period and sent to Prof. Löwenstein was subsequently returned as positive for tubercle bacilli. Pyrexia, with headache and feeling of great exhaustion, continued for seven days reaching a maximum on the third day (100.8° F.). The swelling of the knees then also subsided but the ankle remained swollen and painful for a further ten days. Subsequently the patient stated that she felt much better. The ulceration disappeared leaving a strongly pigmented brown scar and the movement in all the joints was full and

painless. She was sent to a convalescent home. Her blood sedimentation-rate on discharge was 85 mm.-116 mm.-140 mm.

SUMMARY AND CONCLUSIONS

These two women with rheumatoid arthritis both responded to the injection of a minute dose of tuberculin by a general pyrexial reaction. A focal reaction also occurred in all the affected joints, and in one case lasted for ten days. In addition to these reactions, in Case 1 an area of hitherto undetected infiltration of the lung was rendered evident by the appearance of physical signs, confirmed radiographically, while in Case 2 a cutaneous tuberculide developed on the leg shortly after the injection. This ultimately healed. Most of the pathological tests usually employed for the diagnosis of tuberculosis were positive in both cases. Samples of blood were sent to Prof. Löwenstein for examination by his special methods, and in Case 2 the report was positive. We believe that an unsuspected latent tuberculous focus was present in each case and was activated temporarily by the injection of tuberculin. Such a focus might prove to be the underlying cause of rheumatoid arthritis in other cases.

CLINICAL AND LABORATORY NOTES

SPONTANEOUS SUBARACHNOID HÆMORRHAGE

By H. D. PICKLES, M.C., M.R.C.S. Eng.
AND

A. H. DUNKERLEY, B.Chir. Camb.

We thought this case worth recording because of its dramatic onset when one of us was present and because of the characteristic train of symptoms and physical signs.

The patient was a man, aged 58, who had worked as a cellarman for many years. He had long complained of several symptoms. The first was indigestion, but radiography of the stomach on two occasions had revealed no cause of this. The second was difficulty in swallowing, but here again X ray examination was negative, though the radiologist remarked on the excessive calcification of the arteries. The patient's features were so typically tabetic that a Wassermann test had been done a year previously, but this was negative. He also had a striking raw-beef tongue with a "scrotal" surface. There was no history of headaches.

On Jubilee Day he rose at 7.30 A.M. and had a large breakfast at 8.15; he brushed his clothes, got the coal in, and was watching part of the town's Jubilee procession when he suddenly experienced intense headache, and had to sit on the doorstep. One of us arrived within a few minutes and after examining him asked if he felt sick, to which he replied "No"; but a few seconds later he vomited violently and then collapsed and became unconscious. His breathing was stertorous and he vomited off and on for three hours. He then partially recovered and was able to answer questions, though with difficulty, as he had a partial aphasia accompanied by a right-sided paresis.

The headache was the chief complaint and as an injection of morphia gave little or no relief lumbar puncture was performed early the next morning under great difficulties, since the patient was lying on a billowy feather-bed. The result was most dramatic, the patient falling asleep while the needle was still in position. Almost pure blood was obtained under great pressure, and was shown to be spinal fluid containing blood, and not due to the needle

injury, by the following criteria: (1) blood was equally present in three separate lots of fluid; (2) there was no clotting; and (3) the supernatant fluid was blood-stained. The urine contained no albumin but a definite trace of sugar. Head-retraction was conspicuous from the beginning and continued to the end.

Except for intervals of two to three hours on the third and fourth nights of the illness, when the patient had two further hæmorrhages, he was conscious throughout and could make himself understood. Lumbar puncture was performed again on the third and the fourth days, since nothing else brought relief to the severe headaches and the patient always slept for several hours after it. The spinal fluid was still under great pressure on the third day and contained the same amount of blood, but on the fourth day there was considerably less.

Ophthalmological examination was extremely difficult because of photophobia, and nothing definite could be ascertained. As is usual in these cases the clinical signs were astonishing in their changes from day to day. Day after hæmorrhage: right pupil normal and reacts to light; left pupil enlarged and not reacting to light; knee-jerks sluggish; tendency to plantar extensor response on the right side. Second day: pupils now both equal and reacting to light; right knee-jerk active; extensor plantar response on right side. Third day: pupils both very contracted and scarcely reacting to light.

A further extensive hæmorrhage took place on the morning of the fourth day from the onset, and the patient's respiratory centre failed. A post-mortem examination was unfortunately refused.

Westerham, Kent.

A CASE OF AGRANULOCYTIC ANÆMIA

By HELEN M. GREGORY FOSTER, M.R.C.S. Eng.
AND

MARGARET DOUGLAS, M.B. Lond.

This is the record of a case of extreme granulopenia, though not of true agranulocytic angina, which responded to treatment with pentnucleotide. The patient was suffering from rheumatoid arthritis, for which she had been taking Novalgin in therapeutic

doses over a period of five years until she became acutely ill.

The patient was a woman aged 48 who, when first seen on March 21st, 1935, had been ill for five days, the illness starting with a cold. After the cold, she had severe headache, swelling of the face and neck, and mental

10 c.cm. pentnucleotide was given each day. At the end of that time the leucocytes had risen to 5000, with 63 per cent. polymorphs, and the injections were discontinued.

On March 30th a generalised erythematous rash appeared, of unknown cause but apparently toxic in origin; a week later jaundice developed, with bile in the urine and pale stools. At this time there was destruction of both red and white cells, the red cells dropping to $4\frac{1}{2}$ million and the white cells to 1260. Injections of pentnucleotide were started again therefore, and continued, at first daily and later on alternate days, until the white cells had again reached 5000 and had remained stationary at that point. The general condition of the patient was by this time very satisfactory; the temperature and the pulse were normal, the wound in the neck had healed, desquamation was taking place, and the jaundice had disappeared. From this time on convalescence was smooth; the blood picture did not change, the white cells remaining 5000 per c.mm. with 60 per cent. polymorphonuclears.

The illness lasted three months and the patient has remained well up to the time of writing. The blood picture on Nov. 29th was: red cells, 4,000,000; white cells, 8000; polymorphs, 81 per cent. The patient had a sty at the time of the last blood count, and responded to the infection.

Recovery in this case was due to treatment with pentnucleotide, as no other specific remedy was used, and the blood picture showed that improvement started within 24 hours of the first injection, contrary to expectation. There was after each injection a definite reaction: the temperature rose and the respiratory rate increased; there was precordial distress, dyspnoea, headache, and mental dullness. In the early days this reaction was not so marked, as headache and mental dullness were part of the general picture of the illness; but as the patient improved, and the

toxæmia disappeared, it became clear that the reaction occurred some hours after each injection of pentnucleotide, lessening in degree as the patient became more convalescent.

This case appears to belong to the group of granulopenia associated with certain drugs, the condition being discovered as the result of a general infection which the patient was unable to localise owing to her lack of granular cells. Localisation in the neck took place after the rise in the number of white cells which followed the injections of pentnucleotide. Amidopyrin is used in the manufacture of novalgin and the patient had been taking this drug in therapeutic doses for five years, with one interval of nine months, until she became acutely ill.

An interesting point is that since this last acute illness, the condition of the patient's joints has improved, movements being more free and walking easier.

We should like to express our thanks to Dr. Dennis Embleton and Mr. Cecil Flemming for their valuable help in this case.

Stanmore, Middlesex.

Chart of temperature and blood changes. The black rectangles show the dosage of pentnucleotide, which was at first 10 c.cm. twice daily, then 5 c.cm. twice daily, and later 10 c.cm. once a day or less.

distress. On this day she was gravely ill and delirious; the temperature was 103°F. , the pulse-rate 100, and on the left side of the neck below the jaw there was a diffuse hard cellulitis; in the mouth there was a mild ulceration of the gums and some oedema of the pharyngeal wall; there were sordes on the face.

A blood count next day showed that there were 6,000,000 red cells and 600 white cells, with 20 per cent. polymorphonuclears (see Chart). Treatment, started the same day (the sixth of the illness), consisted of injections of 10 c.cm. Pentnucleotide intramuscularly twice daily; no other specific treatment was given. General treatment consisted of the administration of much fluid with glucose, brandy, and champagne; Antiphlogistine was applied to the neck.

The blood picture began to improve on the day after the injections, the leucocytes rising to 2000 with 28 per cent. polymorphonuclears, although the general condition of the patient was worse; she was drowsy and the temperature was 104° . On the fourth day of the injections, signs of localised pus formation appeared in the area of cellulitis in the neck and an abscess was opened. A culture from the pus grew a mixture of *Staphylococcus aureus* and non-hemolytic streptococcus. On the fifth day of treatment the general condition of the patient was much improved; the temperature fell to normal; the leucocytes had risen to 2900, with 37 per cent. polymorphonuclears. On the next five days one injection of

PLEURITIC PAIN RELIEVED BY ARTIFICIAL PNEUMOTHORAX

IN A MAN OF EIGHTY-FOUR

By F. HARWOOD STEVENSON, M.D., M.R.C.P. Lond.
CLINICAL ASSISTANT TO BROMPTON HOSPITAL; LATE REGISTRAR
AND CHIEF CLINICAL ASSISTANT, DEPARTMENT OF CHILDREN'S
DISEASES, GUY'S HOSPITAL, LONDON

THE following case appears to be worth recording both in confirmation of the experience of Dr. Cedric Shaw¹ and in view of the advanced age of the patient, 84.

He was a small frail-looking old gentleman and was first seen on July 15th, 1935, in consultation with Mr. R. Trevor Jones. He had had a raised temperature for two days with cough and a very severe "catching" pain over his right lower chest. There were signs of consolidation in the right lower lobe and pleurisy. The old man sat in bed with a constant expression of anxiety on his face, grunting or suddenly uttering short sharp cries of

pain whenever he had taken any but the shortest and most judicious of breaths. Radiography showed patchy consolidation in the right lower lobe. There was no fluid.

On July 16th his temperature was lower but his condition appeared desperate. Lack of rest was obviously going to play a large part in the question of his recovery. The pain was now even more severe. An artificial pneumothorax was induced after an injection of omnopon gr. $\frac{1}{2}$, ephedrine gr. $\frac{1}{2}$, and atropine gr. $\frac{1}{100}$, 300 c.cm. of air being allowed to enter. The pressures before and after were: -2 -12 and +3 -10 cm. of water. The patient was much relieved although—a point of interest—the rub was by no means abolished. The next day the pain had to some extent returned and a 200 c.cm. refill was given, 0 -13 to +2 -9. For the next three days air could be detected in the pleural cavity and he was practically free of pain. On July 20th he had very slight pain and thereafter was entirely free. No more refills were given. His temperature had by now completely settled and he made a remarkably good recovery. On July 31st he was carried into the garden, just 15 days after the induction of his pneumothorax.

Radiological examination finally showed complete resolution of the lung. No fluid developed at any time.

¹ THE LANCET, Dec. 7th, p. 1280.

MEDICAL SOCIETIES

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION

At a meeting held on Dec. 10th, with Dr. E. PICKARD, the president, in the chair, Prof. WINIFRED CULLIS read a paper on

Physiology and its Debt to Medicine

She said that physiology and the medical and surgical aspects of medicine were so closely related that it was almost impossible to think of one without the other. It was the aim of the physiologist to find out the normal working of the body whilst the clinician tried (1) to prevent departures from the normal, (2) to restore normal functioning. A great difference between their methods of approach, however, was that while the work of the physiologist was essentially experimental, the duty of the clinician was to the individual patient. He could observe and study the effects of treatment but could only rarely carry out experiments with proper controls. In the not too remote past, physiologists had been looked upon by their clinical colleagues as a body of academic workers interested mainly, to quote a commonly used phrase, in "making frogs jump"! To-day, the teaching in the laboratories and in the wards was gradually coming into close relationship. As an example of the rapprochement, Prof. Cullis quoted the elucidation of the function of the parathyroids where the laboratory workers had demonstrated the effects of hypoparathyroidism and the clinicians those of over-activity of these glands. The debt of medicine to physiology was a well-worn topic and the classical examples of it were familiar to the point of boredom, but the reverse picture was less commonly presented. The extremely interesting work of Harvey Cushing showing the possible relationship of so-called "hyperacidity" to disturbances in the hypothalamic region fitted in with that of Beattie on the autonomic nuclei in this region. This again would perhaps link up with the recent production by Dods of changes in the gastric mucosa similar to those associated with chronic gastric ulcer, by subcutaneous injections of very large doses of pituitary extracts.

The discoveries of Banting and Best and of Minot were made by medical practitioners possessed with

a desire and a determination to treat and cure a specific disease. For the discovery of insulin, previous work, though unsuccessful, had indicated the line of attack, but at first there did not seem to be any real connexion between investigations by Whipple on the dietetic factors influencing the elimination of bile-pigments and the discovery by Minot of the liver treatment for pernicious anaemia. The connexion was there however, and it became clearer when Murphy and Castle added their contributions to Minot's researches. Prof. Cullis discussed the bearing on physiology of the work of Lucy Wills and of Helen Mackay in connexion with other anemias, and the flood of laboratory investigations which had followed Mary Walker's successful use of prostigmin in myasthenia gravis was the most recent example. Physiology and medicine were in essence different aspects of the same science, and workers in the one field could give immense help and stimulus to physiology from the clinical side.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

At a meeting of this society, held at Leeds on Dec. 13th, Mr. A. Gough delivered a presidential address on

Ovariectomy

He said that although the physical signs might lead one to make a diagnosis of unilateral tumour, it was always wisest to warn the relatives that both ovaries might have to be removed and also that tumours which appear to be innocent may possibly be malignant. In young people during the active period of sexual life, an effort should be made to preserve at least a portion of an ovary. The features suggestive of malignancy were solidity, satellite nodules in the pouch of Douglas, ascites, pain, and cachexia. A primary growth should always be sought for. In doubtful cases, X rays might be useful. The nature of the growth could only be ascertained by exploratory operation. Mr. Gough said that he had very seldom found the patient to be unfit for operation and had only twice refrained from operating because of extreme age and feebleness. In the presence of serious systemic disease, a short delay might get the patient into a safer condition.

Preliminary tapping was advised before removal of very large cysts. Removal by the vaginal route need hardly ever be considered. He favoured paramedian incision as this made provision for a stronger scar. Any adhesions should be separated, especially from the intestines, before emptying the cysts. The pedicle was best dealt with in small segments. Transfixing the pedicle involved danger of puncturing a vein, and it was best to cover the stump with peritoneum whenever possible. It was advisable to remove the second ovary when it was involved in the pathological process, in malignant cases; and in patients after the menopause.

Mr. Gough gave statistics of 180 cases, describing in detail the four fatal cases: of the whole, 126 were simple cysts; 25 were malignant; 16 were twisted; 7 were suppurating; and 6 had previously ruptured. These figures did not include follicular cysts or chocolate cysts of the ovary.

Corporeal Recurrence after Radium Treatment of Carcinoma Cervicis

Mr. P. MALPAS (Liverpool) said that corporeal recurrence of carcinoma cervicis is not a common condition. These cases gained importance from the fact that they represented the type of recurrence most amenable to further treatment. The speaker had encountered 5 cases amongst 359 cervical carcinomata treated with radium. The absence of gross cellular pelvic infiltration justified the performance of secondary hysterectomy. All the cases were Stage I. or Stage II. growths at the time of radium treatment; three of them were adeno-carcinomata. The syndrome produced by corporeal recurrence was late onset of irregular lower abdominal and lumbar pain indicative of uterine and renal distension, and a return of the watery discharge. On examination the uterus was found to be enlarged and globular. X rays showed ureteral obstruction. One of the patients died four days and another nine months later after operation, from uræmia. One died of very rapidly growing recurrence after remaining free from symptoms for five months. A fourth case remained well for 14 months and then began to show evidence of malignant distension of the colon. The last patient was still alive two years after the hysterectomy and five and a half years after the original radium treatment. In these cases excretion pyelography seemed to show ureteric obstruction, and relief after removal of the uterus. Mr. Malpas emphasised the importance of using a uterine applicator of sufficient length when treating cases of carcinoma cervicis by means of radium. In his view hysterectomy had no place in the secondary treatment of carcinoma cervicis until at least 12 months after radium had been applied.

Dr. J. W. BRIDE (Manchester) thought that recurrence in the body was much commoner than was usually surmised.

Mr. J. E. STACEY (Sheffield) thought that it was difficult to estimate whether the recurrence was corporeal or whether the body was secondarily involved.

Prof. MILES PHILLIPS (Sheffield) asked whether the corporeal growth could not possibly have been present at the time of the radium treatment.

Mr. M. DATKOW (Liverpool) said that he had operated on several cases after radium treatment for cervical cancer because the uterus had become mobile and the body had remained large, and had found corporeal growth present. In one of the cases

healing of the vaginal vault was greatly delayed and the patient suffered much pain.

Vitamins in Cases of Habitual Abortion

Mr. D. W. CURRIE (Leeds) described his results in the treatment by means of wheat germ oil of 30 patients who had suffered repeated abortions. Eighteen of these had reached full term, two the thirty-sixth week, and one the thirty-fourth week. The remaining nine pregnancies lasted over five months. Two of the 21 children delivered died subsequently. The presence of vitamin E was essential for the continuance of pregnancy to a successful termination; Mr. Currie therefore advised that in these cases 3 minims of wheat germ oil should be taken daily in capsules by the mouth, until the onset of labour.

Dr. RHODA ADAMSON (Leeds) said that she had treated with success, by means of wheat germ oil, several patients suffering from renal disease. Living babies were obtained; and her impression was that the children were inclined to be rather overweight.

Miss RUTH NICHOLSON (Liverpool) had treated two patients in this way, one of whom had aborted.

Prof. MILES PHILLIPS showed a specimen of sarcoma of the isthmus uteri, and Mr. J. E. STACEY a section of sarcomatous change in a fibroid.

ROYAL ACADEMY OF MEDICINE IN IRELAND

At a meeting of the section of surgery on Nov. 1st Mr. T. A. BOUCHIER-HAYES demonstrated a

New Photographic Method

The photograph, he said, was taken in the ordinary way and the resulting negative was then enlarged on to an X ray film. The final picture was much improved in this way. Even for such difficult subjects as the cut surface of the brain there was no need to use a filter, and artificial light made an ideal photographic illumination. The dark-room procedure was the same as for developing X ray negatives. By this method a permanent, light, and easily filed record was available, needing for demonstration only an X ray viewing-box.

Mr. J. J. MURPHY, radiographer to the Richmond Hospital, who was responsible for the technique of the method, said that the photographs of soft specimens were taken directly on a plain X ray film. These films were duplicated. It was possible to increase the high lights considerably, and if they went too high some of the surface of the film could be scraped off. No light filter at all was required. It was possible to use an X ray tank and developer, and this made it unnecessary to disturb the dark room as much as if a panchromatic developer was used. When enlarging, it was necessary to have a background which would not reflect light. The cost of the films was exactly the same as that of X ray films.

HOSPITAL SUNDAY.—There has been a decline in the collections for the Metropolitan Hospital Sunday Fund of £2684 since 1934, and at a meeting of the fund held at the Mansion House on Dec. 16th it was suggested that in future churches might group together to cover a whole parish instead of each making a separate collection.

REVIEWS AND NOTICES OF BOOKS

Health and Human Progress

By RENÉ SAND, Lecturer at the University of Brussels. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1935. Pp. 278. 10s. 6d.

Dr. René Sand, an international authority on public health, has in this volume brought together a vast amount of information on the scope and methods of what he calls "sociological medicine." This he defines as "the art of prevention and cure, considered in its scientific basis and its individual and collective applications, from the point of view of the reciprocal relations which connect the health of man with his living conditions." Dr. Sand takes a hopeful view of the advances that it is within the power of medicine to make towards the attainment of Aristotle's ideal of the good life. Medicine as he sees it is not limited to the subjects included in the medical curriculum, but takes account of all the conditions—biological, environmental, and economic—that menace the physical and mental health of mankind. He points out that a fund of knowledge has been accumulated which should empower a modern community to make the lives of its citizens far more healthy and complete than they are anywhere at the present time. By means of illustrations drawn from many countries he shows what has already been done to conquer disease and premature death, and not only to lengthen human life, but to make it more worth living; he indicates in what directions and by what methods further progress may be expected. Dr. Sand appreciates that we need more knowledge to deal effectively with the problems of health and disease; more complete and accurate statistics of social phenomena, for example, and a more general uniformity of statistical statement so that the recorded experience of different countries may be compared. He shows that official statistics may usefully be supplemented by non-official investigations such as those recently made in America by the Committee on the Costs of Medical Care. But what is more immediately needed is a fuller application of the knowledge that we already possess. His thesis is that human life could be made richer for all if we would take the trouble to make it so, and his stimulating and suggestive pages certainly bear out his contention.

The book, to which Mr. Édouard Herriot contributes a preface, may be recommended as a non-technical guide to citizenship and public welfare. Where so wide an area is surveyed a few slips are perhaps inevitable; for example, on p. 159 the relatively low infant mortality in Lancashire during the Cotton Famine is attributed not to the American Civil War but to the siege of Paris. Many readers will think that Dr. Sand underestimates the value of social insurance, and is unduly optimistic in his expectation that Soviet Russia could furnish "complete data" for statistics of morbidity; certainly the utility of the book would have been enhanced if the sources of the facts and figures quoted had been more precisely stated. The book as a whole, however, is of sterling merit. The translation from the revised French text has been well done by Dr. C. F. Marshall.

Arthritis and Rheumatoid Conditions

Second edition. By RALPH PEMBERTON, M.S., M.D., F.A.C.P. London: Baillière, Tindall and Cox. 1935. Pp. 455. 27s. 6d.

In its first edition this book marked an important advance in our understanding of and the methods

of approach to the arthritides. The subject was treated from all aspects, the biochemical section being particularly significant of the modern approach to the problem. Since that time the literature on this group of diseases has increased enormously, and the second edition takes note of the more important and useful of the contributions. Some new illustrations have been added to show more clearly certain stages of the pathology of the condition, and the section on the problem of infection has been elaborated and includes some new work on the rôle of the streptococcus. Several additions have been made to the so-called "dynamic pathology," notably on plasma proteins, phosphatase, acid-base balance, and water metabolism. The section devoted to the rôle of the intestine has been enlarged and incorporates a good deal of Fletcher's work and also a discussion of the relation of the conditions common to malnutrition and avitaminosis. Diet is considered in great detail; in the section on drugs and medicinal measures liver therapy is discussed. In all respects the book seems to have been brought completely up to date.

Puerperal Gynæcology

By J. L. BUBIS, M.D., F.A.C.S., Consultant in Obstetrics, Gynæcologist, Mount Sinai Hospital, Cleveland, Ohio. London: Baillière, Tindall and Cox. 1935. Pp. 200. 16s.

For nearly twenty years Dr. Bubis has advocated and practised the repair of injuries of the cervix, and pelvic floor, resulting from childbirth. In this book he describes the methods he employs, and records in detail results so startling in their excellence that they surely demand more than a passing attention. Realising that very few women are able to go through labour without some injury and that nature rarely cures even the smallest ones satisfactorily, Dr. Bubis holds that no laceration is small enough to be neglected. In 1916 he first attempted a procedure he had been planning for a long time, and operated shortly after childbirth to repair old as well as new lacerations of the birth canal. After the patient was delivered naturally of her tenth baby examination showed the presence of a lacerated cervix, a large cystocele, a relaxed perineum, and hæmorrhoids. Operation, advised years before, had been postponed on grounds of domestic obligations, expense, and timidity. One week after delivery a complete repair was performed and the results were all that could be desired. With improving judgment and skill the time between the delivery and repair was shortened and by 1920 it had become the routine procedure to repair all old as well as new lacerations immediately or shortly after childbirth, unless some surgical contra-indication presented itself.

The experience and results obtained in nearly 10,000 such cases seem to refute most of the objections that have been raised to this procedure. The claim that tissues are so œdematous, bruised, and distorted at this time as to render it impossible to differentiate between temporary and permanent disturbances is not apparently justified. Nor is there any evidence that healing is interfered with by the presence of lochial discharges. There seems moreover to have been no appreciable increase in the puerperal morbidity. This and a maternal mortality over so great a number of cases of under 2 per 1000 does not suggest that the performance of repair work

immediately following delivery adds in any way to danger of childbirth. Dr. Bubis states his belief that many are deterred from attempting this technique because they do not feel prepared to devote the extra time during the night or day to give this service. We do not believe that this consideration would weigh for a moment if the procedure were proved to be of advantage to the mother or to the community. Dr. Bubis claims that it is desirable on all grounds. His book is attractively written and will doubtless gain the serious consideration it demands.

A Practical Handbook of Midwifery and Gynaecology

Second edition. By W. F. T. HAULTAIN, M.C., F.R.C.S. Edin., M.R.C.P., F.C.O.G., Gynaecologist, Royal Infirmary, Edinburgh; and CLIFFORD KENNEDY, F.R.C.S. Edin., M.C.O.G., Assistant Gynaecologist, Royal Infirmary, Edinburgh. Edinburgh: E. and S. Livingstone. 1935. Pp. 356. 15s.

To condense the whole of obstetrics and gynaecology into some three hundred odd pages and without serious omissions, to include many recent developments, and to provide adequate illustrations is no mean achievement. Admittedly the result is difficult to read, since the text consists for the most part of tables and classifications. This is not a book suitable for the student beginning his work, but for one who wishes to revise the subject prior to examination, and the practitioner who needs a work for rapid reference will appreciate it. The matter is eminently sound and orthodox and is set forth clearly. A defect is that insufficient stress is laid on the relative ease or difficulty of the manipulations described as alternatives. Only six pages are allotted to the important subject of antenatal care. The book is excellently produced.

Clinical Parasitology and Tropical Medicine

By DÁMASO DE RIVAS, B.Sc. Biol., M.S., M.D., Professor of Parasitology in the University School of Medicine, and Assistant Professor in the Department of Pathology, University of Pennsylvania; in collaboration with CARLOS T. DE RIVAS, B.A., M.D., Pathologist to the Santo Tomas Hospital, Panama. London: Henry Kimpton and Co. 1935. Pp. 367. 22s. 6d.

THE object of the authors has been to give in this book the modern conception of tropical and parasitic diseases from the standpoint of cause, pathology, and symptomatology, with the complete life-histories of the parasites concerned. The method of diagnosis advised is a modified Telemann technique. In several respects the work is unsatisfactory. For example, under anthelmintics there is no mention of the active and lethal principle of oil of chenopodium or of the need to regulate dosage by its content in the oil; the need for participation of thymol is not emphasised, though it is on this that its efficacy depends. A mixture of equal parts of glycerin and a 30 per cent. solution of magnesium sulphate is highly recommended as a parasiticide, especially when followed by an injection into one or other end of the alimentary canal of a solution at 50°-54° C. with the intention of maintaining one of 45°-47° in the duodenum or rectum for 5 to 15 minutes. In the treatment of malaria hypodermic injections are preferred to intravenous ones, nothing

being said of the danger of the production of sloughing with unsightly scars or of the retention of quinine in local dead tissues; in the section on protection against malaria the fan or punkha is not mentioned. There are various contradictions and inaccuracies in the section covering nematodes, and the figures of *Mf. bancrofti* in the blood will not be found to resemble those described by other writers. It is unfortunate that the authors do not adhere to the International Code of Zoological Nomenclature. The sections on bacterial diseases and those of unknown causation which complete the volume are less challenging.

Infant Nutrition

A Text-book of Infant Feeding for Students and Practitioners of Medicine. Second edition. By WILLIAMS McKIM MARRIOTT, B.S., M.D., Professor of Pediatrics, Washington University School of Medicine; Physician in Chief, St. Louis Children's Hospital, St. Louis. London: Henry Kimpton and Co. 1935. Pp. 431. 20s.

THIS comprehensive monograph has been extensively revised, and though the book as a whole has been slightly decreased in size by the omission of matter belonging more properly to the domain of general paediatrics, new sections have been added. As might be expected, the principal changes are in the chapters dealing with vitamins and with allergy. The rôle of infection in the causation of gastro-enteritis is discussed with moderation. Prof. Marriott considers that there are two types of mastoid infection to be found in infants suffering from diarrhoea and vomiting: a primary type, the drainage of which will improve the gastro-intestinal symptoms, and a secondary type, occurring in the course of the disease and associated with an exacerbation of symptoms in which drainage cannot be expected to bring about equally good results. The work as a whole provides the clinician with a clear résumé of the scientific principles underlying the feeding of infants and the treatment of nutritional disturbance.

Anatomy of the Nervous System

Fifth edition. By STEPHEN WALTER RANSON, M.D., Ph.D., Professor of Neurology and Director of the Neurological Institute, Northwestern University Medical School, Chicago. London: W. B. Saunders Co., Ltd. 1935. Pp. 501. 27s. 6d.

THIS work has been revised and brought up to date without material addition to its bulk. Many references to recent important work have been incorporated, particularly in the section on the central visual pathway, a subject to which the author and his co-workers have made substantial contributions. Readers will be specially grateful for the list of references at the end of the book, a concession all too rare in works of this type. Additional illustrations have been grouped together as an atlas at the end of the text. These include photographs of Weigert preparations of whole coronal sections of the cerebral hemisphere at different levels. An excellent series of drawings of transverse sections of the brain stem at 20 levels has also been added: in each instance a sketch in profile of the brain stem has been marked to show the level illustrated, and explanatory notes complete the demonstration.

THE LANCET

LONDON: SATURDAY, DECEMBER 28, 1935

HOSPITALS AND THE RATES

PRINCE ARTHUR OF CONNAUGHT, presiding last week at the Court of Governors of Middlesex Hospital, usefully drew attention to the heavy burden of rates. The new buildings of the Middlesex, he said, had been considered as a whole for rating purposes by the Marylebone Borough Council; this meant some relief from the worst rigours of assessment; but in his view no recognised hospital should be rated at all. He criticised the anomalies of the present system whereby some hospitals (as at Newcastle) are not only de-rated but are actually subsidised, while some are assessed as if they were purely commercial undertakings; somewhere up and down the scale between these two extremes came others such as the Middlesex itself. "The municipal hospitals, working with us for the same purpose—the health of the community—and getting their medical officers from our training schools, are not merely free from rates but are paid for from the rates; we, who have to seek our income largely from the generosity of the public, are rated to subsidise those whose costs are provided from the rates—an inequitable and fantastic anachronism."

The unfair handicap of the voluntary hospitals in this respect is indeed notorious. Parliament has in time past been willing to exempt or relieve from rates such public buildings as churches and chapels and lighthouses, and also other semi-public institutions such as certain non-provided schools and scientific and literary societies. It would have needed but a slight extension of this principle to make the relief of hospitals a part of the general law of the land. I think that the law has conferred some benefit in

PRINCE ARTHUR did not explain his reference to Newcastle-upon-Tyne, but that ancient borough has certainly been public-spirited. The valuable site on Spital Tongues of the old Hospital of St. Mary Magdalene (certainly an almshouse rather than a hospital in the popular sense) enabled the corporation long ago to secure a scheme whereby, on the reorganisation of the charity, surplus revenue and capital funds could be applied to the aid of local medical institutions. A section in the Newcastle Act of last August authorised the corporation to contribute at discretion towards payment of the rates and taxes of another medieval hospital in the town and towards the cost of supplying it with gas, electricity, and water. The object of this generosity was again more almshouse than hospital, but the charitable principle is the same. Elsewhere we find other forms of assistance. A few years ago Brighton took powers to reduce its water charges to approved voluntary hospitals. Glasgow in 1929 exempted its voluntary hospitals and infirmaries from rates for education, lunacy,

and parish purposes. Dundee in 1927, and Kilmarnock and Troon last summer, secured authority to subscribe to local voluntary hospitals, and doubtless there are other and earlier instances. The trouble is that these reliefs are given rather as the exception than as the rule. To take money away from the hospitals with one hand and to give it back with the other is in any case a cumbrous and invidious procedure.

It is true that the great voluntary hospitals are, for various reasons, seeking more and more to enlarge the limitations of their charitable objects so as to obtain authority to accommodate paying patients. The St. Bartholomew's Hospital Act of last August is a recent example. By some this new departure may be deemed to fortify the idea that a hospital is a commercial concern. On the other hand, it has now become the national policy to assimilate the positions of the voluntary and the rate-aided institutions. We have seen agricultural and industrial properties de-rated in the endeavour to restore the general prosperity. To restore and maintain the health of the public is not less a national object. The voluntary hospitals may fairly be called a depressed industry. When will their turn come?

SEX HORMONES IN PRACTICE

KNOWLEDGE of sex hormones and their action has advanced astonishingly during the past few years, and it is generally recognised that their application will some day make much of our present gynaecological surgery unnecessary. Most clinicians leave it at that: they feel that the time has not yet come to experiment with these remedies outside the laboratory. This attitude is based partly on caution and partly on the fact that until recently effective doses of the hormones were impossibly expensive, while some of them remain so. It will be agreed that promiscuous administration of endocrine extracts is sometimes harmful and usually valueless; that they must be used only after careful exclusion of relevant organic lesions; and that the user needs a cautious understanding which can develop only from knowledge of physiology. But admitting all this, it seems to us that more interest should be taken, here and now, in the rational treatment of the menstrual and reproductive disorders that incapacitate so many women.

First let us consider inadequate menstrual loss. This may take the form of primary amenorrhoea in which a girl reaches adult life without having a menstrual period. In such cases there are usually signs of gross ovarian deficiency, the most important of these being an under-developed uterus—perhaps no larger than a hazel-nut. Such an organ, infantile in structure, is incapable of normal function, and the first aim of treatment therefore is to promote its growth. KAUFMANN¹ has shown that this can sometimes be done by giving large doses of the ovarian hormone known as oestrin or folliculin (e.g., 200,000 to 4,000,000

¹ Kaufmann, C.: *Proc. Roy. Soc. Med.*, 1934, *xxvii*, 41; *Jour. Obst. and Gyn. Brit. Emp.*, 1935, *xliii*, 409.

international units of crystalline oestrone). The next object is to induce growth of the kind of endometrium associated with normal menstrual bleeding. In an adult uterus this can almost always be done by giving the corpus luteum hormone, progesterin, in doses of 5-50 rabbit units. Assuming success in these two aims, the primary defect—ovarian deficiency—remains to be overcome; for the injection of ovarian extracts is merely substitutive treatment, and it is doubtful how far it can initiate spontaneous menstrual cycles. The fundamental object is to convert the infantile ovary into an adult ovary with normal function. In immature animals this can be done by injecting gonadotropic (gonad-stimulating) principles derived either directly from the pituitary gland or from urine excreted in pregnancy. It would therefore be reasonable in primary amenorrhœa to follow treatment of the uterus (with œstrin and progesterin) by administration of gonadotropic extracts; and there is in fact evidence that in a few cases this has led to the onset of cyclical menstruation. It has to be acknowledged that the extracts at present in use are seldom potent enough to produce any lasting effect on a seriously undeveloped ovary. But where the deficiency is not so great, and we have merely the condition of secondary amenorrhœa, treatment is more promising; and in oligomenorrhœa—so often associated with dysmenorrhœa or sterility—the outlook is far more hopeful. The principles of treatment here are much the same, but some authorities such as CLAUBERG² claim that œstrin by itself suffices for cure. He finds that in immature mice its injection may actually lead to the formation of corpora lutea, and since it is well established that œstrin has no direct action on the ovary this effect must, it seems, be due to stimulation of the pituitary. It has become evident that the ovary and anterior pituitary are complementary in action; too much œstrin depresses pituitary activity while too little makes it unusually apparent. CLAUBERG describes this as the "pituitary release phenomenon"; he believes that large doses of œstrin promote pituitary quiescence and that sudden cessation of them brings about abnormal pituitary activity sufficient to cause formation of corpora lutea in the ovary and consequent changes in the uterine endometrium leading to pregnancy. The dysmenorrhœa often associated with scantiness of menstruation responds, it is said, to œstrin therapy in some 30-50 per cent. of cases.

There are two other important conditions in which treatment with ovarian hormones is especially satisfactory. First, œstrin is found useful—in less heroic doses, and even by mouth—at the menopause. Hot flushes sometimes yield readily to relatively small doses such as 500-3000 international units of oestrone daily by mouth. Treatment induces a sense of well-being and may relieve associated disorders such as pruritus or kraurosis vulvæ and acne rosacea. Secondly, progesterin finds rational employment in

cases where repeated abortion in early pregnancy has no apparent cause, and the proportion of successful results is too high to be fortuitous.

A theoretical objection to using gonadotropic extracts (prolan) is that they may over-stimulate the ovary and thereby damage its function irreparably. This danger will certainly have to be reckoned with when extracts of greater potency become available, but those who have so far used such hormones—chiefly for excessive bleeding—do not seem to be much impressed by it. The results they record vary considerably. HENDERSON,³ for instance, says that he has treated 39 cases of menorrhagia and metrorrhagia with "anterior pituitary-like hormones," of which 31 were relieved and 25 returned to normal menstruation; of the 8 patients who failed to benefit 4 were proved to have local pelvic lesions sufficient to cause the complaint. GEIST and SPIELMAN,⁴ on the other hand, found that this hormone brought about improvement in only 2 out of 14 cases of the same kind, and conclude pessimistically that "the present widespread use of 'endocrine' products in menstrual disturbances seems to us unwarranted." Excessive uterine loss is attributed to lack of some anterior pituitary factor, or to insufficient pituitary stimulation of the ovary. Ripe Graafian follicles fail to rupture and luteal tissue is absent; the ovary is studded with relatively small follicular cysts; and the endometrium proliferates unduly and bleeds profusely. It is with the object of inducing luteinisation of the ovarian follicles and a progestational type of endometrium that gonadotropic hormones and/or progesterin are administered. Three factors commonly militate against their success. In the first place the patient often presents herself too late; the cases which respond best are those of bleeding at puberty, which are usually pure menorrhagia. Secondly, the doses of gonadotropic extracts at present available may often be too small to achieve their purpose. Finally, the present preparations may not contain the principle which is most effective in controlling uterine hæmorrhage.

MEDICINE AS A USEFUL ART

In a bookseller's catalogue which came by the same post as a copy of the inaugural lecture given by the new professor of medicine in the University of Liverpool, medicine and surgery are classed under the "useful arts," and Prof. COHEN's address gives good grounds for reflection as to how far such a definition is or ought to be true. What in short is the prime concern of a professor of medicine?—a question which is being discussed more and more as the academic equipment of the subject is being expanded in so many places. It is, without doubt and as the regulations of his chair likely enough prescribe, to advance medicine by teaching and research; the two are intimately connected, for nothing but second-rate teaching will be found in an atmosphere where there is

² Clauberg, C.: Deut. med. Woch., 1935, lxi., 1189.

³ Henderson, D. N.: Canad. Med. Assoc. Jour., 1935, xxxii., 617.
⁴ Geist, S. H., and Spielman, F.: Amer. Jour. Obst. and Gyn., 1935, xxix., 518.

no curiosity to know more, and good academic teaching is an almost necessary prelude to worthy research. And to carry out this ideal, the professor's first business must surely be to know about medicine; he must be what is sometimes nowadays esteemed rather lightly, a learned man and a scholar. And this not only for his teaching, for it is as true in medicine as in other disciplines of human interest that a good enough knowledge of what has been said and written already will give the solution of many problems which seem unsolved; we have the data if only we had the wit to put them together. About the necessity for learning there is, we imagine, little difference of sober opinion, and it is as idle as it is fashionable to waste time finding out what is known already; knowledge can be advanced only from a solid foundation, it cannot start in the air. Granting this, what is the professor to do next? Is it to be his chief aim to cure the sick and prevent illness or to study the origins, nature, and course of diseases without taking much count of the practical outcome?

The two roads have many connexions, but they are not the same. A pretty complete knowledge of the natural history of a disease does not necessarily lead to its prevention or cure, nor does the discovery of a cure always wait a knowledge of what is being cured. Irrational therapeutics (such as aspirin for headache) and rational therapeutics (such as insulin for diabetes) may both confer great benefits on the sick and it would be difficult to make a just estimate of which of these

two instances has been of most benefit to mankind, though there is little doubt as to which would be esteemed most highly by a healthy professor. Advances in medicine come from anywhere and almost everywhere, and we should say that the professors should go along any road which happens to appeal to them. To one it may be an abstract study of the chemistry of hæmoglobin, to another it may be a direct search for a cure of the common cold; given knowledge, industry, and brains one is as likely to advance medicine as the other. In the old Italian universities professorships were made life appointments to secure their holders from undue interference by their colleagues of the faculty of theology: equal freedom is needed nowadays and perhaps a little more sympathy between those to whom different paths appeal. There is only one thing which should be common to them all—the problems to which they pay attention must come from the study of sick people even if we agree with Prof. COHEN in thinking that SYDENHAM exaggerated the possibility of always finding the answers in the same way.

Clinical study is and will remain, as Prof. RYLE has reminded us,¹ the primary method of attack on clinical problems if only because the setting of a soluble question is generally half the difficulty in finding an explanation. Several of the dramatic advances of medicine in recent times have come in other ways, but the whole of modern practice is permeated with clinical improvements which are at least as grateful to the patient as the more sensational items.

ANNOTATIONS

CARBON DISULPHIDE AND ITS DANGERS

CARBON disulphide is unjustly known as a very evil-smelling liquid; the fœtor is not its own, but is due to minute quantities of undesirable associates. The B.P.C. remarks mildly: "It should not have a fœtid odour." Its dangers however are of a more tangible kind and not realised as fully as they should be. Those who work much with it in the laboratory have found it highly inflammable; even evaporation over a hot plate, with the burner turned out, will sometimes cause a fire, made more unpleasant by the irritating and poisonous sulphur dioxide formed on combustion. Hot steam pipes or electric bulbs will sometimes cause ignition, for its auto-ignition temperature is between 125° and 135° C. Special precautions are therefore needed when carbon disulphide is used in industrial operations, which it often is owing to its useful solvent properties, and its low boiling-point (46° C.), which enables it to be removed easily from articles on which it has been used. The risk of explosion is high as a mixture containing only 19 volumes in a thousand of air is explosive. But when all possible precautions have been taken against the risk of fire there is still the danger from the high toxicity of the vapour. Slight symptoms are produced after some hours' exposure to concentrations as low as 322 to 386 parts per million in air; the maximum concentration that can be inhaled for an hour without serious disturbance is 483 to 807 parts. Exposure for over half an hour to a concentration of 1150 parts is dangerous. Lower concentrations lead to chronic poisoning. The usual

effects of inhalation of the vapour for some weeks are nausea, indigestion, headache, and giddiness, sometimes accompanied by emotional disturbances which may be frankly hysterical in character. The breath has a characteristic odour, the tongue is pale and flabby, and there is facial pallor. In cases of mild absorption of the vapour, an appearance of anxiety with sweating of the hands and forehead is suggestive; these symptoms indicate a degree of exposure which, if continued, may lead to other effects. The mental disturbance increases and is accompanied by impairment of memory, mental dullness, and depression. The speech may be affected; contraction of the visual fields with diminution of accommodation occurs later. One of the earliest signs of chronic intoxication is muscular weakness due to a toxic neuritis. First to suffer are the facial muscles or the flexor muscles of the forearms, the lower limbs being affected later. Tremor, paresthesia, and loss of sensation are also seen, and, as a later complication, optic neuritis. Ultimately there is difficulty in walking; the patient may become bedridden and even unable to feed himself. Recovery is slow and uncertain; some effects may remain. In acute poisoning the mental disturbance may amount to mania.

Since Dec. 31st, 1924, poisoning by carbon disulphide contracted in a factory or workshop has been compulsorily notifiable to the chief inspector of factories by medical practitioners, and by occupiers to the district inspectors.² Since that date 18 cases have

¹ See THE LANCET, Dec. 7th, 1935, p. 1301.

² Ibid., 1934, i., 1299.

been reported from artificial silk works, viscose paper works, india-rubber works, and works manufacturing the compound. Practitioners who have among their patients chemical students, research workers, or analytical chemists would do well, if they find any of the symptoms which have been described, to make tactful inquiries as to whether the patients have been engaged recently in work involving the use of this compound, either as a solvent or as a participant in chemical reactions studied. The expert readily gets into the way of using well-known chemicals without much consideration of possible toxic effects, and soon becomes inured to the offensive smell which might give a useful warning to the inexperienced; the symptoms resulting from mild exposure may be attributed to ennui, fatigue, or unsuitable food. The liquid being heavier than and not very soluble in water, safe storage can be ensured. Since the vapour is about two and a half times as dense as air, ventilation from the bottom of rooms is effective. Care must be taken that the air-disulphide mixture sucked out by fans is not ignited by electric sparks or other sources of heat.

The dangers of carbon disulphide are described and precautions set out in a memorandum just issued by the factory department of the Home Office (Form 836, November, 1935, 3d.).

A FRIENDLY CRITIC OF OUR HYGIENE

WE do not think or talk of things that are going well, and when the public is vocal about reform of the marriage laws we know at once that something is wrong with the existing arrangements. Our friend who bores us about his digestion has certainly got a bad one. It is, therefore a compliment to English sanitation when Prof. Julius v. Darányi in his "Ausbildung in der Hygiene"¹ says:

"It is interesting that although health education in general is not very much developed in England the high standard of living has, nevertheless, made sanitary arrangements generally indispensable; they appear to be a matter of course, with no necessity for health propaganda being felt. It seems that in countries with a low degree of civilisation the situation is reversed. In them health propaganda is prominent because sanitary arrangements are imperfect."

It is true that we take many of our health services as a matter of course. We seldom speak about them, but they strike the foreign observer with greater force the more such facilities are lacking in his own country. This is probably the reason why Dr. Darányi elsewhere remarks that we do not give sufficient time to the teaching of hygiene in the medical curriculum. We are sixty years behind the German and Hungarian universities and still in the stage when hygiene is not separated from State medicine. But is that really so? There is in this country a definite perception of the difference between environmental sanitation and personal preventive medicine. Under the threat of a cholera invasion we began environmental sanitation about a century ago, blessed by a well-defined natural frontier and by a rapidly developing industrial system. It was easier to keep out infection at the sea coast than at a land frontier, and the industrial boom provided money for costly and slow-fruited environmental methods. We have had our reward. We believe that most of those who have decided to adopt medicine as a career have a sufficient general knowledge of environmental hygiene to make it unnecessary to

engage in its detailed study until the foundations for such study have been laid in a knowledge of physics, chemistry, and bacteriology. In the personal preventive medicine which has rapidly developed in the last quarter of a century it is wiser not to teach people how to prevent a particular disease until they have learnt something about the nature of that disease. But the position of the medical student in training to become a priest of the esoteric mysteries of hygiene is different from that of his lay brother who has to practise only the exoteric ceremonial. It is ultimately on the individual layman that the success of environmental hygiene must depend, and although we may afford to go slowly with the remodelling of the medical curriculum in preventive medicine, the time has come when sound teaching of elementary hygiene should take an increased place in the ordinary school course. Environmental medicine rests ultimately on cleanliness and the proper disposal of waste products; soap and water have much more to do with it than have special diets, dress reform, and such fancies. While the children in our elementary and secondary schools are learning unapplied chemistry and physics, the press is flooded with advertisements of vitamin-containing foods, artificial sunlight lamps and aperients, with ominous descriptions of the evils of blood pressure and intestinal stasis. The school medical officer might now supplement the routine medical examinations, which have enormously benefited the rising generation, with lectures on public health and hygiene as part of the science or domestic economy course at schools. Thus the seeds of wider and sounder knowledge—not of medicine or pathology, but of the principles of hygiene as they may be practised by the simple—would be disseminated; and it has been found in selected communities where the elements of hygiene are taught that the results have been encouraging. Ignorance does not create a state of hygienic bliss.

NATIVE FOODSTUFFS

THE superlative importance of foods is at last coming to be recognised even by the most ascetically minded. Food is the raw material of which man is made, and the recent meeting in London of international experts on nutrition, under the auspices of the League of Nations, showed that at last the governments are realising that it comes within the scope of their responsibility to provide that raw material in sufficient quantity and of adequate quality. The newer knowledge of nutrition has made it possible to sketch human requirements with a fair degree of definiteness. These may differ somewhat for different climates and certainly the exact mode of meeting them will differ according to the food-supplies naturally available in different geographical regions. It behoves all countries, therefore, to examine their native foodstuffs and ascertain which of these can best satisfy the different nutritional requirements of the people, in proximate principles, salts, and vitamins. It is gratifying to see that neither South Africa nor India is unconscious of her duties in this respect. For a good many years the proper nutrition of the native mineworkers on the Rand has been the subject of special study and we now have to hand accounts of two investigations by L. F. Levy and F. W. Fox,¹ of the South African Institute for Medical Research, in which the antiscorbutic value of a number of South

¹ Reprinted from the jubilee volume Orvosképzés. Budapest: University of Hygiene. Pp. 53. 3 pengő.

² South African Med. Jour., 1935, ix., 181; Biochem. Jour., 1935, xxix., 584.

African foodstuffs is worked out by indophenol titration and confirmed in some cases by biological tests. Indophenol titration is admittedly a rough method of estimating vitamin C, being subject to certain well-recognised sources of error, but its use serves to give a general idea of the vitamin-C content of foodstuffs. One material, lucerne, receives special attention, since the leaves were found to have a very high vitamin-C content, about four times that of fresh citrus fruit juice. Lucerne, which is a vetch, is widely used as a food for domestic animals—in South Africa especially for ostriches—but there seems to be no reason why it should not be adapted for human consumption as a salad or spinach, where there would otherwise be a shortage of fresh antiscorbutics. From Calcutta R. K. Chakraborty publishes a similar study,² in which special attention is paid to the antiscorbutic value of milk, human, cow's, goat's and buffalo's, and of foodstuffs of plant origin. Three fruits were found, species of zizyphus, physalis, and citrus, all of which were more potent sources of vitamin C than the best Indian fruits previously known, the Indian lemon and orange. Both the Indian and African studies will no doubt be extended and investigations of the same sort will eventually have to be undertaken in all parts of the world where the less usual foods are eaten.

ELEPHANTIASIS IN BANCROFTIAN FILARIASIS

DURING the last four years Prof. C. K. Drinker and his colleagues have been working on the lymphatic system of the dog. They have produced typical elephantiasis by repeated injections of two sorts given slowly into the lymphatic trunks of the lower limb—namely, a watery suspension of crystalline silica with particles about $1\ \mu$ in diameter, and a solution of quinine hydrochloride with a strength of 2.5 per cent. In the lymph glands the particles of silica get caught up in the endothelial reticulum of the sinuses, and these become filled with large pale cells which later form fibrous tissue; the effect of quinine in bringing about the closure of varicose veins is well known. These repeated injections, made at normal lymph pressures, act upon new collateral channels as they are formed; and the final effect is that, as the result of lymph blockage and transient periods of sterile inflammation produced by purely physical and chemical means, the part becomes typically elephantoid. Further inflammatory attacks are apt to occur in it, just as they do in elephantoid tissue in man; they last normally about 48 hours, and each of them adds to the amount of elephantiasis.

It has been much debated whether attacks of this kind, occurring in elephantiasis due to *Wuchereria bancrofti* infection in man, are caused by the filaria, adult or embryo, or by an added bacterial infection. Drinker has probably explained the different findings, on which these differing opinions are based, by showing that in the first few hours, and in the first few hours only, of such an attack in a dog a hæmolytic streptococcus is present in the œdema fluid from inflamed elephantoid tissue, and that this fluid can be obtained from a dependent leg without prior injection of salt solution. If this pointer is followed it should be possible to settle whether or not these attacks in man are due to bacterial infection seeded on to a suitable soil. That the elephantoid tissue does afford such a soil is seen in the fact that inflammatory attacks could be induced by injecting into it a small fraction of the number of streptococci needed to produce the same effect in a healthy animal. During

these attacks the lymph of the inflamed part has a high protein content, amounting to about half that of the plasma, instead of the normal percentage of about one; and in such a medium, used in vitro, connective tissue cells grow well. Further, when the rupture of dilated lymph vessels has allowed of escape of lymph through the epidermis, the protein content of the œdema fluid becomes low and the dog in question has shown little permanent fibrotic enlargement of the limb. The disadvantage of attempting to reproduce this state of affairs in man are clear, but there may be conditions in which upward drainage is possible. The means of doing so were apparently added to in the case of a woman of 19 with double elephantiasis nostras of the lower limbs. The obstruction was high up in the abdomen and by incising large lymphatic vessels lying on the iliac arteries the lymph was made to run into the retroperitoneal space—with what permanent result could not be stated when the report was published.¹

There is another feature in which these experiments have fallen in with experience in man. In the typical inflammatory outbreaks which have been mentioned the blood has at all times been free of bacteria: but in one dog, evidently as the result of infection by a more virulent strain of streptococcus, a septicæmia developed reminiscent of the grave cases which have been so striking a feature of Bancroftian filariasis in British Guiana. In these various ways the new methods used by the physiological laboratory of the Harvard School of Public Health have given a welcome impetus to the study and explanation of this infection in man.

LE ROY EST MORT!

ANY doctor who has tried to make even a tentative diagnosis solely on the patient's symptoms as described to him by a friend or relative knows how ludicrously he may be led astray. Mr. Yearsley is therefore to be congratulated on his courage in diagnosing the causes of death of the Rulers of England on what, in many cases, is very slender and unreliable testimony.² Perhaps, as may be necessary sometimes in surgery, he has had to learn not only to make up his mind but also to act on insufficient evidence. Be that as it may, and although we cannot unreservedly accept all his diagnoses, it must be admitted that he has written a very interesting little book. The Rulers of England, if Oliver and Richard Cromwell and the luckless Lady Jane Grey are included, number forty from the Norman Conquest to the death of King Edward VII. Of these, no less than eight (20 per cent.) died violent deaths, either in battle or at the hands of the murderer or headsmen, but it is reassuring to loyal subjects to note that the practice of regicide grows less common as time goes on. The acute infections and cardio-vascular-renal disease have each accounted for six; syphilis, congenital or acquired, and "dysentery," which covers a multitude of ignorances, have each disposed of four. "Senile decay," a diagnosis no longer accepted as a certified cause of death, is mentioned in three cases and implied in one other. Stephen may have had an appendix abscess, Edward III. gonorrhœa, and Richard II. anorexia nervosa, but Mr. Yearsley thinks that Henry I.'s "surfeit of lampreys" was more probably ptomaine poisoning. George IV. and William IV., pathologically speaking, had much in common; both had hepatic cirrhosis,

pericarditis and, probably, pneumonia. Those who think harshly of James I. will do well to bear in mind that he had Bright's disease, enlarged tonsils, renal calculi, jaundice, hæmorrhoids, dental caries and pyorrhœa, and arthritis—surely enough to sour any man.

THE WORLD REQUIREMENTS OF NARCOTIC DRUGS

THE Supervisory Body acting under the 1931 Convention for Limitation of Manufacture of Narcotic Drugs has completed its estimate of the world requirements of morphine and its derivatives, and of cocaine, for 1936. The estimates for morphine, heroin, and cocaine "for use as such" are respectively 9799 kg., 930 kg., and 4503 kg. Compared with the estimates for the two previous years these figures represent a substantial reduction of heroin, some decrease of cocaine, and a slight increase of morphine. No less than 34,279 kg. of morphine were however required for "conversion," chiefly for the manufacture of codeine, of which 25,710 kg. are estimated as the world requirement for 1936. The increasing demand for morphine for "conversion" has attracted the attention of the Supervisory Body and is being carefully investigated. For 59 countries and 89 territories the estimates were furnished by the Governments concerned; in 11 countries and 9 territories the Supervisory Board, in default of such returns, had itself to frame them. In tables appended to the report are set out for each narcotic drug the estimated requirements of each country and territory for the year 1936. The compilation of this elaborate return (C. 429. M. 220. 1935. XI.) reflects great credit on the Supervisory Body and the secretariat of the League.

THE COMPOSITION OF "WHITE BILE"

A GROUP of workers engaged on a study of gall-bladder function¹ have been fortunate in obtaining 15 examples of "hydrops" of the gall-bladder from patients in whom the cystic duct was obstructed. In their opinion the sequence of events in these cases is: damage to the biliary system; obstruction of the entrance of bile into the damaged gall-bladder; dilution of the gall-bladder contents; and finally decoloration of the bile by absorption or destruction of the pigment. Whether acute infection plays a part they have not decided. The colourless contents of the gall-bladder are secreted by its damaged mucosal cells, bile salts and bile-pigment being absent. In this white bile chlorides and calcium are found at approximately serum level though sometimes (in 5 of the 15 cases) the calcium content is considerably higher. The amount of cholesterol varies: in 9 cases it was either absent or present in proportions under 9 mg. per 100 c.cm., while in the other 6 the figures ranged from 15 to 143 mg. per 100 c.cm., the higher cholesterol figures being usually associated with a higher calcium content. There is as yet no obvious explanation for these facts. In 2 cases in which the gall-bladder was drained, daily observations were made of the composition of the fluid obtained. Bile salts did not reappear within the period of study, presumably because the cystic duct remained blocked. The chlorides remained at the usual level of 90–120 milli-equivalents per litre. The calcium figures were very constant; in one case they showed a slight gradual decrease, but they were always approximately at serum level.

¹ Ricgel, C., Raydin, I. S., Johnston, C. G., and Morrison, P. J.: *Amer. Jour. Med. Sci.*, November, 1935, p. 653.

The cholesterol content was much higher in one case than in the other. It is hoped by these investigations of the isolated gall-bladder and ducts to get information about the functions of these structures. Unfortunately, in the human subject their isolation is often due to a preliminary inflammatory process which somewhat vitiates the experiment.

THE MARCH OF MEDICINE

THE turn of the year is the traditional time for reviewing the year's events and achievements. The few days that come after the festivities of Christmas and before the New Year's invitation to good resolutions, should be made to yield an hour or two for detached retrospection, not sentimental, but rather a little critical. Those who have, or aspire to have, a hand in the advancement of medicine, whether by making discoveries, by proclaiming them to the world, or by applying them for the benefit of the sick, may well take the Year Book of General Medicine¹ as the basis for their retrospective meditation. The 1935 volume actually deals with work published between mid-1934 and mid-1935, and can therefore be in our hands before Christmas. It is edited by six physicians of great eminence, who have chosen for abstraction the most valuable papers in their several fields, and have often added for the reader's great benefit their own brief comments. In the period they cover there has been no single discovery of startling importance, but the march of medicine on many fronts has been steady and progressive. The impetus given to hæmatology by Minot and Castle has not spent itself, but is spreading rather to adjacent subjects; in their section of the book they call special attention to a report of the production in pigs, through a vitamin-deficient diet, of changes in the oral and gastric mucous membranes, achlorhydria, diarrhoea, muscular weakness, and macrocytic anæmia—a picture so like that of pernicious anæmia that it may be a clue to the causation of that disease and perhaps also of some of the chronic "gastric" conditions towards which a great deal of interest has lately been directed. In the gastrointestinal section there are several important papers on chronic gastritis, which is now satisfactorily defined in terms of structural changes in the gastric mucosa, although its relation to functional changes and to symptoms, as well as its pathogenesis, remain obscure. Meulengracht's localisation of the source of the intrinsic (gastric) factor of the anti-pernicious anæmia principle is another notable advance in this field; medicine is undoubtedly marching, in Napoleonic fashion, on its stomach.

Three other sections, on cardiovascular disease, on lung disease, and on infections, complete the book, for "General Medicine" is defined by exclusion, and endocrinology, neurology, psychiatry, and therapeutics find their places in others of the Year Book series. In cardiology, many writers seem to be re-working old ground, often with greater care and more precision than heretofore; the bold attempt to ameliorate cardiac failure and severe angina by total thyroidectomy is being continued, and "this rather radical procedure still seems definitely indicated in a number of carefully selected cases." Among the infectious diseases, the virus investigators are working quietly ahead. In the chest section, the

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXII.—PROGNOSIS IN TUBERCULOUS INFECTIONS OF THE SKIN

Of the tuberculous diseases those affecting the skin are, for a variety of reasons, among the most interesting and complex. Their development and course can be observed by the unaided eye, and their accessibility affords wide scope for therapeutic measures, which are moreover easier to control and adjust than those designed to cure organs or tissues within the body.

With a single exception—the primary tuberculous chancre—every form of cutaneous tuberculosis is associated with a similar infection of the lungs, glands, bones, or internal organs, and it is essential to make a careful search for a primary focus as soon as the nature of the skin lesion has been established. Neglect to do this, besides affecting the prognosis, may lead to disaster. I have twice seen hæmoptysis—the first recorded in the patient's history—follow within a week the application of general carbon arc baths in the treatment of lupus verrucosus, and it is not without significance that, as is well known, Dr. Rollier will not accept at Leysin cases of bone or joint tuberculosis complicated by active pulmonary tuberculosis. This interplay of cutaneous and visceral tuberculosis, which involves the vital factor of the degree of immunity, is undoubtedly the chief consideration in achieving anything like a correct prognosis, as far as the skin lesion is concerned. A detailed discussion of all that is here implied by the term immunity is beyond the scope of this article, but for the proper comprehension of the factors on which the course and prognosis of any given tuberculous infection of the skin can be estimated, some consideration of it is essential. Immunity may be regarded from two points of view, as far as the skin is concerned: (a) the type and virulence of the infecting organism, and (b) the reactions of the individual as a whole, and the infected tissue in particular, to the invading bacillus. Prognosis is thus a highly complex problem, depending, first, on the three variables indicated in (a) and (b), and secondly on the patient's environment, the standard of treatment available for him, and his ability to attend regularly for its controlled application.

Lupus Vulgaris and Lupus Verrucosus

Lupus vulgaris is by far the commonest as well as the most disfiguring and disabling form of cutaneous tuberculosis. It varies very greatly in its virulence and response to treatment, and the prognosis must vary accordingly. It would be greatly improved if all the patients affected could be admitted as in-patients to an establishment equipped (as few are) with a highly trained staff and all the modern technical apparatus required. At the Finsen Institute at Copenhagen S. Lomholt (1934) claims to achieve a cure in 80 per cent. of cases. It is probable that this figure could not be approached under existing conditions in this or any other country at the present time, and in most out-patient clinics 50 per cent. of cures would be regarded as an enviable result. The gloomy outlook could of course be improved if diagnosis and correct treatment were established at an early stage. It is possible and may be advisable to excise the early patch of lupus, and most of the cases in which this is done efficiently do not relapse. On the other hand, it is difficult even to alleviate

the condition when once the mutilating and destructive process has involved the nose and ears, and perhaps the cheeks, lips, and eyelids as well. Lomholt emphasises the importance of attacking all lesions at once and over the greatest possible area, with rapidly ensuing courses of Finsen and carbon arc light. Every authority will agree with this assertion and also with his view that X ray therapy should be entirely abandoned in lupus treatment partly because of the risk of subsequent "X ray" carcinoma, and because skin so treated loses its vitality in some degree and fails to respond subsequently in the normal way to ultra-violet rays whether natural as from the sun, or artificially produced as in the Finsen lamp. The age of the patient is another if less important factor in prognosis. Lupus seldom begins after the age of 35 or 40, and when it appears then is relatively benign and easier to eradicate. Over 80 per cent. of its victims are attacked before the twentieth year, and such young persons not infrequently suffer from associated tuberculous disease of the glands, joints, or bones, although pulmonary tuberculosis is rarely present. It has already been emphasised that with one rare exception, all T.B. of the skin is associated with latent or active infection elsewhere, and with this fact in mind every effort should be made to improve the general resistance by appropriate diet (Hermannsdorfer-Gerson salt-free diet and cooking), and by a change, where this is possible, to a dry and sunny climate. By far the best for this purpose, judging by results, is that of the high Alps, where the most inveterate forms of cutaneous lupus and other tuberculous infections usually respond within the year to the unaided effects of solar light.

Two severe cases of facial lupus in hospital patients sent by me some five years ago returned after 14 and 11 months with perfectly healed soft cicatrices, and have not subsequently relapsed. Both patients attend regularly for supervision, but are able to follow their ordinary vocations—the man as an optical lens grinder, the woman as a housekeeper. No other method of treatment known to me can be relied upon to offer such good chances for the future, and it is my confident opinion that the permanence of the cure results from the treatment of the patient rather than of his lesion, for this is actually protected from the direct rays of the sun during the daily exposures of the rest of the body. A third case of facial lupus—a young man whose early patch on the cheek had relapsed after surgical removal in childhood, and had then failed to respond to repeated X ray treatment—was not so fortunate, and Dr. Rollier wrote explaining that the skin had been too seriously devitalised by X rays to give the usual response in the area affected.

Previous treatment by X rays is thus a factor to be considered seriously in estimating prognosis as far as lupus is concerned. Authoritative opinion is gathering strength against its use both in lupus vulgaris and lupus verrucosus, in which the temptation to apply it is greater because of the warty character of the tuberculous infiltrations. This feature tends to chronicity, and while doubtless it is part of a defence mechanism, it renders even more difficult the extirpation of the invading bacilli, which must be the ultimate aim of every therapeutic measure. Prognosis therefore in a case of the verrucose variety of the disease must be guarded in the extreme, for relapses after apparent cure are the rule rather than the exception.

In estimating the future in these two varieties of

SPECIAL ARTICLES

AN IMPROVED TECHNIQUE FOR
ADMINISTERING INTRAVENOUS
SOLUTIONS AND FOR BLOOD
TRANSFUSION

By J. E. MCCARTNEY, M.D., D.Sc.

DIRECTOR OF RESEARCH AND PATHOLOGICAL SERVICES,
LONDON COUNTY COUNCIL.*(From the Southern Group Laboratory, Park Hospital,
London, S.E.13)*

THE use of various solutions for intravenous injection has much increased of recent years. The value of saline solution in shock, gum anæmia in hæmorrhage, and glucose in toxic exhaustive conditions is being more and more recognised.

In emergencies it is necessary to have a supply of reliable material ready to hand, which can be administered intravenously with little or no trouble in preparation. The following method has been introduced for use in the London County Council hospital service. The advantages are that adequate supplies of material can be kept always available and that the administration of intravenous solutions is considerably simplified and free from contamination.

Supply of Intravenous Solutions

The central supply and distribution of material for intravenous use for the Council's hospitals is undertaken at the Southern Group Laboratory, employing the "canned media" principle already introduced and developed for culture media.¹ All solutions are put up in white flint screw-capped bottles. The cap, furnished with a rubber washer, is tightly screwed on, and the bottles containing the fluid are autoclaved. In this way the solution is "canned." As the bottle is hermetically sealed the fluid cannot evaporate, neither can it become contaminated. In order to ensure that the bottle has not previously been opened the top is covered by a Viskap, while identification of the contents is ensured by coloured beads, labels, and caps. Even when the cap is removed and the labels have become detached through immersion in warm water, the beads still act as an indicator of the contents.

The various fluids available are: normal saline; Ringer solution; glucose (in saline or Ringer solution) in strengths of 5, 10, 25, and 50 per cent.; sodium citrate 3.8 per cent.; gum anæmia 6 per cent. in saline; and distilled water. The last is used for making hypodermic solutions and for dissolving arsenamine, &c.

CONTAINERS

In order to avoid a multiplicity of containers, the following screw-capped bottles are standardised * :—

10 oz. round Winchester series, holding 1000 c.cm.	A
20 oz. " " " " " " " " " " " "	500 c.cm.
12 oz. medical flats, holding 250 c.cm.	
6 oz. " " " " " " " " " " " "	100 c.cm.
4 oz. " " " " " " " " " " " "	60 c.cm.
10 c.cm. ampoules.	

* These have same size of cap.

The bottles are received from the makers already washed and clean. They are immersed in distilled water and then autoclaved with the distilled water

in them, which effectively sterilises them and removes alkalinity from the glass.

The fluid is made up in batches of 4 litres or multiples thereof, and filtered through a glass filter into the containers. The appropriate coloured beads are added to the bottles. The caps are screwed on tightly, and the bottles are autoclaved at 15 lb. pressure for twenty minutes. They are removed from the autoclave and when cooled the viskaps are put on. When dry the viskaps are painted the appropriate colour (with cellulose paint) and the labels attached to the bottle. Ampoules are made of B.P. neutral glass and are the same as used for the Council's diphtheria and scarlet fever antitoxin. With ampoules, beads are not practicable; instead, after sterilisation the ampoules are painted on the bottom with cellulose paint.

The colour scheme used for beads and labels is as follows:—

Saline	Dark blue.	Sodium citrate	Red.
Ringer	Black.	plus another bead to indicate strength, thus:	
Glucose	Green.	Red and white	3.8%
plus another colour to indicate strength, thus:		Red and red	20%
Green and white	5%	(2 red beads)	
Green and brown	10%	Gum saline	Brown.
Green and yellow	25%	Distilled water	White.
Green and green	50%		
(2 green beads)			

When any of the above solutions are made with Ringer solution, an additional black bead is added, and a black ring is painted round the viskap. Those made with normal saline have a blue bead.

The 50 per cent. glucose in 60 c.cm. amounts is used in diphtheria and other acute toxic conditions, while the 5 per cent. solution of glucose in Ringer solution is an improved substitute for saline.

Administration of Fluids

The following method of administering fluid direct from the bottle simplifies the procedure and avoids contamination. Screw-capped bottles have previously been adapted for filtering,² or the collection of blood for adult measles serum,³ and the same method has been extended to intravenous injections. The method is readily understood by reference to Fig. 1.

APPARATUS REQUIRED

- Intravenous solution in screw-capped bottle.
- Metal screw-fitting for bottle, brass, chromium plated.
- Metal carrier to hold bottle, brass wire, tinned.
- Three pieces of rubber tubing of 5 mm. bore: (1) To reach to bottom of bottle (p). This should be tied with figure silk to the metal fitting at (n) and the free end should be notched as sketch. (2) Small piece (r) 2 in. long, attached to the side-arm (c). (3) A long piece (s) attached to the bent arm of the fitting (at A) furnished with a bubble trap (u), a clamp (j), and an adaptor (k) for the needle.

(e) Sterile air filter (a). This consists of a piece of 5 mm. glass tubing containing cotton-wool and drawn to a point at each end.

(f) Ampoule file.

(g) Rubber blow-ball.

Three sizes of metal fittings are used, viz. :—

Large size	} to fit bottles holding	500 c.cm. and 1000 c.cm.
Medium size		250 c.cm.
Small size		50 c.cm. and 100 c.cm.

These amounts are stamped on the fitting. The metal carriers for the bottles are designed so that the rings indicate the amount of fluid taken from the bottle. The amounts are stamped on the carriers.

* These are manufactured by the United Glass Bottle Manufacturers, Ltd., 10, Norfolk-street, London, W.C.2.

METHOD

Place the bottle of intravenous fluid in the appropriate holder, and immerse in warm water. The metal fitting, with rubber tubing, bubble trap, clamp, and adaptor properly attached, is sterilised by boiling, or may be wrapped in Kraft paper and sterilised in the autoclave. Remove the viskap, unscrew the cap from the bottle, insert the rubber tube (D), and screw on the metal fitting. File and break off the pointed ends of the air filter (G), and insert one end into the rubber tubing (E). Attach the blow-ball to the free end of the air filter (G). Hold the tube (F)

FIG. 1

Apparatus for administering fluids intravenously.

vertical, release the clamp (J), blow air into the bottle until fluid issues from the adaptor (K), close the clamp, lower the tube (F), and remove the blow-ball.

The fluid is now ready for administration, and during the injection siphons over from the bottle. The carrier may be suspended by hooks to a pulley arrangement so that the height can be varied, or it may be hung on a hook on the wall. The pressure of fluid depends on the height of the bottle above the patient. Alternatively, the bottle may be kept at the bedside and the necessary pressure obtained from the blow-ball, which in this case is not detached from the air filter.

Blood Transfusion

The blood is withdrawn by suction into a screw-capped bottle containing sodium citrate solution to prevent clotting. When the required amount of blood has been obtained it is administered intravenously as above described.

APPARATUS FOR WITHDRAWING BLOOD

(a) 40 oz. round screw-capped. Winchester series bottle containing 75 c.cm. of 3.8 per cent. sodium citrate in Ringer solution, prepared and sterilised as the intravenous solutions previously mentioned.

(b) Screw-cap fitting as for intravenous injection, but fitted as Fig. 2. To the bent arm is attached a short piece of rubber tubing (B) fitted with an adaptor and wide bore needle. This type of apparatus has been used with success in withdrawing blood for adult measles serum.³

(c) Gauge (M) for estimating amount of blood consisting of a flat piece of brass, chromium plated, 6 in. long, $\frac{1}{4}$ in. wide, and $\frac{1}{16}$ th in. thick, marked to indicate 100 c.cm. amounts in the bottle.

(d) Air filter (G).

(e) Piece of rubber tubing (F), 18 in. long, with glass mouth-piece.

(f) Two rubber bands (R) $\frac{1}{2}$ in. wide.

APPARATUS FOR ADMINISTERING BLOOD

(a) Screw-cap fitted as in Fig. 1.

(b) Sterile air filter.

METHOD

The rubber tubing (B), Fig. 2, adaptor, and needle are lined with liquid paraffin, and attached to the bent arm (A) of the screw-fitting. The short piece of rubber tubing (E) is attached to the side-arm. These are then wrapped in kraft paper and autoclaved.

When blood is to be withdrawn, the bottle and contents are warmed, and the gauge (M) fixed to the bottle with the rubber bands (R) so that the zero mark is level with the surface of the citrate solution. The cap of the bottle is now removed and the screw-fitting applied. The tips of the air filter are filed and broken off. One end is inserted into the tube (E) and the other into the long tubing (F) (Fig. 2) carrying a mouth-piece.

The needle is inserted into the vein of the donor, and gentle suction applied to the mouth-piece with the mouth. Blood is seen pouring from the lower part of tube (A) into the bottle and its rate of flow observed. While the blood is pouring in, the bottle is gently rotated to mix the contents, while the actual amount obtained is read directly on the gauge. When enough blood has been obtained, and the needle withdrawn, the gauge and rubber bands are removed, the bottle is fitted into the wire carrier

FIG. 2

Apparatus for obtaining blood for blood transfusion.

as in Fig. 1, and placed in warm water. The blood is not administered to the patient with the same screw cap through which it was withdrawn.

The screw-fitting as in Fig. 2 is removed, and the screw-fitting as in Fig. 1, with rubber tubing attached and already sterilised, is substituted. The blood is administered to the patient as though it were the intravenous solutions previously described.

The above methods have been extensively used in the London County Council's hospitals during the past year, and their usefulness and convenience amply demonstrated.

PLAGUE IN AFRICA

Nor the least valuable of the activities which the Office International d'Hygiène publique maintains is that of publishing at suitable intervals reviews of the epidemiological history and present position of the great plagues which afflict mankind—cholera, yellow fever, pandemic influenza, and the plague of plagues, the Black Death or *pestis major*. During the years 1924-27 the Office collected and, in 1928, it published, in a volume supplementary to its *Bulletin*, the information it had collected on rodents and fleas as the harbourers and transmitters of plague. The volume was prefaced by a general review by Prof. Ricardo Jorge, the Portuguese delegate to the Office and the greatest living authority on historical loimology.

In 1932, at the Capetown conference presided over by Sir George Buchanan, president of the Office, it was decided that an inquiry should be made on plague in Africa, its peculiarities as to spread, its tendencies to increase or diminish, the part played by animal carriers, and the prophylactic measures against it. Now there has appeared a general report, again by Prof. Jorge,¹ dealing with the material collected.

ROUTES OF INFECTION

In his first chapter he sketches the last flickerings of the ancient "Mediterranean" plague which had lasted for untold centuries and given rise at frequent intervals to epidemic waves, spreading from the Mediterranean basin north, east, and west, with consequences writ large in European history. He notes that, in contrast, its extension south was never great. Egypt, Tunisia, Algeria, and Morocco shared with European countries successive outbreaks throughout the centuries while the rest of Africa remained free, though from the fifteenth century onwards plague-infected ships were sailing round the Cape and calling at the ports of both eastern and western coasts. By the end of the seventeenth century plague in Europe was dwindling; it may be said to have ended with the epidemics in Marseilles (1720) and in Messina (1743). In North Africa it lingered for another hundred years: Egypt, especially, suffered from frequent outbreaks, with as many as 200,000 deaths, for example, in 1835, and not until 1844 was Egyptian plague completely at an end. Morocco (1818), Tunisia (1822), and Algeria (1822) became free a little sooner. For the fifty-five years from 1844 to 1899 North Africa was free from epidemic plague. In Uganda, Kenya, and Tanganyika plague was undoubtedly endemic, though not epidemic, in the last quarter of the nineteenth century and was observed by Robert Koch himself during his visit to German East Africa in 1897. Jorge regards this East African plague as possibly the last remnant of the ancient "Mediterranean *pestis*," and thinks that there was a brief interval, from 1899 to 1902, during which East Africa was free, to be invaded once more by the "contemporary pandemic" which took origin in China. An alternative view of great interest, learnedly maintained by Dr. Isgaer Roberts,² is that the eastern portion of Central Africa is one of the natural homes of plague, that this endemic was carried during all the ages by negro slave traffic across the Red Sea to Asia and thence to Europe, and that no importation hypothesis is required for

its twentieth century prevalence in Uganda and the surrounding territories. There is, in any case, no doubt that in 1899-1900 Africa was again invaded from north, south, east, and west by the great contemporary pandemic; Alexandria, Philippeville (Algeria), Mombasa, Mozambique, Capetown, Grand Bassam (Ivory Coast), Senegal, and Lagos all acted as ports of entry in turn, though the precise dates cannot always be established, and the actual source of introduction of the infection is accordingly in doubt. For each of these ports and the adjacent territory Prof. Jorge gives detailed statistics and a graphic account of the incidence of plague during the present century. It is probable, however, that for Egypt and eastern ports the origin was Asiatic, for the Cape it was almost certainly South American (Argentina and Paraguay), while for Algeria and Tunisia sea-borne traffic through Marseilles may be suspected.

Often this sea-borne infection has displayed low powers of penetration. Cases of plague occurred from time to time in the ports and the disease survived as an *enzoötic* among the local rats without spread to the hinterland. There are, on the other hand, some striking exceptions in which the incidence of plague in the ports has remained low but the disease has become established in the interior served by them. This "sylvatic plague" has developed in Morocco, in Upper Egypt, in Uganda, Kenya, and Tanganyika, and, especially, in the Union of South Africa. In South Africa the ports have been free from plague for the last twenty years, but the back-country veld is a typical example of sylvatic plague, characterised by its *enzoötic* existence among the wild rodents. This sylvatic plague and, in fact, plague throughout Africa, except in Uganda and its neighbours, has in recent years had a very low incidence on the human population. It is indeed very remarkable that the same disease that in Asia has slain its millions since the century began should spare, as it has, the African native. For it seems fairly clear that, taking Africa as a whole, plague is disappearing, partly as the result of prophylactic sanitation in the ports and partly by spontaneous regression, the mechanism of which can be the subject only of speculation.

ANIMAL VECTORS

The second half of the review dealing mainly with the animal vectors—rodents and their fleas—is full of epidemiological interest but cannot be summarised, since each area differs in the prevailing species of its rodents and in the habits of its human population in respect of contact with them. The cycle rodent-flea-man has proof after proof heaped upon it in the course of Prof. Jorge's survey, though the cycle man-flea-man is not neglected, since it is in Africa, more than anywhere else, that this type of conveyance is most convincingly displayed (Morocco, Algeria, and Tunis). Among the many curious observations on the dependence of plague on animal hosts, one of the reasons put forward for the remarkable modern immunity of Cairo may be selected as an example. Though rats, both grey and brown, persist in the city (harbouring plentiful *Xenopsylla cheopsis*, the plague flea par excellence), yet they are never numerous, being kept down by the African weasel (*Mustela africana*) which flourishes in the native quarter and prevents the rat aggregation necessary for a plague epizootic to occur.

The last two chapters deal with clinical varieties of human plague in Africa, with the relation of these to climatic and racial differences and finally with the

¹ Suppl. to Bull. mens. de l'Office Internat. d'Hyg. publ., 1935, xxvii., 67.

² East Africa Med. Jour., 1935, xi., 200.

defensive measures now in force. On all these interesting observations are offered, some illustrating the laws which plague obeys in Africa as elsewhere, while others, not the least instructive, are peculiar to the African scene.

PUBLIC MEDICAL SERVICES

A REPRESENTATIVE CONFERENCE

A CONFERENCE of representatives of public medical services was held at B.M.A. House on Dec. 19th in pursuance of a resolution passed by the annual representative meeting last July. Dr. E. KATE LE FLEMING occupied the chair.

The primary bases of the conference were: (1) the B.M.A. model scheme for a public medical service; (2) an explanatory memorandum on the scheme; (3) a confidential report on the work and conditions of existing services. Their reception was followed by a statement from Dr. G. C. ANDERSON (medical secretary, B.M.A.), who hoped that the conference would be an annual affair. He outlined the history of the public medical services, mentioning the spread of the idea after the war, beginning with Essex. He said that adequate medical attention for the poorer and working classes involved some form of insurance. There was a tendency throughout the country for contract schemes to start afresh, and to start in a manner detrimental to the profession. The way to stop that was to start in the area a public medical service based on the B.M.A. model. The trouble was apathy; the doctors failed to see the writing on the wall. Probably the income limit would have to be raised before long; and ultimately consultant and specialist benefit would have to be included. Transfer of benefits between schemes should be arranged. The wage-earner was accustomed to make a weekly budget; why should he not be able to include in it provision for medical attendance on his dependants? There was nothing degrading in contract practice, and if the B.M.A. did not arrange it, someone else would.

Dr. ALFRED COX, representing the London Public Medical Service, read a paper on public medical services and

Encroachments on Private Practice

The P.M.S. idea, he said, meant something far more constructive than a mechanism for collecting money. A doctor's bill might be a very real terror in the working-class home, and the wage-earner might be forgiven if he hesitated to call in the doctor and put up with a medical service far below the ideal. The object of a P.M.S. was to provide for such people a family doctor and medical service which fulfilled modern ideas of what was desirable. Most of the encroachments on private practice of which complaints were made were due to the desire of the local authority to give medical services which the family doctor was not providing. Once established, however, clinics—like hospital out-patient departments—were abused. In areas where there was no P.M.S. the profession could never give a valid answer to these encroachments. The public must be convinced that the doctors were willing and able to do the work, and local authorities must be shown that much public money could be saved. At present no P.M.S. could claim to do the work done by the authorities as well as it was now being done, but the difficulties were not insuperable. The first necessity was a well-organised and popular service providing all the benefits through

some or other of its members. There must be one family doctor responsible; there was no logical defence for the present system whereby a municipal doctor took charge for a brief period of the patient's life and then disappeared altogether. Continuity was the trump card of the family doctor. Everyone admitted its desirability in theory. Much leeway had to be made up. The individual practitioner could never compete with the organised Government service, but a P.M.S. could do so. It was no use simply grumbling about encroachments; the profession must show that it had learned its lesson. The doctors must be proud of their contract and make it better even than private practice.

Dr. A. MCCARTHY (Birmingham) pointed out that an established P.M.S. could demand representation on all public bodies, and then could nip future encroachments in the bud. Legally, a P.M.S. must be regarded as a collecting agency if the expense and complication of forming a company were to be avoided, but that did not prevent the members from remembering and following their ideal.

Dr. COX reiterated his view that so long as the profession regarded a P.M.S. as a means of collecting money it would do nothing to prevent encroachments, but would rather have to meet further encroachments.

Dr. S. WAND (Birmingham) spoke on the

Necessity for Publicity or Advertisement

For the first time, he said, the B.M.A. had laid the word "advertisement" before the profession without explanation, qualification, or apology, and that was very important. The objects of publicity were to bring to the notice of everybody—employers and employees—the value of the P.M.S. and to make the public trust it. To get at those who did not attend doctors' surgeries Birmingham had an "all or none" rule insisting that families must join and leave en bloc and never as individual members. An energetic subcommittee was the first requirement. The doctors were made keen by showing them the objects of the P.M.S. and by encouraging social intercourse and mutual trust. Recruiting letters could be sent out with the cheques. Birmingham had devised the slogan that every member should aim at getting one new unit a day. The most important item of all in advertisement was the service rendered by the doctor; doctors could also help by giving out leaflets, displaying notices, and explaining to patients. Another valuable slogan was: "Get at the women!" It was the wife who usually had to pay the doctor's bill. Newspapers could be interested in several ways; interviews were worth far more than entries in the advertisement columns. A notice thrown on the screen at the local cinema had proved valuable in backward areas. Slips could be put in panel medical cards, and leaflets distributed in hospitals, clinics, factory social services, and local health committees. Small booklets had proved of great value in Birmingham. Withdrawals were being followed up and analysed, but were not regarded as very serious. Four axioms for publicity were:—

(1) Lay publicity must not be expected to produce rapid increases but had great value in educating the public and preparing them for the attack of the doctor himself. This was predisposing publicity.

(2) Exciting publicity was the doctor himself.

(3) Results did not just happen; they were only achieved by hard work.

(4) Get at the women.

Dr. JOHN YOUNG (Edinburgh) asked if the hospitals had given any undertaking not to take casual out-

patients. Other members asked questions bearing on the acceptability of the advertising methods outlined.—Dr. R. S. MARSHALL and Dr. J. WELLS (Wolverhampton) stressed the importance of the service rendered and the difficulties produced by half-hearted members. Dr. Wells suggested a panel of doctors to teach girls home nursing, so that the services of a nurse might be available to members of the P.M.S.—Dr. A. N. MATHIAS said that London had tried all ways of advertising and had concluded that the only worth-while method was to satisfy the patient.—Dr. G. IRVING said that that was the only method used by Stockton, which had done very well. Birmingham had 32,000 units and the much smaller Stockton had 6265.—Dr. E. LEWIS LILLEY described a successful collaboration with nurses in Leicester.—Dr. C. H. PANTING (Leytonstone) said that Essex never had advertised and did not intend to. The first essential, said Dr. A. K. GIBSON, was a first-class service.

Dr. WAND, in reply, agreed that the important publicity was the doctor, through the services he gave. Lay publicity was only used for a certain type of patient who did not at present attend a doctor's surgery—possibly because of the counter-attractions of free clinics. The total cost of publicity in Birmingham had been less than £110.

Dr. PANTING opened the afternoon session with a paper on

The Business Aspects

of public medical services. The new service, he said, was going to be a business. Policy would be considered with less anxiety. Instead of taking up much time with its discussion, a scheme should be adopted which had proved workable and only amended if local conditions definitely demanded it. In Essex great savings had been effected, especially in stationery, by the collection of sufficient capital. The committee had borrowed £220 from the doctors and £400 from the National Defence Trust, and this had all been repaid in six years. It was prudent not to rely on any profits during the first two years. The office could not be run on a 5 per cent. basis. Many services were handicapped at the start by not appointing a capable whole-time secretary. Collecting was skilled work and the collector must, besides being honest, be resourceful and tactful. Past members of friendly society staffs were perhaps the best. Salary should increase with the amount of work done, with no limit. To retain subscribers it was necessary to curb the activities of doctors who accepted patients without fully explaining to them the implications of the scheme. No arrears should be tolerated, and then the service would be held in respect. Other factors in efficient working were the provision and arrangement of doctors' and collectors' ledgers, the method of recording names and details of every book in use, and that of presenting doctors every quarter with lists of their subscribers.

Dr. W. DABBS (Coventry) explained details of the scheme which had been administered in his district for 40 years.—Dr. MCCARTHY said that men were better whole-time and women better part-time collectors.—Dr. COX advised that collectors should treat trivial complaints by tact, but make the patient submit serious complaints in writing to the committee.—Dr. LILLEY (Leicester) said that fees must vary with the economics of the area. Services which provided dispensaries, grants, and special benefits must change correspondingly more.—Dr. S. A. FORBES (Croydon) described a local scheme whereby chemists did the collecting, getting a 2½ per cent.

commission, and Dr. J. J. DAY said that Kent had a similar arrangement.—Dr. JOHN STEVENSON (Ayr) said that their clerk was paid on a 5 per cent. basis and was not dissatisfied.

Resolutions

The rest of the day was occupied by a number of motions sent up by various districts. Dr. Alfred Cox was unanimously elected chairman of next year's conference and then took the chair.

Essex asked the Association to issue a pamphlet dealing with the business side of public medical services, but Dr. ANDERSON thought it was too soon for a stereotyped pamphlet and persuaded Dr. PANTING to withdraw his motion.

Stockton (through Dr. G. IRVING) asked the B.M.A. to prepare scales of minimum rates so that the capitation fee should be kept up to a minimum level.—Dr. A. K. TOWERS supported Stockton's motion, withdrawing a similar one by Wallsend. In the distressed Tyneside area, he said, rates based on 6d. a week for the first adult were being paid. Such a rate should, he thought, be standardised all over the country.—Several members felt that the time was not ripe for standardisation and that at present areas must fix their own rates under some kind of control from the central office; they also feared lest a standard minimum rate should become a maximum.—Dr. GIBSON argued that the bulk of the working population was able to pay for what it wanted and it was no part of the policy of depressed areas to make depressed doctors in them. He supported the Stockton resolution, but Dr. WAND, for the same reasons, opposed it.—Dr. C. HILL (deputy medical secretary, B.M.A.) pointed out that the capitation fee did not bear a direct relation to the subscription. A high weekly rate might mean a low remuneration because it did not attract enough members. After further discussion, evidencing some fear that any fixed rate might in the future be held up against the profession, the motion was lost by a large majority.

Dr. J. L. O'FLYN (for Barry) then suggested a reduced rate for the unemployed.—Dr. F. W. GRANT (Jarrow) said that 70 per cent. of his patients were unemployed and he knew of no demand for lower rates.—Dr. W. A. KERR (Swansea) said that temporary unemployment made the position difficult.—Dr. H. F. WATTSFORD (Newcastle) characterised the motion as dangerous and unnecessary. After further opposition on the same lines, the motion was lost by a very large majority.

Barry also wished to raise the income limit to £300, but Dr. WAND pointed out that this had been passed—as a local option—by the representative body and the motion was withdrawn.

Dr. TOWERS proposed for Wallsend that the following additions be made to the list of benefits not included in a P.M.S. in the Association's scheme:—

Miscarriages, inoculations, treatment by injection, specialist treatments (oculist and aurist).

Cod-liver oil, linseed meal, serum (unless supplied by the public authority), insulin and other medicaments used for injection, oxygen, vaccines, and bacteriological examinations.

After the argument had swayed in both directions Dr. ANDERSON pointed out that the B.M.A. scheme was only a model, subject to local option, and deprecated the inclusion of a long list of specific exceptions.—Prof. R. M. F. PICKEN secured the approval of the meeting when he said that the resolution required a great deal more thought, and a small majority voted against it.

Later the meeting considered three motions by London:—

That the conference is of opinion that there should be some mutual arrangement amongst public medical services for dealing with subscribers to services who are temporarily resident in areas other than the one in which they are subscribers.

That the machinery of the B.M.A. ought to be used, in those areas where approved public medical services are operating, in order to minimise the offer by municipal and voluntary authorities of medical services which the general practitioner can render, and which it is the object of public medical services to make available.

That in the opinion of the conference there should be a public medical service committee of the B.M.A. fully representative of public medical services, on lines analogous to those of the Insurance Acts Committee.

The first of these was left to the future committee to consider; the second was passed; and the third was left as a recommendation to council.

Finally, it was decided that conferences of this kind should be held annually.

MEDICINE AND THE LAW

The Question of Assessors

ON Dec. 13th a London evening newspaper reported that a coroner had called in the treasurer of the London Football Association to assist him at an inquest on a man who died from injuries received while playing football. The evidence showed that the game was being fairly played and that the injury was accidental; the verdict was returned accordingly. One does not think as a rule of a coroner sitting with an assessor except in the statutory cases of accident inquiries—e.g., under the railway legislation of 1871 which enabled the coroner to apply to the Board of Trade, now the Minister of Transport, for the services of an expert.

On the same day, as it happened, Lord Dawson of Penn, speaking at the annual dinner of the Medico-Legal Society, referred to the possibility of placing scientific and medical men as assessors on the Bench where a court had to deal with the complex problems of crime, the prevention of crime, and the close association of crime with disease. The Court of Admiralty does not disdain the assistance of nautical assessors; why should the law be afraid of medical help in medical problems? The answer presumably would be that the law fears that the criminal will escape trial or conviction if the doctors have their say. Once the accused has been found guilty, the administration of justice is content that the sentence should be commuted on medical grounds which a judge would probably have rejected during the trial.

A Doctor's Experiences as a Company Director

A doctor of medicine has given his name to a leading case on a curious point of company law. In 1932 Prof. J. W. H. Eyre, M.D., formerly director of the bacteriological department at Guy's Hospital, was invited to join the board of directors of Milton Proprietary Ltd., a company which manufactures a disinfectant preparation. The company's articles of association prescribed that one-third of the directors should retire annually but should be eligible for re-election; the directors to retire should be those who had been longest in office; where two or more had served for an equal period, the retirement should be "decided by ballot." These innocent words were ambiguous. Did they mean "decided by lot" or "decided by a secret vote of the directors"?

When it was necessary lately to determine which directors should retire, there was one with the longest service who would therefore be the first to retire, and there were two others of equal length of service of whom one must be selected for retirement. These two were the chairman and Prof. Eyre. At a board meeting in November the chairman asked Prof. Eyre to sign and hand in his resignation; the request was refused. At a subsequent board meeting the question was put to the vote; Prof. Eyre and two other directors refused to vote; the remaining directors voted that the professor should retire. He then brought an action claiming a declaration that determination by ballot meant by drawing of lots and that the decision by a majority vote was illegal. Analogies were sought from the old Militia Act and other statutes. Mr. Justice Eve thought the articles intended to confine the decision to the directors and that "ballot" must mean a secret vote. The Court of Appeal last week upset the court below. The Master of the Rolls, agreeing that the words might be interpreted either way, found that the word "ballot" was used in the Companies Act of 1862 but that "lot" had been used in subsequent enactments. The language and the practical considerations (since there was no provision for a casting vote) led him to conclude that "ballot" in the defendant company's articles meant "lot." A further point of construction settled the matter temporarily in Prof. Eyre's favour in any event. In calculating the total number of directors, "additional directors" (appointed to hold office till the next general meeting) were to be disregarded. It resulted that only one director had to retire this month and thus neither the chairman nor Prof. Eyre need do so.

AGRANULOCYTOSIS AND AMIDOPYRIN

CORONER AND THE POISONS BOARD

ON Dec. 20th Dr. Bentley Purchase, coroner for St. Pancras, sitting without a jury, concluded his inquest on the body of a woman of 60 who died on Dec. 10th. The first hearing, on the 13th, was chiefly occupied by the evidence of the hospital physician and of Sir Bernard Spilsbury, who performed the autopsy. Sir Bernard then said that the body was that of a stout woman; the skin had a slight yellow tint, with no colour in the mucous membranes. There had been chronic osteo-arthritis of the spine and rheumatism. There was petechial hæmorrhage on the surface of the heart, which was enlarged; the cavities were all dilated, and there was a good deal of fatty disease of the muscle with brown atrophy, probably the result of the terminal pneumonia. The lungs were congested, especially the lower lobe, and there was acute broncho-pneumonia at the bases. The air-passages were reddened. The thyroid was somewhat small. The liver was rather fatty; there were small hæmorrhages in the spleen; the kidneys were enlarged and congested, and the suprarenals rather large. The tonsils showed acute inflammation, spreading over the wall of the pharynx, with some membrane on the surface. There was œdema of the glottis. A certain degree of chronic gastritis was found. The marrow in the shafts of the femora was a deep red. The evidence from the hospital where the woman died showed that the cause of death had been acute broncho-pneumonia. On admission the red cells had been normal but the white cells

numbered only 4400; this figure had subsequently dropped to 1000 and later risen to 2000, the terminal count. No polymorphonuclear cells had been found. The woman had been in hospital four days before she died. She had been regularly taking, for an unknown period, "HP Rheumatic Tablets" for her rheumatism.

At the second hearing the coroner said that he had adjourned the case primarily in order that the chemists who had sold the tablets might be able to give their point of view. One of the directors said that the tablets contained aspirin grs. $2\frac{1}{2}$, Pyramidon (amidopyrin) gr. $\frac{1}{2}$, and caffeine gr. $\frac{1}{2}$. They were identical with tablets sold by nearly every firm of manufacturing chemists. The prescription was on the bottle, and the tablets were packed by a well-known firm of wholesalers. His firm had sold them for several years but had never had a complaint before. Anticipating the coming into force of the Poisons Act on May 1st, 1936, the word "Poison" appeared on the label. Sir Bernard Spilsbury, in explaining the dangerous properties of pyramidon, said that the deceased had died from acute bronchopneumonia consequent upon agranulocytosis. During the last two or three years deaths had been reported as due to pyramidon, but they represented only a minute proportion of those who took the drug. The patients were not primarily susceptible but became so after taking it regularly for a long time; quite a small dose might then produce acute symptoms. The action was in this respect comparable with anaphylaxis. An eighth of a grain, he said, was a minute dose. In most fatal cases the patient had

taken the drug for a year or more; several weeks at least were required to produce sensitivity. An intractable sore-throat was a common symptom, for the blood condition lowered the resistance to infection. In the absence of bacteriological examination the condition might be taken for diphtheria, and had been so taken in a previous case before that court. In this case there was no evidence how many tablets the woman had taken; she must have had a good many bottles. The dose recommended on the bottle was two tablets three times a day. There was no question of an overdose. The body showed no general changes but only those produced by the agranulocytosis.

The coroner said that after the last case of the kind into which he had inquired he had communicated with the Poisons Board and the Home Office. He understood that provision was being made as from May 1st, 1936, to place pyramidon in the same group as the barbiturates, which would be controlled without being called "poisonous" or "dangerous." The need was to check the promiscuous sale of the drug. He proposed to refer this case also to the Poisons Board. The woman, he supposed, had been susceptible to pyramidon, and it was interesting to him that two such cases should have come before him within a short time. He accepted the evidence of the chemists that the drug had a perfectly proper use. It was important that general practitioners should know of the throat symptoms of agranulocytosis in order that they might distinguish it from diphtheria. He returned a verdict of death by misadventure.

PANEL AND CONTRACT PRACTICE

Conference Afterthoughts

PRACTITIONERS are sometimes in doubt as to whether they should be called upon to prescribe drugs and appliances for insured persons attending hospital. The relevant paragraph of the report of the Insurance Acts Committee, adopted after slight verbal amendment, indicates that—

When a patient is under the care of a hospital, institution or other doctor, it not infrequently happens that he returns with advice and suggestions to his family doctor as to the drugs and/or appliances to be ordered for him.

In the view of the I.A.C. a practitioner is called upon to prescribe for insured persons only during the time when he is actively engaged in treating them. His responsibility to prescribe ceases during the time the patient is in receipt of treatment by a member of a hospital medical staff.

As was the case last year, although the latest figures were satisfactory, London was criticised for the small percentage of its contribution to the National Insurance Defence Trust. Dr. Gregg objected to any suggestion that there was something mysterious about this. The London panel committee was doing its best to assist all forms of medical defence and he felt sure in due course would attain to 100 per cent. of its quota. Meanwhile it was paying also to another defence fund (that of the M.P.U.), the money subscribed, in the absence of precise instructions, being divided equally between the national fund and that of the union.

Warwickshire wanted the Ministry of Health to be asked to review the list of drugs and appliances included in the appendix to Part II. of the distribution scheme "so that certain obsolete articles could be excluded and certain modern and expensive prepara-

tions added." The wording of the resolution was perhaps hardly happy. Modern preparations are not always expensive. The list is of drugs and appliances which a practitioner may prescribe or supply (even if he is a prescribing practitioner) at the cost of the drug fund at the agreed tariff. It may, for instance, be more convenient for the doctor himself to supply a curative serum than to give the patient a prescription for it. It may be in the patient's interest that an elastic adhesive bandage should be applied forthwith in the surgery rather than that he should first have to fetch it from the chemist's. Dr. Dain reminded the conference that the list is continually being examined and revised.

Dental Letters

Dental benefit regulations under the National Health Insurance scheme were substantially modified at the beginning of the present half-year. Under these regulations documents known as dental letters are issued to members of approved societies in order to enable them to obtain dental treatment as insured persons. In his opening address to the recent winter session of the Dental Board of the United Kingdom, Sir Francis Acland drew public attention to the number of cases reported to the board on the ground that dental practitioners have obtained or might have obtained money under false pretences by giving incorrect certificates on these letters. In spite of the warning notice circulated in 1933 the practice still continues. Since the regulations of 1930 came into operation there have been 50 such charges. In about half of them the dentist's name is no longer on the register, either as a result of erasure (14) or by voluntary withdrawal. In 14 other cases the

discipline committee did not proceed to formulate a charge, and in 10 it was not thought necessary to erase the dentist's name. Sir Francis expressed the hope that the public attention directed to this reprehensible form of conduct would result in its diminution in the future. It should be noted that all those summoned to appear before the board on this charge appear in the register as "Dentist 1921" and the representative of dentists registered under the Dentists Act, 1921, has asked the board for a more honourable description than this in official documents. The chairman of the board agreed that if this description is regarded in any quarter as invidious the impression should be removed. There was a time when the term "panel doctor" was regarded almost as one of reproach, and it took some years for the public to realise that an insurance practitioner has to be a doctor first before he can join the medical list. The term "dentist 1921" does suggest sliding in through the side door, and its psychological effect can hardly be doubted. Legal advice has been taken and the question of an alternative title is to be considered at the next session of the Dental Board.

Extension of Benefits

At a conference of representatives of approved societies, insurance committees, and the British Medical Association held at B.M.A. House on Dec. 10th it was resolved:—

That this conference is strongly of the opinion that the addition of consultants and specialists and laboratory services to the benefits available under the National Health Insurance Acts is one of the utmost importance, and it was decided to appoint a committee, under the chairmanship of Dr. H. G. Dain, to bring forward suggestions for the provision of these services. Each of the three parties concerned in the conference is to appoint six members to serve on this committee.

Local Transfers: An Innovation

The Norfolk insurance committee, in agreement with the local panel committee, have adopted a new form of procedure in connexion with transfer of insured persons from one doctor's list to another. The regulations of 1931—which, by the way, are provisional regulations and have never been made substantive—provide that an insured person wishing to change his doctor, other than upon removal outside the area of the practice of his original doctor, shall be entitled to do so, if he has not later than the last day of February, May, August, or November in any year given notice to the committee in writing of his desire to transfer, whereupon he will be entitled to transfer as from the end of March, June, September, or December next following. He can of course change his doctor at any time with the written consent of both doctors. The Norfolk committee find that the majority of requests to transfer are based solely on the ground of convenience consequent upon removal. Although they have removed the insured persons in question are still within the district of the doctor upon whose list their names are included, but having moved nearer to another doctor practising in the district want to change on account of distance. The Norfolk committee propose giving effect to all requests for transfer where there has been a change of address and are asking practitioners in the area to agree to this course of action. The regulations will still apply where there has been no change of address. The insured person will then either have to obtain the consent of the

doctor for a transfer forthwith or give due notice to the insurance committee. The procedure in effect is asking the practitioners in the area to give a consent in advance to the immediate transfer of any insured person who has changed his address. It seems to be a common-sense arrangement for a rural area and will be watched with interest. We learn that the proposal has commended itself to nearly all the practitioners in the county.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Lt. Comdr. W. Flynn to rank of Surg. Comdr.
Surg. Lt. Comdr. J. G. Currie to *President* for course.
Surg. Lt. H. L. Cleave to *Maine*.
Surg. Lts. (D) A. MacD. Watson to *Barham*; and
F. R. McN. Willis to *Shropshire*.

ROYAL ARMY MEDICAL CORPS

Short Serv. Commissions.—Lts. J. Reeve, C. G. O'Driscoll, and L. E. Odum to be Capt's.

The results are announced of the examination (in written subjects) of officers with a view to promotion which was held at Home Stations last October. Among those successful are: Majors T. H. Twigg, A. J. Bado, F. K. Escritt, and L. Handy, and Capt. G. T. L. Archer, R.A.M.C.

REGULAR ARMY RESERVE OF OFFICERS

Lt. J. W. Walker, M.B., K. Afr. Rif., Res. of Off., to be Lt.

Maj. G. J. Keane, C.M.G., D.S.O., M.D., having attained the age limit of liability to recall ceases to belong to the Res. of Off.

MILITIA

Maj. J. Melvin, M.C., M.B., resigns his commn.
Maj. P. Walsh retires on attaining the age limit and retains the rank of Maj.

TERRITORIAL ARMY

Lts. A. M. Robertson and R. W. Nevin to be Capt's.

ROYAL AIR FORCE

Flying Offr. on probation James Patton Carlile relinquishes his short service commission on account of ill-health.

Flying Offrs. C. F. R. Briggs, H. D. Conway, L. M. Crooks, W. J. Fowler, I. K. Mackenzie, H. C. de B. Milne, D. J. Sheehan, and R. F. Wynroe, all to Medical Training Depôt, Halton, on appointment to short service commissions with effect from Dec. 2nd.

Dental Branch.—Flying Offrs. R. M. Brown and W. E. Nelson to Medical Training Depôt, Halton, on appointment to non-permanent commissions.

INDIAN MEDICAL SERVICE

Lt.-Col. W. J. Powell, C.I.E., to be Col.
Capt. R. A. Wesson to be Maj.
Capts. K. S. Fitch and S. C. H. Worseldine to be Maj's. (provl.).
Lt.-Col. C. A. Godson, M.C., retires.

THE BRITISH AMBULANCE SERVICE IN ETHIOPIA has been absorbed by the British Red Cross Society, and Sir Harold Fawcus, director-general of the society, has been appointed chairman of the committee with Mr. J. G. Rubio as secretary. All British Red Cross relief in Abyssinia will be dealt with by this committee, the offices of which have been removed from 33, Alfred-place, S.W.7, to the Red Cross headquarters, 14, Grosvenor-crescent, London, S.W.1.

CORRESPONDENCE

THE UNDESCENDED TESTICLE

To the Editor of THE LANCET

SIR,—The very interesting paper of Drs. Spence and Scowen in your issue of Dec. 14th confirms an opinion to which I came several years ago when discussing "undescended testicles" with those who were then treating them with thyroid extract. This opinion was that much argument within the profession, and many inaccurate forecasts delivered to the lay public, might be avoided if it were recognised that two quite distinct classes of pathological conditions were being lumped together.

The first class suffers from a delay in development, similar to the late eruption of teeth or the late development of pubic hair. To it belong about two-thirds of the cases sent me by physicians with a diagnosis of undescended testicles; and the proportion appears to me much the same in the series described. Perhaps, however, I should hesitate to put even in this class such cases as 18, 22, and 32, regarding them not so much as abnormal as falling short of an ideal. I always advise against operation in this class—though it is often performed, with on the whole the results one would expect when a demonstrably false anatomy is taught as its foundation. When adult nearly all of them are normal, though the cases described appear to prove conclusively that development can be hurried up by preparations such as Pregnyl.

The second class suffers from a congenital deformity, analogous to hare-lip or thyroglossal cyst; and like them is only amenable to surgery. To give hormone treatment in these cases a "trial before surgical measures are undertaken" is to inflict needless pain, expense, and disappointment. It is, of course, impossible within the limits of a letter to describe this class and its diagnosis, but its recognition seems to me to give that "hard-and-fast rule as to which type of case will be successful" whose absence is deplored. For instance, if Nos. 9, 14, 17, 20, 27, 28, 29, 30, 31 had all been regarded as needing operation because of the presence of hernial sacs, and No. 25 classed as the commonest variety of ectopia, the figures for hormone treatment would have been very much better.

I am, Sir, yours faithfully,

DENIS BROWNE.

Queen Anne-street, W., Dec. 17th.

CHRONIC NASAL SINUSITIS AND MENTAL DISORDER

To the Editor of THE LANCET

SIR,—Your footnote to Dr. Pickworth's letter of Nov. 9th (p. 1090) regarding controlled data is difficult to understand in relation to the ætiological viewpoint of mental disorder put forward in his book on this subject. For many years I have studied intimately the clinical association of focal infection and mental disorder, and have published a number of cases illustrating the beneficial effect on states of mental disorder of the eradication of such foci (THE LANCET, 1932, ii., 57 and 115), and I am not able to regard a difference between pyorrhœa and sinusitis as fundamental in the matter of causation as you suggest. Dr. Pickworth agrees on this point, and there is much clinical and histo-pathological evidence to support the view that *both* can act as sites for providing the cause of those particular physical brain changes to which mental disorder is probably due. Okell

and Elliott's findings (published in your issue of Oct. 19th, p. 869) of continued bacteriæmia in chronic pyorrhœa give sound pathological support to our past clinical observations.

The mentally healthy controls which you ask for are practicably unobtainable. If you had in mind an investigation of infirm patients, then I would point out that a large number of mental hospital patients are drawn from infirmaries, and in many other infirm patients a psychiatrist could readily detect mental changes, even if not present to a degree necessitating certification. To collect a series of control cases it would be necessary to make sure that they had pathological processes identical in nature, extent, and duration to those described in Dr. Pickworth's book, because the occurrence of chronic sinusitis in any given case merely indicates a *tendency* to mental disease and/or other systemic and allergic disorders.

I am, Sir, yours faithfully,

T. C. GRAVES.

Rubery Hill, Birmingham, Dec. 14th.

AN ALUMINIUM KETTLE

To the Editor of THE LANCET

SIR,—A patient of mine has been in the habit of drinking about 8 to 10 breakfast cups of tea during the day, using an aluminium kettle to boil the water. After about a month he began to suffer from stiffness and pain in the back of the neck and head. This got worse during the next two months, and eventually he consulted me. The stiffness and pain seemed to be of a rheumatic nature, and I rather suspected a doubtful-looking tooth to be the fons et origo. The usual remedies were tried without avail.

Some months later my patient, after reading a letter in the *Times* on aluminium poisoning from cooking vessels, resolved to stop using his kettle. The results were dramatic and beneficial, and he is now completely recovered. He naturally feels that the aluminium kettle has been the culprit. I do not know that aluminium can get into the system in this way, and if it can do so, that it will cause the above-mentioned symptoms, but shall be interested to know if any of your readers have had a similar experience.

I am, Sir, yours faithfully,

H. WILLMOTT ELWELL.

Mirfield, Yorkshire, Dec. 15th.

MEDICAL DEGREES OF CONTINENTAL UNIVERSITIES

To the Editor of THE LANCET

SIR,—A medical practitioner of my acquaintance, who thought of going abroad for post-graduate study, where he might at the same time prepare a thesis for the doctorate and thereby gain an M.D. degree, tells me he was discouraged from doing so by a high medical authority. But the fostering of post-graduate study in other States—for medicine, like music, is truly international—is most desirable, both from the scientific and the political points of view. Nearly all the earlier Presidents of the Royal College of Physicians of London were M.D.'s of Padua, Bologna, or other continental universities; later on they were admitted into the same degree at Oxford or Cambridge by incorporation, no tests or examinations being demanded. The standard of continental degrees is far higher to-day than it was then. Nor does the registrability of such degrees arise, since the registrability of degrees is a purely

political consideration. Registration of foreign degrees permitting the practice of physic over here depends upon whether British graduates or diplomates are admitted to the register permitting practice in the foreign country concerned. It is simply a question of international reciprocity. For example, for a time the M.D. degrees of the Belgian universities were registrable in this country; their holders were allowed on our register and permitted to practise here, and correspondingly our registered medical practitioners were allowed to practise in Belgium. Holders of the M.D. degree of the Royal Italian universities, or of the medical degrees (M.B. and M.D.) granted by imperial universities in Japan are entitled to have their names on the foreign list of our register and the privilege is reciprocal. But the cessation of this reciprocity would not affect the intrinsic value of the degrees. Of no lower standard or lesser worth are the medical degrees of German and Swiss State universities, not one of which admits to the British medical register. Nor does any British degree or diploma give its holder the right to practise in Germany or Switzerland, which have plenty of their own nationals and do not encourage foreigners to practise in their territories.

What then is the meaning of an M.D. degree from a continental university? It is precisely the same over here as an M.D. Oxon., Cantab., or Lond. is over there—i.e., purely an academic title much in the same sense as is a M.D. or D.Sc. Oxon., or a D.D. or LL.D. Cantab. All are simply university degrees. The medical authority quoted above was confusing a degree that admits to the register and entitles its holder to practise medicine in the country, with a degree which is purely a university title. A man may be registered in virtue of his M.R.C.S., L.R.C.P., but he may be as well M.A. Oxon., Ph.D. Lond., M.D. Geneva. The M.D. of Lausanne or Geneva is, as a university degree, every bit as good as an M.D. of Cambridge, Dublin, or Edinburgh; it costs far more, and takes far longer to secure. It would be only fair for all such continental M.D. degrees to be registrable by the General Medical Council as "additional titles by practitioners previously registered," as was the case with many of them before 1886.

I am, Sir, yours faithfully,

CHARLES A. H. FRANKLYN,
Hon. Secretary of the Lausanne Medical
Graduates' Association.

Lincoln, Dec. 15th.

REGULATION OF PROSTITUTION

To the Editor of THE LANCET

SIR,—I was surprised to read in Dr. D. White's letter that the examination of prostitutes in continental countries is a perfunctory procedure, taking one or two minutes. This may have been true at the time Flexner's book was published, but surely up-to-date and excellently managed clinics are now established in Paris and the leading French towns. These clinics are staffed by specialists provided with every modern facility for diagnosis, and the results show that brothels are not the source of contagion. Why, may I ask, has Germany returned to the system of regulation?

I am, Sir, yours faithfully,

Stamford, Dec. 17th.

C. ROLLESTON.

To the Editor of THE LANCET

SIR,—Dr. White makes no allowance for the difficulties of continental countries. Liable to invasion, they must keep preventable disease out

of their armies by the methods recommended by their own experts; the hardship of examination to a few women is nothing to that of conscription to all their men. We had such examination a few years ago—and may have still for all I know—in Malta and Gibraltar, our naval bases. In Egypt during the war we, as the protecting power, could under martial law have stopped the system there of examination, and the military authorities were asked to do so by a leading chaplain. But they refused to do so in the interests of our soldiers' health, and their strongest supporter in this was the English doctor at the head of the International Quarantine Board.

I am, Sir, yours faithfully,

Bournemouth, Dec. 16th.

TRAVELLER.

* * "Traveller" writes with the authority of a combatant officer who was on the spot. But, we believe, the argument that inspection of prostitutes protects troops has proved fallacious. Even in circumscribed areas like Malta and Gibraltar it produced a feeling of false security. Experience in Egypt during 1914-19 proved its worthlessness. There the regulations in force before the war were carried on, but the number of clandestine prostitutes was so great, and the examination of registered women so perfunctory, that it soon became evident that regulation and inspection, as carried out, were valueless.—E.V. L.

PAIN AND EUTHANASIA

To the Editor of THE LANCET

SIR.—Death is after all a rather radical way of abolishing pain, and I should like to associate myself with what Mr. Blundell Bankart has said in your issue of Dec. 21st, as I believe that there are very few cases of physical pain, no matter how severe, which, if drugs have failed to ease cannot be relieved by surgical means. Even before the failure of drugs to relieve, surgical relief is frequently advisable in order to prevent the demoralising effect of large doses of opiates. In common with others I have found bilateral division of the pain tracts in the cord a valuable procedure, giving relief to patients suffering from the severe pain of advanced malignant disease. The outlook for the patient may be brightened and entirely changed.

For those of us who believe that our duty is to fight for the life of our patient at all costs while at the same time doing all that we can for his comfort, surgery is a most efficient and useful weapon which as a means of relieving pain should not be overlooked.

I am, Sir, yours faithfully,

LAMBERT ROGERS.

Surgical Unit, the Royal Infirmary,
Cardiff, Dec. 22nd.

GLASGOW HOSPITAL EXTENSIONS.—The Glasgow corporation has approved the expenditure of £231,000 for the provision of further accommodation for nurses and patients in Glasgow mental institutions.

WINTFORD ORTHOPEDIC HOSPITAL.—Sir Francis Cowlin on Dec. 11th laid the foundation-stone of the new wards at this hospital school. It is hoped to increase the 68 beds now in use to over 100, and shareholders of Bristol Housing, Ltd., have provided £10,000 for this purpose. Facilities for education are available at the hospital, and the children have the benefit of country air.

OBITUARY

AUGUSTUS JOSEPH PEPPER, M.S. Lond.,
F.R.C.S. Eng.

THE death on Dec. 18th of Mr. A. J. Pepper at the age of 86 removes from the stage the almost legendary figure of a successful surgeon who became an official medico-legal expert. Mr. Pepper was educated at University College, London, of which later he was elected a fellow. After serving an apprenticeship with a medical practitioner in the midlands he entered U.C. Hospital with a scholarship. The name Augustus J. Pepper, of Harrowden, at the head of every list of prize-winners in each term soon became familiar in the school, and he showed his pre-eminence in the wider field of competition by winning

MR. PEPPER

three gold medals at the 1st M.D. Lond. examination and as many in the final with scholarships in medicine, surgery, and forensic medicine. He took the F.R.C.S. Eng. in 1876 and the M.S. of Lond. a year later. After being demonstrator of anatomy and surgical tutor at U.C.H. he accepted the invitation to become surgical tutor and pathologist at St. Mary's Hospital, where he soon showed that he could teach as well as learn. Teaching to him was a delight shared in by the students who attended in large numbers his demonstrations in the wards and the post-mortem rooms. In 1883 he published his handy "Elements of Surgical Pathology," which had a wide circulation and went through several editions. Appointed a supernumerary in 1880, he had a long spell as surgeon to out-patients at St. Mary's (1882-97) before reaching the full staff. In the meanwhile he was surgeon to the London Fever Hospital where, at a time when scarlet fever and diphtheria were of a severe type, he had many operations to perform, especially on mastoid cases.

When at last in 1897 (he was then 46) he became full surgeon to St. Mary's he fulfilled his early promise. He was an accomplished anatomist, full of resource, and a successful operator. Röntgen's discovery was not available at any rate during the early period of Pepper's career to unravel hidden mysteries, nor were all the recent advances in medical science at hand to aid in diagnosis, but Pepper's amazingly retentive recollection of all he had ever observed or heard afforded him a store-house of valuable experience. He gained a large private practice in Wimpole-street, which with his hospital work and the calls on him in forensic cases and contributions to the medical press made him a busy man. But mental work was to him an exhilarating exercise. He never tired and was always alert in body and mind. His devotion to medical jurisprudence was by no means an afterthought. As long ago as 1887 he gave a post-graduate course at St. Mary's on practical legal medicine, in which he described the situations that commonly come to the notice of the medical jurist and especially the various causes of sudden death. In one of these lectures he called attention

to the risk of injecting even dilute solutions of corrosive sublimate into body cavities owing to the risk of absorption and mercurial poisoning. While pathologist at St. Mary's he was frequently asked by the coroner for the district, the late Dr. Danford Thomas, to assist him by his evidence at inquests; this led to his being subsequently called on in the same capacity by the Crown in criminal cases, and he was in time appointed official pathologist to the Home Office. He appeared in the Euston-square and the Harley-street murder cases and other important trials. He was called in for the Crippen case, in which Willcox, Spilsbury, and A. P. Luff assisted him; he was a witness in the Druce case and helped to solve the Moat Farm mystery.

Pepper had many friends at University College, among them George Viner Ellis, for many years professor of anatomy there, who regarded Pepper as the most brilliant of the hundreds of students who had passed through his hands, and Pepper frequently stayed with him in Gloucestershire in later years and helped in the revision of Ellis's well-known "Demonstrations of Anatomy." Another intimate friend was his fellow student, Leander Starr Jameson of "Jameson raid" fame. Pepper was well read in English literature and was seldom at a loss for an apt quotation. He was of simple habits; he had nothing to conceal and was true and honest in all he said and did. He had little time for holidays, but enjoyed a day's shooting or a visit to a race-course.

Sir William Willcox writes: "Mr. Pepper was a short, well set, active man of very vivid personality. When confronted with any difficult surgical diagnosis he at once stripped the history of all extraneous matters and went straight to the point, making an exact diagnosis which was almost invariably correct. His clear mode of thinking and logical mind made him a brilliant, popular, and impressive clinical teacher and lecturer. In the operating theatre he was at his best. His precise knowledge of anatomy and pathology made him perfectly at home even in the most difficult operations, and his courage and resource in sudden emergencies were outstanding. When his surgical dresser in 1898 I well remember his removing a large cirroid aneurysm of the ear in a young woman. The case had often been shown at the F.R.C.S. examinations and any candidate who advised operation was severely criticised for recommending the impossible. This case came under Pepper's care when operation was the only chance of saving the patient's life owing to recurring hæmorrhages. Pepper operated in the presence of a crowded theatre of students, and as one of his assistants I well remember the furious hæmorrhages which occurred, necessitating the use of all the Spencer Wells forceps in the theatre. Pepper went on with the operation, cool and undaunted, and successfully completed it. The young woman made a good recovery and afterwards married and had a large family.

"Pepper was much loved and admired by the students who crowded to his lectures and clinical rounds. He was a loyal and greatly appreciated colleague who was always ready to give freely of his knowledge and experience to his fellow members of the staff. He figured in many famous criminal cases; the last case in which he participated was the Crippen case in which he was assisted by Spilsbury and myself. His logical mind and incisive expression

made him an expert witness whose testimony held good in spite of cross-examination however severe. Indeed he was treated with great respect and caution by cross-examining counsel.

"In private life Pepper was of a somewhat retiring disposition. His intimate friends knew that he was a fine whist player, fond of country life and of his garden in which he was an expert horticulturist. His colleagues and friends will always remember the inspiration they received from his lovable and impressive personality."

Sir Bernard Spilsbury adds: "My acquaintance with Mr. Pepper dates from 1902, when I became his surgical dresser at St. Mary's Hospital. What impressed us as students was his quiet, confident bearing. He never became flustered or lost his temper, and was prompt and sure of himself in an emergency; we came to realise later his complete competence as a surgeon. Even though he occasionally stroked his moustache during an operation—these were the days before masks were worn—we seldom saw post-operative sepsis in his wards; indeed, complications of any kind were rare. I well remember on one occasion his seeing for the first time a patient with sarcoma of the antrum which had been pronounced inoperable. After a brief examination he gave a demonstration on the case to his class, and within an hour, in the course of the afternoon's operations, he did a total excision of the upper jaw. The patient made an uninterrupted recovery and returned to the hospital three months later to have an artificial jaw made. I have known him, when asked by a medical colleague to examine one of his patients as a possible acute abdomen, to borrow a stethoscope and demonstrate pneumonia of the base of the lung as the explanation of his symptoms. Later, when I became pathologist to St. Mary's, Pepper impressed me by his thorough knowledge of pathology and histology; he was quick to recognise the detailed structure of a difficult microscopical preparation and very sound in his interpretation. When we became associated in medico-legal work he exhibited the same qualities, an absolute certainty of his facts and a quiet competence in the witness-box, which, whilst it made a great impression upon the jury, was the despair of opposing counsel. He was a quiet, reserved man, alert and shrewd, with a fund of common sense, ever ready with a word of encouragement. The pupil who did his best was never forgotten, and had in Pepper a friend for life."

Mr. Pepper is survived by his widow. There were no children of the marriage.

**SIR HILARION MARCUS FERNANDO, J.P.,
M.D., B.Sc. Lond.**

Sir Marcus Fernando, who died in London on Dec. 18th at the age of 71, was a leader of the profession in Ceylon. A member of a family with old associations on the island, where he himself owned considerable property, he also took an active part in legislation and was knighted in 1923 for his public services. At the age of 19 he was elected Ceylon Government scholar and Gilchrist scholar for the East from the Royal College, Colombo, and he studied medicine at University College, London, where he obtained the Atchison and entrance scholarships. He was elected Fellow of the College in 1890. He qualified in 1888, having won the gold medal in physiology, medicine, and forensic medicine. He gained the M.D. in the following year and returned

to Ceylon. There he was registrar of the Medical College and first physician of the General Hospital, being recognised both by his colleagues and by the Government as an authority on malaria and plague. When he retired from the medical service in 1909, he devoted his attention to public work and became a member of the legislative and executive councils, a magistrate and the president of the Catholic Union. He married Margaret Francis Mary, daughter of Lady de Soysa, of Colombo, and had a son and a daughter.

FREDERICK SHAW, M.C., M.B. Dub.

WE regret to record the death of Dr. "Freddie" Shaw, chief medical officer to the Iraq Petroleum Company. The elder son of the late Horace C. F. Shaw, a prominent official of the Irish Land Commission, and a cousin of Mr. G. B. Shaw, Frederick Roland Studdert Shaw was born in Dublin in 1892, and graduated in medicine at Trinity College in 1915, passing forthwith into the Royal Army Medical Corps, and proceeding to France where he served throughout the remainder of the war and gained the Military Cross. Transferred after the war to India he commanded a motor ambulance convoy on the frontier, and did sterling work during a serious cholera epidemic in Waziristan. His next appointment was on the staff of Sir Charles Burchaell, then director of medical services, from which he was transferred for service with the Iraq levies. During the Kurdish revolt in 1922 Captain Shaw was instrumental in obtaining the release of two R.A.F. officers who had been captured by Sheik Ahmed against whom a column was operating. Being given permission to enter the country he proceeded alone and unarmed to visit these prisoners, and ultimately effected their release. On resigning his commission he joined the Iraq Petroleum Company in October, 1927, and did pioneer work whilst the company was in its infancy. During the pipe line construction he initiated and supervised the medical and sanitary arrangements, later becoming chief medical officer. He was returning from a visit by plane to see a sick colleague at Kirkuk and had landed at Haditha where the apparently mild attack of tonsillitis from which he was suffering took a rapidly fatal turn. Captain Shaw was a fine athlete and cricketer. While a student at Dublin he was 100 and 220 yards champion of Ireland, and won the vice-chancellor's cup. He also captained the Dublin University and Gentlemen of Ireland cricket team, and later played for the Army on several occasions. Unassuming in manner he was a keen and capable medical officer, sanitarian, and administrator, an excellent chief and colleague, and a good companion whose loss will be felt by a large circle of friends in the Near East and India. He is survived by his widow and two children.

**FRANK CHETWODE CRAWLEY, M.D. Dub.,
F.R.C.S. Irel.**

AFTER only a few days' illness Mr. Frank Crawley died on Dec. 16th, at the age of 64. His term of office as president of the Royal College of Surgeons in Ireland ended last year.

By birth a Dublin man, he was educated at Shrewsbury, at Cambridge, and at Trinity College, Dublin, where he graduated in medicine in 1896. He was admitted to the fellowship of the Royal College of Surgeons in Ireland in 1900, and his choice from the first was the field of ophthalmic surgery,

with which for some years he combined the surgery of the throat, nose, and ear. Soon after qualification he was appointed house surgeon to St. Mark's Ophthalmic Hospital, Dublin (now merged in the Royal Victoria Eye and Ear Hospital), where he spent some years, and he subsequently worked in Vienna and Berlin. After that he practised his specialty in Dublin. In 1917 he spent some months in the British Expeditionary Force in France as a member of the staff of the "83 (Dublin) General Hospital." For many years a member of the council of the Royal College of Surgeons in Ireland, in 1932 he was induced to accept the presidency, and held this office until June, 1934. At the time of his death he was senior surgeon to the Royal Victoria Eye and Ear Hospital, ophthalmic surgeon to the Royal City of Dublin Hospital, and consulting ophthalmic surgeon to the Rotunda Hospital and to the Molyneux Asylum for the Blind.

In his younger professional days Crawley made many communications to the *Proceedings* of the Royal Academy of Medicine and other medical

publications. In later years the demands of a large private practice, in addition to his hospital work, stood in the way of much writing, but never interfered with his scientific interests or his keeping in touch with modern development. "In his own specialty," writes our Dublin correspondent, "he was at once a cool and successful operator on the eye and a consultant whose view was not limited to the eye. In particular, in medical cases in which there were ophthalmic complications, physicians found him an ally of resource and strength. He disliked publicity and took little part in public medical affairs, but when the responsibility of office came on him as president of his College he showed great capacity for affairs. He gave a personal attention to matters of detail and brought an independent judgment to every problem which came before him. In social life he was the most pleasant of companions, cultured, gay, and kindly. Everyone who met him recognised his intelligence, his directness, his uprightness; when one knew him better one recognised also the good heart which made him the most steadfast of friends."

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Christmas Adjournment

BOTH Houses of Parliament adjourned on Friday, Dec. 20th, for the Christmas recess. They will reassemble on Feb. 4th.

HOUSE OF COMMONS

MONDAY, DEC. 16TH

Hospital Treatment of Ex-Service Men

Mr. GIBBINS asked the Minister of Pensions the number of ex-Service men receiving treatment by the Ministry of Pensions hospitals without receiving treatment allowances.—Mr. R. S. HUNSON replied: I regret that statistics such as the hon. Member requests are not regularly collected. I am, however, satisfied from the reports I have received that every case in which a loss of wages or profits has been sustained by a man who was employed before admission to hospital, or in which a corresponding loss of benefit or grant in respect of unemployment was necessitated by such admission, should now, with the aid of the supplementary grant scheme which I announced in the House on Oct. 22nd last, be substantially met by the grant of allowances of whatever kind may be appropriate to the case.

Government's Pure Milk Policy

Sir PERCY HURD asked the Prime Minister whether he was aware of the hindrance to progress in the milk policy of the Government arising from methods of administration under which the Ministry of Health supervised the production of Certified and Grade A (T.T.) milk, while the Ministry of Agriculture promoted a scheme dealing with tuberculosis in dairy herds and the Milk Marketing Board had an accredited herd scheme on different lines; and whether steps could be taken to co-ordinate these services and so abate confusion and discouragement in the production of milk of approved quality.—Mr. BALDWIN replied: I am not aware that any hindrance is caused to the milk policy of the Government by reason of the facts referred to. There is full consultation between the Ministry of Health and the Ministry of Agriculture in matters affecting the quality of the milk-supply, and it is their practice to ascertain the views of the Milk Marketing Board on all questions in which the Board are concerned.

Hospitals and Telephone Charges

Mr. DONNER asked the Postmaster-General whether he was aware that the Andover War Memorial Hospital

have, in view of their services to the community, appealed to the telephone department to be charged at the private residence rate and not at the business rate, and that the application had been refused; and whether he would take steps to lighten this burden on institutions of this nature.—Major TRYON replied: Unfortunately, it is not possible to view this application in isolation. There are many institutions—apart from hospitals—which are of undoubted service to the community and in relation to which a similar claim might be made. It would be impossible to discriminate between them, and, if the desired concession were made to all, the loss of revenue would be considerable while the relief to the individual institutions concerned would be comparatively small. In view of this and of the difficulty of maintaining the distinction between the business and the private residence rates if concessions are made which are at variance with the principles on which that distinction is founded, I have felt compelled to refuse to make exceptions to the general regulations in the case of any institution, deserving though it may be of sympathy and support.

Footwear for Necessitous Children

Miss WILKINSON asked the Minister of Health whether he was prepared to introduce legislation to enable local authorities to levy a rate for the provision of footwear for necessitous children.—Mr. SHAKESPEARE replied: No, Sir. There is no necessity for such legislation. Public assistance authorities already have power to provide adequate relief in all cases of need, and relief may be in money or in kind as may be appropriate to the particular circumstances.

Composition and Description of Foods

Sir ARNOLD WILSON asked the Minister of Health whether and, if so, when he proposed to introduce legislation to give effect to the recommendations of the report of the departmental committee on the composition and description of food and, in particular, for the revision and consolidation of statute law on the subject.—Sir KINGSLEY WOOD replied: Legislation to consolidate the law relating to local government and public health is being prepared by a committee which will in due course take up the question of consolidating food legislation.

TUESDAY, DEC. 17TH

Safety of Workers in Mines: Royal Commission

Miss WARD asked the Prime Minister whether he was now in a position to make an announcement about the proposed Royal Commission to inquire into the provisions for the safety of workers in mines.—Mr. BALDWIN replied: I am able to announce that His Majesty has been pleased

to improve the appointment of the following to serve on the Commission: Lord Rockley (chairman), His Honour the Judge George Clarence Allsebrook, Sir Malcolm Delevingne, Sir Henry Walker, Mr. D. R. Grenfell, M.P., Mr. Edward Otto Forster Brown, Mr. Ebby Edwards, Mr. William Thomas Miller, Mr. William Hamilton Telfer, and Mr. John Walker. The terms of reference are: To inquire whether the safety and health of mine workers can be better ensured by extending or modifying the principles or general provisions of the Coal Mines Act, 1911, or the arrangements for its administration, having regard to the changes that have taken place in organisation, methods of work, and equipment since it became law, and the experience gained; and to make recommendations.

WEDNESDAY, DEC. 18TH

Enteric Fever in Palestine

Lord ARSLEY asked the Secretary of State for the Colonies whether, in respect of the recent epidemic of enteric fever among the British police stationed at Jerusalem, any arrangements had been made for the convalescence of members of this force; and, if not, whether he would be willing to consider the provision of such.—Mr. THOMAS replied: There has been no epidemic of enteric in the British section of the Palestine police at Jerusalem or elsewhere. Only six cases have occurred this year, of which four have been discharged from hospital completely cured. The two others are progressing satisfactorily.

THURSDAY, DEC. 19TH

Poisons List and Rules

Mr. HALL-CAINE asked the Home Secretary when regulations were likely to be introduced to bring into effect the recent recommendations of the Poisons Board; and whether such regulations would vary in any way these recommendations.—Sir JOHN SIMON replied: The Poison List and Rules will be issued at the end of the present month. There are certain differences from the original recommendations, but the modifications have been decided upon after consultation with the Board.

Hospital Patients and Polling Facilities

Major GUEST asked the Home Secretary whether he would consider the possibility of providing facilities to enable hospital patients to record their votes at elections if on the register.—Sir JOHN SIMON replied: I will have my hon. friend's suggestion noted for consideration in connexion with any opportunity that might arise for reviewing the present system of voting by post.

Governor of Holloway Prison

Mr. PETHICK-LAWRENCE asked the Home Secretary whether, when he was appointing a governor of Holloway prison in the place of the late Dr. Morton, he would consider the advisability of appointing a woman to that position.—Sir JOHN SIMON replied: The vacancy in the governorship of Holloway prison was filled in July, after carefully considering all the circumstances, by the appointment of Dr. J. C. McI. Matheson, D.S.O.

Black-listed Schools

Mr. KIRBY asked the President of the Board of Education the number of elementary schools in Liverpool which had been black-listed; and what steps were being taken to place such schools in a satisfactory state either by reconstruction or replacement.—Mr. OLIVER STANLEY replied: The number of public elementary schools in Liverpool which are still on the list of schools with defective premises is 34. The problem which these schools present cannot be satisfactorily solved by their treatment in isolation from one another or without due regard to housing difficulties. The Board are in consultation with the local education authority and the authorities of the non-provided schools with a view to assisting them to formulate a comprehensive plan for dealing with the problem.

Mr. THURTELL asked the President of the Board of Education how many schools were now black-listed; and how many of these were non-provided schools.—Mr. OLIVER STANLEY replied: The number of schools on the list of

schools with defective premises is now 1104, of which 772 are non-provided schools.

Physical Training at Schools

Mr. RANKIN asked the President of the Board of Education what was the present approximate annual contribution made by way of Government grant to assist the provision of gymnasiums, playing fields, and physical training organisers at elementary and secondary schools in Great Britain; and whether he was satisfied that progress in the provision of such necessary amenities was proceeding satisfactorily.—Mr. OLIVER STANLEY replied: It is estimated that during the current financial year a grant of approximately £35,000 will be paid for the organisation of physical training in public elementary schools. The corresponding figure for secondary schools cannot be ascertained. As the expenditure on gymnasia and playing fields is not returned as a separate item in the local education authorities' accounts, I regret that I am unable to answer the hon. Member's question on this point. As regards the second part of the question, the Government are anxious to accelerate progress with the provision of facilities for physical training, and I am proposing to issue a circular to local education authorities on the matter in the near future.

Malnutrition in Lancashire

Mr. SILVERMAN asked the President of the Board of Education whether he had considered the statement of the responsible medical officers that malnutrition among Lancashire school-children had seriously increased; and what steps, if any, he was prepared to take to remedy this state of affairs.—Mr. OLIVER STANLEY replied: In his annual report for the year 1934 the school medical officer for Lancashire gives particulars of an increase in malnutrition from 1.75 per cent. in 1933 to 2.19 per cent. in 1934 amongst routine cases. In 1930 the percentage was 2.16. As regards the second part of the question the school medical officer explains in his report that the provision of free meals and milk is more than keeping pace with the malnutrition discovered at medical inspections.

Free Milk for Necessitous School-children

Brig.-General SPEARS asked the President of the Board of Education whether he would issue instructions that free milk should be given to all children of school age whose parents were unemployed persons on the means test, in view of the desirability of the maximum number of children getting milk at school and of the fact that unemployed persons on the means test could not in most cases afford to pay for milk for their children.—Mr. OLIVER STANLEY replied: The conditions under which local education authorities may provide free milk for children attending public elementary schools are governed by the terms of Section 84 of the Education Act, 1921, and under that section I have no power to issue the instructions which my hon. friend desires. I would invite the attention of the hon. Member to the Board's Circular 1443 which sets out the Board's policy on the selection of children for provision of meals.

National Maternity Service

Mr. DAY asked the Minister of Health whether he had considered the copy of the resolution unanimously recommended by the council of the British Medical Association, urging the appointment of a national maternity service; and whether he would consider introducing legislation to give effect to the suggestions contained in the resolution.—Sir KINGSLEY WOOD replied: I have received a copy of the memorandum referred to by the hon. Member and I will give it my careful consideration. I cannot at present undertake to introduce legislation on this subject beyond that already promised for securing an organised service of salaried midwives.

Overcrowded Houses

Sir FRANCIS FRENANTLE asked the Minister of Health if he was aware that, until he had declared the appointed day under Section 3 of the Housing Act, 1935, new tenants might be added without offence and, in fact, were being so added to already overcrowded houses; and if he would state how soon he would be able to declare the appointed day, respectively, for London and the area.—Sir

KINGSLEY WOOD replied: I am aware of the desirability of fixing the appointed day in such a way as to minimise the difficulties to which my hon. friend refers, but I must take into account progress made in the provision of new accommodation required for the abatement of overcrowding.

Sterilisation

Sir ARNOLD WILSON asked the Minister of Health whether and, if so, when he proposed to introduce legislation to give effect to the recommendations of the report of the departmental committee on sterilisation (Cmd. 4485, 1933); and what had been the results of his consultation through the Board of Control with the Medical Research Council and the Registrar-General.—Sir KINGSLEY WOOD replied: The Government do not propose to introduce legislation for this purpose at present. The consultation referred to in the latter part of the question is not complete, and inquiries on certain matters on which research was recommended by the departmental committee are still in progress.

Anæsthetics in Animal Experiment

Mr. GROVES asked the Home Secretary whether electric immobilisation or injection of starch grains into the carotid artery were held as complying with the provisions as to anæsthetics under the Act 39 and 40 Vic., c. 77, relating to experiments on animals; whether he was aware that these respective methods were in use for the purpose of producing anæsthesia in experiments on animals; and whether there were any specific regulations laid down in connexion with the granting of licences for such experimentation as to what did, or did not, constitute an anæsthetic within the meaning of the Act.—Mr. GEOFFREY LLOYD replied: I am advised that electric immobilisation and the injection of starch grains into the carotid artery are effective methods of causing complete insensibility in animals, but they are never used in the laboratories as substitutes for the recognised anæsthetics. There are no specific regulations defining anæsthetics and there is no definition in the Act, but there is attached to every Certificate B (the certificate permitting cutting operations with subsequent recovery) a condition requiring that the anæsthetic administered must be of sufficient power to prevent the animal feeling pain.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 14TH, 1935.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2636; diphtheria, 1234; enteric fever, 29; acute pneumonia (primary or influenzal), 952; puerperal fever, 42; puerperal pyrexia, 96; cerebro-spinal fever, 17; acute poliomyelitis, 4; acute polio-encephalitis, 1; encephalitis lethargica, 3; dysentery, 33; ophthalmia neonatorum, 55. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Dec. 20th was 3467, which included: Scarlet fever, 1120; diphtheria, 1273; measles, 203; whooping-cough, 355; puerperal fever, 21 mothers (plus 13 babies); encephalitis lethargica, 279; poliomyelitis, 4. At St. Margaret's Hospital there were 17 babies (plus 4 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (1) from enteric fever, 30 (3) from measles, 6 (1) from scarlet fever, 15 (3) from whooping-cough, 36 (5) from diphtheria, 39 (11) from diarrhoea and enteritis under two years, and 62 (11) from influenza. The figures in parentheses are those for London itself.

Liverpool reported 11 deaths from measles, Middlesbrough 3, Walthamstow, Manchester, and had 3 fatal cases of whooping-cough reported.

Manchester, 3 from Birmingham, 2 each from Portsmouth, Leeds, and Newcastle-on-Tyne. The mortality from influenza is scattered over 29 great towns, Liverpool reporting 6, Manchester and Birmingham each 5, Burnley 3.

The number of stillbirths notified during the week was 256 (corresponding to a rate of 44 per 1000 total births), including 42 in London.

KING EDWARD'S HOSPITAL FUND

A JUBILEE DISTRIBUTION

ADDRESSING the general council of King Edward's Hospital Fund for London on Dec. 17th the Prince of Wales as president announced that the ordinary annual distribution of £300,000 is to be supplemented this year by a Silver Jubilee distribution of £120,000. Most of this sum (£109,000) is taken from accumulated surpluses; the remainder comes from the sale of seats at the two Jubilee processions, allotted to the Fund by the Office of Works. The additional distribution is designed to meet one of the most urgent needs of the present moment. Since the financial crisis of 1931 the hospitals, with few exceptions, have succeeded in raising enough money to maintain their beds, but have not been able to do as much as usual to bring their buildings and equipment up to date, many urgent schemes of extension and improvement being deferred. It is to the assistance of such schemes, and of others which have been completed but not fully paid for, that the Silver Jubilee distribution is being devoted. The grants, of course, can cover only a small proportion of the cost of each scheme. "For the rest," said the Prince, "the hospitals must rely on the generosity and sympathy of the public, already shown by the fact that during the last five difficult years £550,000 a year has been received by hospitals in London for these purposes, in addition to £1,300,000 a year in voluntary gifts to maintenance."

The total distribution by the Fund on Dec. 18th, including £5000 for pensions, thus amounts to £425,000. Since 1931, when an ordinary distribution of £300,000 a year was initiated to meet the emergency, it has been difficult to provide this sum out of annual receipts, and this year the grants are not yet wholly covered. The deficiency (about £7000 last week) would be greater but for an anonymous donation of £15,000, the ninth from the same donor during the past 13 years. The fall in interest rates is reducing investment income, and the Prince appealed for the help of new contributors to make good the loss. He pointed out that during the past 25 years the average annual increase in distribution had been about £7000, whereas during the nine years when King George was president of the Fund the ordinary distribution had increased from £50,000 to £150,000—an average increase of £11,000. This was a challenge to the present generation, and he thought it should be possible, in the improving circumstances of the times, to raise the sum required each year without competing with contributions to individual hospitals. A central Fund provided facilities for benefactors who were not specially interested in any particular hospital and were not in a position to judge between their respective claims. It was noteworthy that the Bank of England, having recently increased their contribution to hospitals, had asked the Fund to allocate it on their behalf—a request which was much appreciated. The Fund would gladly do the same service for other donors. Another new piece of work undertaken was a grant towards the services of District Nursing Associations. So far only £2000 could be spared for the purpose, but the Fund would like to offer more support, partly because it wished to help the excellent work of district nurses and partly because this work lessened congestion in hospital out-patient departments. One of the claims of the Fund to public support is that it exercises many of the functions of a central

for the hospitals of London. In this connexion Prince referred to its memoranda on time-saving aids in out-patient departments, its inquiry into the hours of waking patients, and its procedure in the detailed examination of building schemes. "As noteworthy," he said, "that nearly 1000 new beds had been provided since 1931 and that more than 2000 were proposed, apart from pay beds and future extensions."

These figures," he added, "suggest two things. One is the remarkable vitality of the voluntary hospital system, which goes on growing at this rate, at a time when so many people suffer from an apparently incurable condition that it is dead. The other is that, if the voluntary hospital service is to continue to live and grow on the scale in present-day conditions, the individual hospitals must realise that they are parts of one service, and each must have regard to the collective interests of the whole. The King's Fund, as a central body, calls attention to the total liability involved in all these decisions."

It was satisfactory to see that the hospitals were adding to the number of pay beds, of which there was still a real shortage.

After speaking of the recent amalgamation between the London Voluntary Hospitals Committee and the London regional committee of the British Hospitals Association, the Prince concluded by mentioning another great co-operative effort on the part of the hospitals, helped and indeed largely stimulated by the "King's Fund"—namely, the Federated Superannuation Scheme for Nurses and Hospital Officers. In the first seven years during which the Fund promised financial grants had now expired and the scheme was firmly established, having been adopted by 88 per cent. of the hospitals of London or 73 per cent. of those in Great Britain as a whole, reckoned on a bed basis. The £5000 allocated to pensions covers the first three months of the initial period. The expenditure of the hospitals on the scheme will now be regarded as part of their normal outgoings, which will be taken into account by the Fund in making the financial grants.

Under the Silver Jubilee distribution 76 hospitals have received grants towards capital expenditure. Those which benefit by sums of £1000 or more are the following:—

Beckenham Hospital (£1000); Bolingbroke Hospital (£1000); British Hospital for Mothers and Babies, Woolwich (£1250); Central London Throat, Nose, and Ear Hospital (£1000); Charing Cross Hospital (£2000); Ednought Hospital, Greenwich (£2500); Elizabeth Garrett Anderson Hospital (£1000); German Hospital (£1000); Guy's Hospital (£2000); Hospital for Consumption, Brompton (£1000); Hospital for Sick Children, at Ormond-street (£10,000); King George Hospital, at Ormond-street (£10,000); King's College Hospital (£2500); London Hospital (£3000); London Jewish Hospital (£1500); Metropolitan Hospital (£2500); Middlesex Hospital (£1000); Miller General Hospital for South-east London (£500); National Hospital, Queen-square (£5000); Royal Free Hospital (£2000); Prince of Wales's Hospital (£2500); Princess Elizabeth of York Hospital for Children (£5000); Queen Charlotte's Maternity Hospital (£4500); Queen's Hospital for Children (£1000); Royal Eye Hospital (£2500); Royal Northern Hospital (£1250); St. Bartholomew's Hospital (£2500); St. George's Hospital (£3000); St. Mark's Hospital (£1000); St. Mary's Hospital (£4000); St. Thomas's Hospital (£1000); South London Hospital for Women (£500); University College Hospital (£5000); Westminster Hospital (£2000); Westminster Hospital (£10,000); Redden General Hospital (£3000); Woolwich and District War Memorial Hospital (£3500).

In view of these contributions to capital schemes, the smaller proportion than usual of the £300,000

distributed in ordinary grants will go to such objects and a larger proportion to maintenance. The maintenance grants will amount to £272,850 as compared with £254,375 last year, and will be "mainly allocated to the reduction of debt resulting from past deficits at hospitals which have had exceptional difficulty in coping with financial depression."

BUCHAREST

(FROM OUR OWN CORRESPONDENT)

SICKNESS INSURANCE IN JUGOSLAVIA

THE first social insurance Act in Jugoslavia was passed in 1901 and amended in 1908 and in 1925. As the law now stands there is compulsory insurance for all industrial workers and for all workers in trade and agriculture whose annual income is under 10,000 dinars (about £50). Each district has its own independent pay office, and there are also a very few so-called company pay offices. Each pay office has an executive board of 9 or 12 members, half elected from the employees and half from the employers, and each office is responsible to the Supreme Insurance Sickness Council on which the medical profession has many representatives. Two-thirds of the contributions to the scheme are made by the employees and one-third by the employers, while the State bears half the cost of the administration of the district pay offices. Members may receive free medical attendance, medicine, appliances, and hospital treatment, together with a sickness benefit amounting to half their wages for a maximum period of 26 weeks. Dependants receive benefits only when the financial position of the pay offices permits, and in all cases the pay offices have the right to insist that one-quarter of the benefits received shall have been contributed by the member himself. The pay offices employ their own medical officers, but members have the right to consult any other doctor they may choose, and the pay offices then pay the private doctor at their usual panel rate. There are altogether 154 panel doctors in Jugoslavia, and they are paid according to their attendances at a minimum scale fixed by the National Medical Association for private physicians. In 1934 the average fee for a consultation was 10 dinars (about one shilling), for a visit 15 dinars, and for a night visit 30 dinars. Medical payments are under the control of a committee which is appointed by the syndicate of doctors, and consists of three doctors, one dentist, and ex officio the principal doctor of the pay office concerned. The choice of drugs is left to the discretion of the panel doctors, but a hint is given to them as to the possibility of choosing the less expensive remedies and to refrain from needlessly ordering expensive foreign proprietary preparations. The prescriptions are supervised by the doctors and pharmacists of the insurance offices. Chemists must give a reduction of 20 per cent. on their ordinary prices, and if their yearly bill exceeds 15,000 dinars (about £75) the rebate is 25 per cent. The sickness allowances are arranged by the panel doctors. The number of members, inclusive of dependants, amounts to 14.3 per cent. of the population.

REGULATION OF RUMANIAN MANUFACTURING CHEMISTS

Owing to the currency restriction Act importers of foreign drugs have to pay 44 per cent. more for the goods they buy abroad to make up the difference between the quotation price and the selling price

of foreign currencies. As a result the price of all imported drugs has been raised by 50 per cent. The home manufacturing chemists have taken advantage of this to raise their prices by 44 per cent., arguing that the prices of the raw materials used in the manufacture of their products had been increased by this amount. The Government has protested against this attitude on the grounds that only one-fifth of the raw materials are imported from abroad, and they regard the increase in price as an unjust and unjustifiable exploitation of the public. An order has therefore been issued for the reduction of the prices to their former level on pain of heavy penalties. It is not only since the import price has been raised that foreign drugs have become dear. Last year a kilo of aspirin cost 3000 lei wholesale; now it costs 4000 lei, while its retail price has risen from 3600 to 4800 lei. Last year one kilo of pyramidon cost 13,000 lei, now it costs 18,000 lei; similarly the wholesale price of quinine has risen from 3400 to 4500 and the retail price from 5000 to 7000 lei. English drugs show the greatest increase in price (50 per cent.), then French (40 per cent.), and then Italian (25-30 per cent.). Italian products

are fairly widely used here. The extraordinary rise in price is detrimental not only to the chemists but also the medical profession, for many patients refrain from consulting a doctor simply because they are afraid they will not be able to afford to pay for the drugs ordered.

A NEW JOURNAL ON RABIES

Under the title *Buletinul Serviciului Antirabic* a new periodical has been launched under the auspices of the staff of the Bucharest Babes Institute. This institute was named after its founder Prof. Babes, who started his career at Budapest as assistant to Prof. Högyes; its present director, Prof. Proca, is the editor of the new journal. For the present the journal will appear as a quarterly, but if sufficient interest is aroused it will later be issued as a monthly. In its first number it is stated that during last year the five antirabic institutes of Rumania inoculated 21,000 persons, while in Germany only 138 persons were inoculated. During the first eight months of this year the Babes Institute alone has treated 7434 patients bitten by dogs. In Rumania there were 126 deaths in 1934.

MEDICAL NEWS

University of Cambridge

On Dec. 19th the following degrees were conferred:—

M.B., B.Chir.—D. G. Allen.

B.Chir.—Robert Anderson and C. W. Thomas.

Royal College of Surgeons of England

At the primary examination for the fellowship held during December 228 candidates presented themselves, of whom 70 were approved and 158 rejected. The following are the names and medical schools of the successful candidates:—

H. H. Barst, Middlesex; G. M. Bastedo, M.D. Toronto, Middlesex; R. L. Benison, M.B. Camb., St. Bart.'s; B. B. Bhatia, M.B. Lucknow, Univ. Coll. and Middlesex; J. W. Bone, M.B. Glasg., Univ. Coll.; J. B. Cadas, M.B. Glasg., St. Mary's; R. I. Campbell, M.B. Sydney; A. H. Charles, M.B. Camb., Middlesex; W. S. Charlton, M.B. Sydney, Middlesex; G. R. Clarke, M.B. Birm., King's Coll.; E. P. Connolly, M.B. Sydney, King's Coll.; H. G. N. Cooper, B.M. Oxon, Guy's; J. W. Cope, B.Chir. Camb., St. Bart.'s; R. V. Coxon, Guy's; C. F. Critchley, M.B. Lond., St. Thos. and Middlesex; A. J. Daly, Middlesex and Univ. Coll.; D. R. Davies, M.B. Lond., Univ. Coll.; A. P. Dick, Camb. and Lond.; C. D. Donald, M.B. Melb., Middlesex; M. Fatin, M.B. Cairo, Guy's; H. C. Fletcher-Jones, M.B. Lond., Univ. Coll. and Middlesex; S. Green, Guy's; M. T. Greig, M.B. N.Z., Otago and Middlesex; R. W. Gunderson, Middlesex; T. D. Hagger, M.D. Melb., Univ. Coll.; R. Sampson Handley, M.B. Camb., Middlesex; F. J. Hayden, M.B. Melb., Univ. Coll. and Middlesex; A. J. Helfet, M.B. Liverp.; J. Howkins, M.B. Lond., Middlesex; W. R. Hunter, M.B. Liverp.; L. B. Joshi, M.B. Bombay, Middlesex; L. O. Knox, M.R.C.S. Eng., Univ. Coll. and Middlesex; C. D. Langton, M.B. Sydney, Univ. Coll. and Middlesex; L. W. Lauste, M.B. Lond., St. Thos. and Middlesex; R. S. Lawson, M.B. Melb., Univ. Coll. and Middlesex; A. W. Little, St. Bart.'s and Middlesex; J. B. McEwen, Glasgow and Middlesex; M. E. MacGregor, St. Thos.; R. G. Mackenzie, M.D. Toronto, Middlesex; R. J. H. McMahon, St. Bart.'s; A. G. McPherson, Camb. and St. Thos.; C. P. V. Menon, M.B. Madras, Middlesex; H. Milne-Redhead, Edin. and Middlesex; P. L. Mollison, Camb. and St. Thos.; W. R. M. Morton, M.B. Belf.; P. H. Newman, M.R.C.S., Middlesex; W. M. Nichols, M.B. Glasg.; K. I. Nissen, M.B. N.Z., Middlesex and Univ. Coll.; R. Officer, M.B. Melb., Univ. Coll. and Middlesex; G. H. C. Owens, M.R.C.S. Eng., St. Mary's; A. D. Popat, M.R.C.S. Eng., Bombay and Lond.; K. W. Powell, St. Thos.; S. H. Raza, Guy's; A. M. Rennie, M.B. Aberd., Middlesex; D. K. Sambrook, St. Thos.; G. N. Sen, M.B. Calcutta, Middlesex and Univ. Coll.; J. B. Sherman, M.B. Melb., Middlesex; A. A. Shorter, M.B. Sydney; S. F. Smith, M.B. Lond., St. Thos. and Middlesex; H. Sobhi, M.B. Cairo, St. Bart.'s; A. K. Talwalkar, M.B. Bombay, Middlesex; R. G. Talwalkar, M.B. Bombay, Middlesex; K. H. Taylor, St. Thos.; Margaret D. Thomas, Royal Free; K. B. Thornton, St. Thos.; O. G. Tanks, M.B. Sydney, Univ. Coll. and Middlesex; J. D. Wade, Camb. and Univ. Coll.; W. W. Wiggins-Davies, Camb. and St. Thos.; E. L. Wilson, M.B. N.Z.; and N. A. F. Young, St. Bart.'s.

University of Sheffield

L. A. Bull and William Ellis have passed Part II. of the final M.B., Ch.B. examination.

University of Liverpool

At recent examinations the following candidates were successful:—

M.CH. ORTH.

D. G. W. Brown, H. L. Davies, R. J. Katrak, G. E. Thomas, and E. F. West.

M.D.

R. S. Brock, S. Canter, J. G. Hailwood, and G. G. Warburton.

M.CH.

M. J. Bennett-Jones, F. R. Edwards, and J. A. Martinez.

M.B., CH.B.

Joan G. Jones (second class honours).

Part B (1924 Regs.).—C. H. H. Bryson and S. V. Cullen.
Part III. (1929 Regs.).—A. Cohen, H. W. F. Croft, Phillis Dingle, T. Laithwaite, L. Millward, and Moira Murray.

Part I.—S. Ball, J. L. Boyars, A. M. Bro Fraser, Doreen M. M. G. H. Shaw, and Henrietta Sloan.

Part II.—G. H. Ellidge, H. Gewater, Gwendollen M. Hughes, B. Polonsky, D. M. Rosenfeld, and R. B. Wright.

D.T.M.

V. F. Anderson, M.D., Alva A. Daniell, H. F. Ezzat, M. Farooq, A. Z. Hakeem, M. A. Hamid, M. A. M. Khalil, A. Kirshner, M. N. Lahiri, A. H. S. Mahallawy, Marjorie B. Morton, M. A. Nasr, R. J. O'Connor, K. O'Toole, R. V. Patel, S. K. Ting, M. A. el Tobgy, Mary A. Tomlinson, T. P. Tu, and E. B. Weeks.

Dr. A. Kirshner and Dr. R. J. O'Connor were recommended for Milne medals.

Royal College of Surgeons of Edinburgh

At a meeting of the College held on the 17th, with Mr. Henry Wade, president, in the chair, the following candidates having passed the requisite examinations were admitted to the fellowship:—

Madhav Vinayak Bhajekar, M.B. Oxon.; John Mark Carnow, M.B. Glasg.; Bernard Stringfellow Carter, M.R.C.S. Eng.; Thomas Beveridge Davis, M.B. N.Z.; Leonard Leon Jozel, Antoine de Rynck, M.R.C.S. Eng.; M.B. Edin.; Gilbert Forbes, M.B. Glasg.; Gillies, M.B. Leeds; Alan Mostyn Bradford Grant, M.D. Sydney; Ralph Clifford Hunter, M.B. Sydney; Claude Wilfred Alfred Kimbell, M.B. N.Z.; William Lamont, M.B. Glasg.; John Cyril McFarland, M.D. Liverp.; Neville Jennings Nicholson, M.B. Edin.; Charles Justly Probyn Pennors, M.R.C.S. Eng.; Isaac Victor Rogoff, M.B. Cape Town; Ian Harry Macgregor Seex, M.B. Edin.; John Love Steele Scott, M.R.C.S. Eng.; Andrew Copeland Taylor, M.B. Toronto; and Lennard Gilmour Travers, M.B. Melb.

University College Hospital Medical School

On Friday, Feb. 28th at 5 p.m., Dr. Cecil Price-Jones will deliver the eleventh Sydney Ringer lecture at this school. He will speak on the sizes of red blood-cells. Sir Robert Muir, F.R.S., will preside, and the lecture is open to all medical practitioners and medical students.

University of London

At a meeting of the senate held on Dec. 18th Dr. Thomas Nicol was appointed to the university chair of anatomy King's College.

Dr. Nicol is 35 years of age and was educated at Glasgow, graduating as M.B. with commendation in 1922. After holding house appointment at the Western Infirmary, Glasgow, and demonstratorship of anatomy at the university, he became lecturer in regional anatomy and senior demonstrator. In 1925 he was appointed senior lecturer, and for a time he has been acting head of the department of anatomy in the university. Dr. Nicol's contributions to medical journals have included experimental studies of reproductive physiology. In 1925 he was admitted to the fellowship of the Royal College of Surgeons of Edinburgh; he became D.Sc. Glasg. in 1934 and D. with honours last year.

The degree of D.Sc. in anatomy was conferred on Mr. D. M. Blair and Prof. H. H. Woollard. Dr. MacD. Paterson and W. A. Steiner, of Guy's Hospital, have passed the third examination for the B.D.S. degree, the former with distinction in orthodontics.

National University of Ireland

At recent examinations in University College, Cork, the following candidates were successful:—

M.B., B.Ch., B.A.O.

O. T. D. Loughnan (first-class honours): William Kearney, J. J. Sayers (second-class honours): Vincent Bennett, William Kearney, Michael Kirwan, Owen Loughnan, Cornelius McGrath, Samuel Nathan, V. J. O'Sullivan, William O'Sullivan, Bridget F. Jordan, T. J. Seavers, and Catherine M. Sullivan. Part I.—John O'Sullivan, Margaret M. M. Reynolds, Gerald F. Russell, John Russell, and Helen P. Tracey.

D.P.H.

D. F. Burke, T. G. A. Carroll, R. A. Good, M. J. Kennefick, J. P. Morehan, J. J. Murphy, J. P. O'Leary, and Elizabeth J. H. Phipps.

Royal Sanitary Institute

In 1936 this institute will make an award of the Henry Baron Snell prize to the writer of the best essay on improvements in the construction or adaptation of sanitary appliances. Competitors are asked to submit essays which are not merely accounts of developments which have taken place but which present constructive suggestions. Further particulars may be had from the secretary of the institute, 90, Buckingham Palace-road, London, S.W.1.

Memorial to Dr. Dan McKenzie

To perpetuate the memory of the late Dr. Dan McKenzie a fund is being raised to name a room after him in the new nurses' home at the Central London Throat, Nose, and Ear Hospital, with which he was intimately associated for over thirty years. Gifts should be sent to the chairman at the hospital (Gray's Inn-road, London, W.C.1).

Demonstrations of Contraceptive Technique

On Thursday, Jan. 2nd, at 2.30 P.M., a practical demonstration of the technique of the use of a variety of contraceptive methods will be given by Mrs. Marie Stopes, D.Sc., and Dr. Evelyn Fisher at the clinic of the Society for Constructive Birth Control. Medical practitioners and senior students should apply in writing to the hon. secretary at the clinic, 103, Whitfield-street, London, W.1.

Christie Hospital and Holt Radium Institute, Manchester

At the annual meeting on Monday Dr. E. Bosdin Leach, chairman of the medical board, spoke of steady progress made in dealing with cancer, and quoted Dr. Veitch Clark's description of work in progress at Manchester University as the only piece of work preventive of cancer that had yet been done. Mr. H. S. Souttar, who delivered an important address, began by recalling that it was in Manchester that he first learned of the great results that could be obtained by the use of radium in the treatment of cancer. In the Christie Hospital, he said, Manchester had a centre the work of which was not excelled anywhere in Europe. Mr. F. P. Nathan remarked that when the new hospital was built he and others had feared that there would not be patients forthcoming to fill it, but they had two deep X ray therapy plants fully occupied; and it would soon be necessary to set up two more, with the buildings capable of holding them.

THE King has conferred the Bar to the Order of Mercy on Colonel R. J. Blackham, C.B., M.D.

Royal Medical Benevolent Fund of Ireland

The annual meeting of this fund was held in Dublin on Dec. 13th, Dr. J. C. Martin presiding. The annual report, submitted by Sir John Moore, hon. secretary, expressed regret that the subscriptions, had shown a falling-off since the previous year of nearly £60. There had been a revival of the County Cork branch where there were some 50 new subscribers. In speaking on the report, Mr. T. Hennessy urged that the State should provide pensions for the widows of its medical officers.

International Congress of Physical Medicine

The sixth international congress of physical medicine will be held in London from May 12th to 16th under the presidency of Lord Horder. The congress has been divided into six sections (kinesitherapy, physical education, hydrotherapy and climatotherapy, electrotherapy, actinotherapy, and radiotherapy and radium therapy), and the three main subjects for discussion will be the physiological and biological study of physical agents, the clinical indications of the different methods of physical treatment, and the benefits and proper use of exercise in the healthy, and the teaching of physical medicine in the different countries. The hon. secretary is Dr. Albert Eidinow, 4, Upper Wimpole-street, London, W. 1.

Camp into Hospital

Redmires Camp is to be converted by the Sheffield corporation into a hospital for mental defectives. In recent years it has been used as a small-pox hospital, but it was built in 1914 for the training of the City Battalion, and has also served as a camp for German prisoners.

Births, Marriages, and Deaths

BIRTHS

BEDDARD.—On Dec. 18th, the wife of J. R. J. Beddard, M.R.C.S. Eng., of Frome, of a son.

HARVEY.—On Dec. 18th, at Satton, Surrey, the wife of Dr. T. Blair Harvey, of a son.

LING.—On Dec. 13th, at Streety, Staffs, the wife of Dr. Thomas M. Ling, of a daughter.

PHILLIPS.—On Dec. 19th, at Wilbraham-place, S.W., the wife of Dr. W. H. Phillips, of a son.

SMALLSHAW.—On Dec. 15th, at Epsom, the wife of Dr. D. B. Smallshaw, of a son.

WATERS.—On Dec. 16th, at Bombay, the wife of Captain H. S. Waters, M.B. Camb., F.R.C.S. Eng., L.M.S., of a daughter.

DEATHS

CHESNEY.—On Dec. 20th, suddenly, at Palma de Mallorca, Spain, Lillian Mary Chesney, M.B. Edin., D.P.H., second daughter of the late General Sir George Chesney, K.C.B., R.E.

COLLIER.—On Dec. 21st, at Oxford, William Collier, M.D. Camb., F.R.C.P. Lond., aged 79.

DAMPIER-BENNETT.—On Dec. 20th, suddenly, at Sidmouth, Arthur George Dampier-Bennett, M.R.C.S. Eng., M.O.H. for Sidmouth, aged 65 years.

FERNANDO.—On Dec. 18th, in London, Sir Hilariion Marcus Fernando, M.D. Lond., of Colombo, Ceylon, aged 71.

HART.—On Dec. 18th, suddenly, at North Walsham, Norfolk, James Duncan Hart, M.C., M.B. Glasg., aged 52.

MCILROY.—On Nov. 22nd, suddenly, at Kendall, New South Wales, John Black McIlroy, M.R.C.S. Eng., L.R.C.P., L.S.A., second son of the late Major and Mrs. McIlroy, of Woolwich.

PEPPER.—On Dec. 18th, at Sidcup, Kent, Augustus Joseph Pepper, M.S. Lond., F.R.C.S. Eng., aged 86.

PHELPS.—On Dec. 14th, at Tonbridge, Kent, Arthur Martin Phelps, M.D. Camb., aged 86.

RYAN.—On Nov. 30th, at 9, East Hill, Colchester, Essex, Joseph Michael Ryan, M.B. Durh., L.R.C.S.I. & L.M., L.A.H. Dublin, aged 82 years.

WESTMACOTT.—On Dec. 20th, at his residence, Colonel Frederic Hibbert Westmacott, C.B.E., B.Sc., F.R.C.S. Eng., T.D., D.L., Knight of Grace of the Order of St. John of Jerusalem, late R.A.M.C. (T.), Consulting Aurist and Laryngologist, Manchester Royal Infirmary, aged 68.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

MEDICINE AND FAITH *

By C. LOUIS LEIPOLDT, F.R.C.S. Eng., D.Litt.

LECTURER ON PEDIATRICS, UNIVERSITY OF CAPE TOWN; VISITING
PEDIATRIC PHYSICIAN TO THE NEW SOMERSET HOSPITAL;
EDITOR OF THE SOUTH AFRICAN MEDICAL JOURNAL

MEDICINE I assume to be the art of healing and tending the sick, founded on principles formulated by the experience of centuries of study of the human body in health and disease. It is an art and not a science, although ancillary to it are the definite sciences of physiology, anatomy, biochemistry, psychology, and pharmacology. Like all other arts it has its limitations, chief of which is its inability to systematise its experience into an incontrovertible creed. It is, and must be, largely empirical, its experience founded on trial and error methods assisted by such help as it may obtain from the exact sciences. The fact that a man practises medicine and is a registered medical practitioner does not imply that he is bound to limit his practice to one method, however orthodox, or is debarred from using whatever help he may obtain from other methods, always providing that he makes no secret of these methods and does not vaunt his own fads as decisively superior to those of his fellow practitioners. The register, in fact, is a statutory roll, provided by the Government for the safety of the public, of such practitioners of healing as have gone through that preliminary training which the State demands from those who are allowed to hold public appointments, sign death certificates, or sue for their fees.

A definition of faith is less easy, but I may perhaps be permitted to adopt the familiar definition: "Faith is the faculty that enables us to realise the unseen." It is not a comprehensive, or even a satisfactory, definition but it differentiates between matters on which we can exercise our scientific judgment and those which we cannot weigh and measure by scientific standards.

DIVORCE OF MEDICINE FROM THE CHURCH

In the remote past, medicine and magic were, we know, synonymous terms, and the practitioner of medicine was primarily concerned with these imponderables that are now considered to be more in the province of the priest than in that of the doctor. That is still the case in many uncivilised communities. When medicine became recognised as a separate art, it emerged from the shadows of the temple. After a few centuries it again migrated to church or monastery, and among the greatest exponents of our art have been monks and theologians, like Maimonides whose eighth centenary both theology and medicine celebrated this year. With the decline of monasticism in the west, medicine once more assumed an independence which it has since maintained.

One may doubt if it has been altogether a gainer by this determined divorce from the Church. The attitude of the Church—and by the church I mean not one denomination or sect, not one system of religion, but all organisations that admit the validity of what Burckhardt called "primordial images" and Jung styles *Urbilder* or archetypes, as a basis for an ethical creed—the attitude of the church

towards healing has always been definite and logical. It is based on the belief that pain and disease are realities, and as such amenable to objective treatment. All religions recognise that mankind has been given knowledge and skill to heal, and that the professional healer, the physician, has qualified himself by training and experience, to deal with the mass of disease to which mankind is subject. But all religions, too, have assumed that spiritual values count for more in man's life than what is material, and that while healing is usually an affair of mundane arrangement, it is occasionally one of faith, to be managed by the direct interposition of non-material forces. These are assumptions utterly beyond argument. They rest on that conception of faith that admits that what is impossible may happen. At first sight it may seem that medicine and the church, which makes such assumptions, must be directly antagonistic, and if medicine were an exact science that would undoubtedly be the case. But medicine is not an exact science: *it is not even a science; it is an art which enshrines* certain basic facts, or what it takes to be facts, in an empirical system that can never be static but must continually yield to the force of new facts as they are elicited.

PROGRESS SLOWING UP

Medicine to-day is marking time. To the layman, fed on the sensational tit-bits doled out by the lay press, that may seem an over-statement, but it is nevertheless the truth. In surgery we have, I think, reached the limits, wide as they were, which the discoveries of Semmelweis and Lister marked. The old surgeons thought of operations which their technique was too poor to enable them successfully to carry out. We have progressed beyond them, although, as a matter of fact, no one has yet attempted some of the operations suggested by their flights of imagination—the intra-abdominal reduction of a spinal dislocation for instance. But surgery is tending to become more conservative, and in pure medicine our progress has been slow, although in the realm of preventive medicine, and in biochemistry we have every reason to be proud of what has been achieved. Sir William Gull, one of the most acute medical men of his day, refused to believe in the possibility of scientifically defining disease, and to-day most of us would support him in that refusal. We discourage our patients from talking about disease, although we pander to their itch for definitions by labelling their illnesses by high-sounding names wherever we can—and sometimes when we honestly can't. For the layman as well as for the doctor it is much more practical to speak of pain and suffering. They are not tangible things, it is true, but they are concepts of subjective disturbance which everyone knows. As doctors we do not know the real significance of pain in every case where we encounter it. Much has been written on it; it has been held to be Nature's warning of impending disaster, a clamant call for rest, but unfortunately it is a warning sometimes absent in the gravest conditions, such as cancer, and vociferous in some of the least importance such as a superficial burn of the finger. To the doctor, however, it is a reality with which he comes into daily contact, and which he can often ameliorate and sometimes conquer. To the layman pain is the best sign of disease.

From time to time the public is stirred by stories of wonderful new ways of healing, told, mostly, to

* A public lecture (abbreviated) delivered at Grahamstown, South Africa, on Sept. 30th, 1935.

the disparagement of medical men. At the present time Australia is much concerned about a new method of treating infantile paralysis. In this disease we try to improve the condition of the paralysed limbs, but we cannot, by any method known to us, restore the integrity of the end station in the spinal marrow. Recently a nurse in Australia announced that she had found a method of treatment by means of which these paralysed children could be made more or less normal. The medical profession at once declared itself willing and eager to coöperate with her, and Sir Alfred Cilento induced the Australian Government to provide her with all facilities to prove the efficacy of her method. The new treatment was immediately investigated, and although it showed some points of superiority, it was found to be by no means so certain or so easy a method of alleviating the results of infantile paralysis as those already in use.

FUNCTIONAL AND ORGANIC DISEASE

Medical men have for centuries drawn a useful although perhaps unscientific line between functional and organic diseases. By functional disease we mean a condition that disarranges the normal functions of the body without leading to a demonstrable change in any organ or tissue. By organic disease we mean a condition that injures an organ or tissue in such a manner that we can prove that injury by chemical or microscopical tests. A transient headache is an example of the first; a broken leg of the second. The distinction between the two categories is practically useful but it is not philosophically sound, for disturbance of function must depend on some fault in the machinery, and although that fault may at present be undetectable by our means of investigation, we cannot assert that it does not exist. The insistence on the validity of these categories has perhaps done harm both to our medicine and our faith, for it has led us to limit the possibilities of healing by faith to diseased conditions that fall into the first category. Every experienced doctor knows of functional disease that has been alleviated by methods outside the purview of orthodox medicine, and of individuals whose very presence in the sick room is of benefit to the patient; some may even go further and claim that they know men and women who possess remarkable powers of healing. The belief in this charismatic gift, this power of healing inherent in some individuals, is as old as history, and is limited to no country or class; it is practically universal. The opportunities to test such individuals are few, and so far as I know, no scientific investigation of their powers has been attempted. The Church—and again use that term in an all-embracing sense—has always believed in such powers. The great religious leaders have all possessed it, and their records abound with instances where they have exercised it beneficially. Experience, through centuries, has taught us two vital facts. One is that there can be no healing without faith, without that conviction that rests must inevitably follow no matter how impossible such results may seem. On the recognition of this essential primary fact all great spiritual healers have based their practice. "According to thy belief, be thou healed" is recorded of Buddha when he cured the blind man, and all the examples of spiritual healing recorded in the Christian scriptures show that iswerving faith on the part of the sufferer was an essential pre-condition. The second important fact that in no recorded case of faith healing can we truthfully speak of a miracle in the sense that it was a complete and unequivocal

reversal of natural law. In every hospital, in every psychiatric clinic to-day such miracles are performed by appropriate suggestion, sometimes conscious, sometimes unconscious, without anybody considering that there has been any reversal of natural laws. Medicine has not denied, and cannot deny, the possibility of such latent power, for many of its masters have themselves cured patients by unorthodox means, although to tell the truth some of them like Werlhof and Sir Astley Cooper seem to have been somewhat shamefaced about their share in the cure.

Again, we have the proved fact that sick people have been cured by prayer, by relics, by suggestion, by faith. Hitherto the faculty has always assumed that these cures were of purely functional disease, and even yet there is a general feeling that the allegations about the cures of organic disease cannot be substantiated. But the carefully documented evidence of Dr. le Bec, in his book *The Medical Proof of Miracles*, which describes three cases of the cure of organic disease at Lourdes, and the equally careful records of Dr. Elwood Worcester of the Emmanuel Church movement, must force us to reconsider our attitude in this matter, and may lead to a readjustment of our views on faith-healing.

ATTITUDE OF MEDICINE TO FAITH-HEALING

What, then, is the present attitude of medicine towards faith-healing? That of the Christian Church is concisely expressed in the thirteenth and fourteenth verses, chapter v., of the Epistle of St. James.

Is there among ye that suffers? Let him pray.

Is there one that is sick? Let him call in the elders of the church that they may pray over him having anointed him in the name of the Lord.

These texts clearly indicate that pain and disease are to be regarded as realities, and not, as the Christian Scientists would have us believe, as mere figments in a perfect world. In the 1908 report of the Lambeth Conference Committee on healing, a committee on which the present Archbishop, then Bishop of Grahamstown, sat, it is stated:—

"We look forward confidently to an orderly movement towards the adjustment of these three aspects of the work of healing, physical science, psychology and religion."

Like the Church of Rome from time immemorial, all Christian churches have confessed their approval of healing by faith, but none has denied, as some Christian and non-Christian societies have denied, the efficacy of medicine. The Church of Rome has for many years worked in coöperation with medicine at Lourdes, and it is highly interesting to hear of the elaborate precautions taken by the medical committee to prevent open fraud. The Emmanuel movement too has been worked in partnership with medicine, and Dr. Elwood Worcester has stated repeatedly that—

"From the beginning we have associated ourselves with competent medical men and surgeons. Indeed, had such coöperation been refused I should not have dreamed of assuming responsibility for the sick in mind and body. For many years most of our patients have been sent us by physicians, and in all cases which involved more than the need of moral and spiritual advice we have left no stone unturned to procure the best diagnosis and medical care possible."

The attitude of the Church then may be said to be friendly towards medicine. What is our attitude towards these mysteries of faith-healing? There was a time when, through our ignorance and immodesty, it was blatantly antagonistic, and one can cite passages from the writings of men who were masters

of clinical medicine and yet illiberal and intolerant enough to condemn faith-healing as gross superstition and imposture. But the scientific attitude towards healing by faith is to-day exactly what it was in the time of Bacon, who in his "*Sylva Sylvarum*" has summarised it very clearly as follows:—

"The problem therefore is whether a man constantly and strongly believing that such a Thing shall be, as that he shall recover from a sickness, it doth help anything to the Effecting of the Thing itself. And here again we must warily distinguish. For it is not meant that it should help by making a man more stout or more industrious, in which kinde constant beleefe doth much, but merely by a secret operation or binding or Changing the Spirit of Another. And in this it is hard to make any new experiment. For I cannot command my Selfe to Beleefe what I will, and so no Triall can be made. Nay it is worse; For whatever a Man Imagineth doubtingly, or with fear, must needs do hurt, if Imagination have any power at all; For a Man representeth that oftener that he feareth than the contrary."

We have progressed since then. Bacon, learned as he was in philosophy, knew nothing about modern concepts such as the subconscious and the collective unconscious of Jung, of primordial images, of a rational explanation of mania, hysteria, or a simple skin rash. Yet our position is to-day very much the same as it was in his time when it comes to defining our attitude towards faith-healing. It is, and must remain, an attitude of tolerant scepticism, but it need not necessarily be one of opposition, antagonism, and enmity. It must be the same attitude that we take up when we are confronted with the claims of new methods of cure when these claims have not yet been proved—an attitude of perfect willingness to test the new methods, to apply them in selected cases, and to learn by experience how useful or useless they may ultimately prove.

I do not think that is an attitude to which laymen need take exception, but they may certainly call upon us to show that it is one which we adopt without prejudice. The proof should lie in our willingness to coöperate with the Church and to identify ourselves professionally much more actively with spiritual healing than we have yet done. My colleagues, with whom I sometimes discuss this subject, object that spiritual healing falls outside the sphere of our art because it conforms to no standard of scientific measurement. That objection is unsound, for, as I have already said, our art accepts many other things—empirical drugging for example—that cannot be scientifically defended. Another objection is that these unorthodox methods are as old as the human race, and if there is anything in them they should by this time have been proved to the satisfaction of everyone concerned. But our understanding of them has considerably improved within the past fifty years, and we are now in a position to test them far better than we were before. To shut our eyes to them, to deny that they do produce results, would be illogical, as well as foolish.

A PRACTICAL SCHEME IN BEING

So far as I know there is only one medical faculty that has tackled the problem in a practical way, and the results it has achieved are interesting. A year ago the University of Colorado instituted a psychiatric liaison service between its school of medicine and its department of psychology. The object of the scheme, as set forth in the official syllabus, is:—

To establish psychobiology as a scientific and integral working part of the professional thinking of physicians

and students of all branches of medicine; to make physicians and students aware of the opportunities offered them by every patient, no matter what complaint or ailment is present, for the utilisation of a commonsense psychiatric approach for the betterment of the patient's condition and making that patient better fitted to handle his problems; to instil in physicians and students the need the public has for a more tangible and practical conception of personality and sociological functioning, not so much in the sense of prevention of mental and personality disorders *per se* but rather in the sense of the prevention of false-thinking, misunderstanding, folklore and taboos that make it difficult for him to accept help or to allow the physician to be of help.

In six months' time this service is stated to have proved its usefulness. Nearly 20 per cent. of all patients on the medical side were referred from the out-patient department to the psychiatrist. In the hospital, 10 per cent. of all medical cases admitted, 3 per cent. of all surgical cases, 2 per cent. of all obstetrical cases, and 3 per cent. of all pædiatric cases were referred for what we may call "spiritual healing." Roughly 12 per cent. of all such referred patients showed evidence of organic disease. A medical journal, commenting on these statistics, writes:—

To date it is the consensus of opinion that this new project has done much to decrease patients' days in hospital and dispensary, and has through its psychobiological teaching only added more respect for the methods of the natural and basic sciences.

Here, then, we have a practical scheme, successfully tried, although necessarily on a limited scale. Its success is such that one is encouraged to hope that our own medical schools and universities might progress in the same direction, and institute something similar whereby the present gap between medicine and faith may be bridged.

THE PRICE OF COÖPERATION

But in return for coöperation from our side we must have knowledgeable coöperation from the public, from the Church, as well as from the laity.

Some years ago, when the Church organised the Hickson campaign of healing, there was a splendid opportunity for such helpful mutual assistance that might have led to tangible results. Unfortunately this was not enlisted, and although it may be true that goodwill it was given no opportunity of testing its sympathy, while the emotional surroun- dings of the mission were of such a nature that many of us were frankly repelled. I was at that time chief medical inspector in the Transvaal, and many parents came to the school clinic to ask my advice as to whether their children should be sent to the mission for treatment. We selected 24 children, half of whom were suffering from definite organic disease, and half of whom had some functional condition, or what was regarded as such. Of these two children were benefited; both were cases of migraine, and both relapsed a few weeks after the emotional exaltation of the service. One had died down. None of the others showed any signs of improvement, although six of them were later on much improved by ordinary medical treatment. I saw several children, certified as defective at birth, brought by their parents for exaltation, who were said to be cured. In none was there any definite improvement, except what could be ascribed to the emotional exaltation produced by the service. I feel sure that Mr. Hickson, whose charismatic gift was undoubtedly successful in healing many suffering from a proper medical committee, and whose cases, his success would have been greater if he had been assisted by a proper medical committee, and his success would have been greater if he had been assisted by a proper medical committee, and his success would have been greater if he had been assisted by a proper medical committee.

The public may give their coöperation by discouraging the quack and the charlatan, who by claiming to practise the art of healing without training and

ledge of its limitations exploit the public for his special benefit. There is no country in which quackery is more rampant than in South Africa, where the consumption of quack remedies is so high per head of white population; where the charges for quack treatment are enormous. We have all kinds of quackery, ranging from semi-scientific electrical treatments, that claim to diagnose and cure disease by oscillatory currents, to the pretentious cancer curer and the quack healer of the blind. There is probably no disease which to the lay mind connotes more suffering and agony than cancer. It is therefore natural and understandable that when the profession is as yet ridiculously handicapped in its fight against malignant disease, the sufferer should fly for salvation to the quack who promises cure. In South Africa, unfortunately, the cancer curer has a fertile field for exploitation.

So potent is the faith in these cancer quacks that the friends of a notorious exponent of the fraud petitioned the Cape Parliament, some years before Union, for permission for her to carry on her work without licence of the law, and succeeded in impressing our legislators to the extent that a select committee was appointed to investigate her method and alleged cures. The report of that select committee is a revelation to those who are unaware to what extent the public is imposed upon. There was no evidence that the method employed had cured or even alleviated cases of undoubted cancer, but the contrary it was shown that its employment had caused much pain and suffering to the victims. The alleged cures were cases of non-malignant disease which could more easily, expeditiously, and painlessly have been cured by other means.

Next to cancer, perhaps the greatest fear of the public is blindness. It is understandable that a patient feels that there is something wrong with his eyesight he should be attracted by the advertisements, usually speciously worded, of those who claim more than what medicine dares promise. In a manner in which the public is exploited by the sight-testing optician who advertises is so detrimental to the public welfare that again we as a profession should be neglectful of our duty if we failed to utter warning. To treat eye disease scientifically demands specialised knowledge. We have recognised that by insisting on special study for those who, as ophthalmic surgeons, are entrusted with the task of treating eye diseases and estimating the errors of refraction that demand, for their correction, the fitting of suitable glasses. Sight testing is not a mechanical job that can be effectively done with the aid of apparatus; to be well done it calls for a knowledge of medicine, an acquaintance with nervous and constitutional disease such as, under present conditions, only the trained ophthalmologist possesses. There are many of us who go about wearing spectacles that are unnecessary, or that are useless if necessary, because we forget that fact and have recourse to sight-testing opticians instead of to the ophthalmologist.

The popularity of eye exercises and the publicity given to the methods of eye-dealers whose first counsel is "wear your glasses" is easily explainable when we consider the fact that a large percentage of the spectacle-wearing public needs no glasses and would never have been compelled to wear them had it gone to the ophthalmologist for an opinion. Our considered advice to the public should be that when there is anything amiss with our eyes we should consult the ophthalmologist, and take his opinion to the optician. It is the function of the ophthalmologist to supply us with glasses, not to diagnose our conditions and treat them. When he presumes to do so he can only be partly effective, for he is not per-

mitted to use drugs, which are in some cases indispensably necessary for correct sight testing, and he encroaches upon a sphere of activity which the legislature, rightly or wrongly, has demarcated for medical men duly registered as such.

I have spoken about these two subjects, cancer curers and the vendor of glasses, because they emphasise the necessity to educate the public to distinguish between realities and apparent realities. Towards that education the efforts of all who are cultured should be directed, and the task must not be left to the medical profession, but there should be knowledgeable co-operation between the doctor and those whom in sickness he serves. By admitting that faith has a share in shaping our destinies and that the influence of the soul upon the functions of the body is something that our art should employ in its practice and methods of healing, we deny no canon of our teaching, though we may have to modify some of our views. In the matter of spiritual healing there is something more than probability; there is proof of a kind to be strengthened by further investigation such as can only be achieved by teamwork. The medical profession in this country, I feel sure, would welcome such team-work, and would do all in its power to make it effective by supplying not merely destructive criticism but constructive suggestion, clinical experience, and practical indications for the benefit of those who may be helped by spiritual healing.

MORE ABOUT THE SOYA BEAN

FOR 5000 years the soya bean has been the staple food of the inhabitants of Eastern China and their safeguard against famine. A small book¹ has now been published to show that it is possible and advisable to grow it in England. The bean contains 46 per cent. of protein and vitamins A, B, D, and E, and it is suggested that it would be the mainstay for feeding a country in time of war. The seed may be ground into flour which is used for diabetic, infant, and breakfast foods. The oil is employed in making butter and large substitutes and soap, while the juice becomes vegetable milk in condensed and powder forms, and also cheese. The range of by-products is almost incredible, the chief being cattle-feed, enamels and varnishes, rubber substitutes, linoleum, printing inks, celluloid, petroleum, explosives, glycerin, and some parts of motor-cars.

The nitrifying bacteria required by the soya bean are, it is stated, not present in English soil, but can be introduced artificially by inoculating the seed before it is sown. The bacteria, living within the nodules attached to the roots of the plants, draw in from the air large quantities of free nitrogen and convert it into nitrates for the nourishment of the plant: as the surrounding soil becomes infected inoculation of the seed may be discontinued. If phosphates, potash, and lime are present the bean will grow in sand or even cinders.

In 1932 Mr. Henry Ford failed to raise a soya crop at Boreham in Essex; but previously Mr. J. L. North, later curator of the Royal Botanic Gardens, had successfully cultivated the plant in the Thames Valley to the west of London after 18 years' experiment. Mr. Ford enlisted his services and a quantity of North's special acclimatised seed was sown from which good yields were harvested in 1933 and 1934. During these trials it became evident that the poorer types of soil suited the bean better than rich earth, which apparently weakened the plant's resistance to frost.

¹ Bowdidge, E.: *The Soya Bean: its History, Cultivation (in England), and Uses*. London: Humphrey Milford, Oxford University Press, 1935. Pp. 98. 6s.

AEROPHAGIA

A. R. Calatayud and E. L. Muñoz¹ in reporting a case of aerophagia point out the value of X ray examination in making a differential diagnosis, and describe the technique advised. The condition has to be distinguished (1) from physiological aerophagia, an increase in the amount of air with the food, which is seen in (2) from false aerophagia associated with the respiratory tract, &c., causing dyspnoea; (3) from oesophageal lesions; and (4) from the modifications in the amount of air present in the stomach in hypertonia and hypotonia. They describe the case of a man aged 60, with no past history or family history of importance, except for occasional bronchitis, who complained of discomfort and fullness after meals, mild epigastric pain, and eructations. He weighed 13½ st., and appeared excitable and neurotic. Pyorrhoea was present. The abdomen was rather distended. On X ray screening, the stomach was found to be orthotonic; motility was slightly diminished, and emptying was rather slow. Air could actually be seen entering the stomach by successive acts of swallowing. The air-space grew steadily larger until a fresh eructation partly emptied it, and the air swallowing then recommenced, in a constantly repeated cycle. The nature of his trouble was explained to the patient, and apparently he was able to control the habit, since it is reported that following general treatment and treatment for the pyorrhoea he was cured of the condition in about two months.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
WEDNESDAY, Jan. 1st.

Surgery, 8.30 P.M. Mr. G. H. Steele: Retrograde Oesophagoscopy. Dr. H. L. Marriott and Dr. A. Kelwick: Continuous Drip Blood Transfusion. Mr. C. Jennings Marshall: Treatment of Diverticulitis of the Colon.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

FRIDAY, Jan. 3rd.—5 P.M. (Mechanics Theatre, University College, Gower-street, W.C.). Dr. G. O. Barber: School Pressure in Work and Play.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

THURSDAY, Jan. 2nd, and FRIDAY.—Afternoon course in dermatology at St. John's Hospital, 5, Lisle-street, Leicester-square, W.C.

Appointments

COOLICAN, J. H., M.B. Dub., F.R.C.S. Irel., F.R.C.S. Edin., has been appointed Hon. Visiting Surgeon to the Mercers' Hospital, Dublin.

DOBBS, R. H., M.B. Camb., First Assistant in the Children's Department of University College Hospital.

DONOVAN, JOHN, M.B. Leeds, F.R.C.S. Edin., Resident Surgical Officer at the City Hospital, Nottingham.

EVANS, E. H., M.D., M.R.C.P. Lond., Resident Medical Officer at the City of London Maternity Hospital.

HARKNESS, ISABELLA, M.B. Glasg., D.P.H., Assistant Medical Officer for Maternity and Child Welfare for Nottingham.

JONES, D. J., M.B. Wales, D.P.H., Assistant County Medical Officer of Health for Warwickshire.

KINBELL, C. W., M.B., Assistant Resident Medical Officer at the City of London Maternity Hospital.

LIVINGSTONE, GAVIN, M.B. Lond., F.R.C.S. Eng., to the Metropolitan Hospital.

MELROSE, M. M., M.R.C.S. Eng., Hon. Paed. Herefordshire General Hospital.

MILLS, C. T., M.B. Manch., Hon. Anaesthetist to the Infirmary, Worcester.

MORLAND, ANDREW, M.D., M.R.C.P. Lond., Physic. patients to the Hôpital et Dispensaire Français, D.

PATRICK, L. B., M.B., F.R.C.S. Edin., M.C.O.G., A. Hon. Surgeon to the Jessop Hospital for Women, S.

PERROT, H. S., M.B. Dub., Hon. Anaesthetist to the H. shire General Hospital.

SMITH, E. R., M.D. Liverp., D.P.H., Deputy Medical Officer and Deputy School Medical Officer for S.

WILLMOTT, B. M., M.B. Camb., F.R.C.S. Eng., Hon. Surgeon to the Birmingham Maternity Hospital.

WINDEYER, B. W., M.B., F.R.C.S. Edin., D.M.R.E., Officer in Charge of the Department of Radiology at the Middlesex Hospital.

Royal Free Hospital.—The following appointments announced:—

POWYS, M., M.B. Lond., District Obstetric Assistant.

STEWART, A. M., M.D., Medical Registrar.

WHITE, M. MOORE, M.B. Lond., F.R.C.S. Eng., Logical Registrar.

BECK, D. J. KINLOCH, F.R.C.S., Surgical Registrar.

Certifying Surgeon under the Factory and Workshop Dr. P. C. PARR (Marlow District, Buckingham).

Vacancies

For further information refer to the advertisement in Banbury, Horton General Hospital.—Res. M.O. At £150.

Bath, Royal United Hospital.—Hon. Anaesthetist.

Birmingham City Mental Hospital.—Jn. Asst. M.O.

Birmingham, Royal Cripples Hospital.—Res. H.S. of £200.

Brighton Municipal Hospital.—Third Res. Asst. M.O.

Cambridge, Addenbrooke's Hospital.—H.S. At rate of £125.

Canterbury, Kent and Canterbury Hospital.—Two H.S. at rate of £125.

Capetown, Cape Hospital Board.—Radiologist. £1250.

Croydon General Hospital.—Hon. Neu. logist. Also Hon. Physician.

Dorchester, Dorset County Hospital.—H.S. At rate of £350.

Durham County Mental Hospital.—Asst. M.O. £350.

Eastbourne, Princess Alice Memorial.—Res. H.S. £150.

Edinburgh, Gilbert Bain Memorial Hospital, Lerwick.—and Consultant. £700.

Enfield Education Committee.—School Dental Surgeon.

Glasgow, Royal Faculty of Physicians and Surgeons.—Fell Examination.

Glasgow Royal Mental Hospital, Gt. travel.—Asst. Ph. £300.

Halifax Hospital for Infectious Disen. —Res. M.O. £300.

Hampshire County Council.—Asst. County M.O. £800.

Hospital for Consumption and Diseases of the Chest, Bro. S.W.—H.P. At rate of £50.

Hull Royal Infirmary.—Cas. O. At rate of £150.

Ilford Council Maternity Home.—Res. M.O. £350.

London Jewish Hospital, Stepney Green, E.—Out-patient £125.

London University.—Readership in Surgery. £800-£1000.

Manchester, Ancoats Hospital.—Res. Surg. O. £200.

Med. Reg. £50.

Manchester Royal Children's Hospital, Pendlebury.—Res. At rate of £125.

Middlesex County Council.—Tuber. M.O. £750.

Newcastle-upon-Tyne, Hospital for Sick Children.—Res. £250. Also H.P. and H.S. Each at rate of £100.

Nottingham General Hospital.—H.S. At rate of £150.

Rochdale Infirmary and Dispensary.—Sen. H.S. £250.

Rochester, St. Bartholomew's Hospital.—Cas. and Orthop. At rate of £175.

St. John's Hospital, Lewisham, SE.—Clin. Asst. to Elec. and Massage Dept.

St. Paul's Hospital, Endell-street, Colborn, W.C.—H.S. of £150.

Trans-Jordan.—M.O. £650.

Walsall General Hospital.—H.S. At rate of £150.

Warrington, County Mental Hospital, Winwick.—Asst. £500.

West Ham County Borough.—Radiologist. £250.

West Sussex County Council.—Asst. Tub. O. and £750.
